Figure 74-1. Tire service normally begins with a thorough inspection. Look for damage and wear on all surfaces of the tire. A—Insert a penny into a groove in the tire tread. If you can see the very top of President Lincoln's head, the tire tread is too worn and the tire should be replaced. B—A tire depth gauge can be used to measure the actual tread depth. If the tread depth is less than 1/8″ (3.175 mm), the tire may be unsafe and should be replaced.

Tire Impact Damage

Tire impact damage, also termed ***road damage***, includes punctures, cuts, tears, and other physical tire injuries. Drivers often run over road debris, potholes, hit curbs, and impact other objects that cause premature tire failures. Small air leaks can usually be repaired. However, even minor tire damage, cuts, air bubbles, and wear patterns require that the tire be replaced to be considered safe to drive. Some examples of tire failure are illustrated in **Figure 74-2**.

Florida Dept. of Voc. Ed.

Figure 74-2. These are typical types of damage found on used tires.

Tire Wear Patterns

A ***tire wear pattern*** (area of tread worn *off*) can usually be studied to determine the cause of the abnormal wear. Look at **Figure 74-3**.

Improper tire inflation, ply separation, incorrect wheel alignment, lack of periodic tire rotation, and an out-of-balance condition can cause excessive tire wear. By carefully inspecting the tire tread, a technician can identify worn steering and suspension parts that should be repaired before tire replacement.

Tire Inflation Problems

Correct tire inflation pressure is important to the service life of a tire. Proper inflation is needed so the full tire tread contacts the road, **Figure 74-4**.

Underinflation (low air pressure) is a common and destructive problem that wears the outer corners of the tread area. The low pressure allows the tire sidewalls to flex, building up heat during operation. The center of the tread flexes upward and does *not* wear.

Underinflation can cause rapid tread wear, loss of fuel economy, and possibly ***ply separation*** (plies tear away from each other). Ply separation causes the tire sidewalls to bulge outward and form an air bubble in the sidewall.

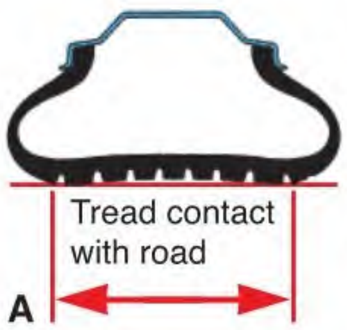
Overinflation (too much air pressure) causes the center area of the tread to wear. The high pressure

Copyright Goodheart-Willcox Co., Inc.

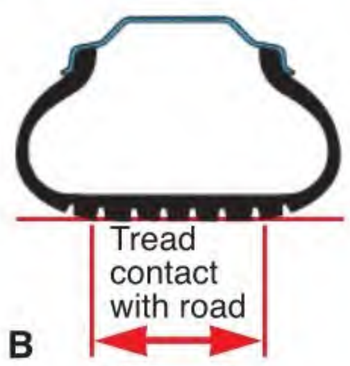
A–Feathering. This is caused by erratic scrubbing against road when tire is in need of toe-in or toe-out alignment correction.

B–Overinflation. Overinflation can cause fast centerline wear in bias and bias belted tires. In this case, center ribs get more contact with road than they should and wear much faster than outer ribs.

C–Underinflation. When a tire is underinflated, most of its contact with road is on outer tread rib, or shoulder, causing faster wear here than in middle. Be sure to check tire's air pressure.



D–One-side wear. Here's another type of alignment problem–excessive camber, which means tire is leaning too much to inside or outside of tread, and placing all work on one side of tire.



E–Cupping. This means the car may need wheels balanced, or possibly new shock absorbers or ball joints, or both.

Goodyear

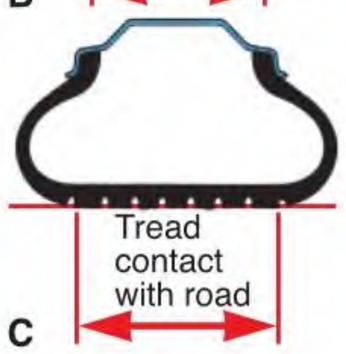


Figure 74-3. Tire tread wear patterns will help you identify the cause of rapid or abnormal wear. Study the patterns and the causes.

Underinflation–Causes excessive tire flex and heat buildup, risking failure. It also causes excessive wear on outer tread ribs.

Overinflation–Causes tires to ride hard and makes them more vulnerable to impact damage and weakening of tire body.

Proper Inflation–Correct profile for uniform contact with road which results in good tire performance.

Goodheart-Willcox Publisher

Figure 74-4. Tire inflation pressure is critical to tire life, vehicle handling, and ride.

causes the body of the tire to stretch outward. This pushes the center of the tread against the road surface, but lifts the outer edges of the tread off the road.

An overinflated tire produces a rough or hard ride. It is also more prone to impact damage. Use a tire pressure gauge to check inflation pressure if you suspect high or low tire air pressure.

Tech Tip

Remember that the tire inflation pressure on the sidewall is the maximum recommended pressure. The ideal tire pressure at a specific temperature is given in the owner's manual. This pressure depends on several variables, such as tire temperature, vehicle curb weight, suspension stiffness, and intended use.

With a properly inflated tire, the full tread area of the tire touches the road. The tire will wear evenly across the tread. This increases tire life and improves handling and safety.

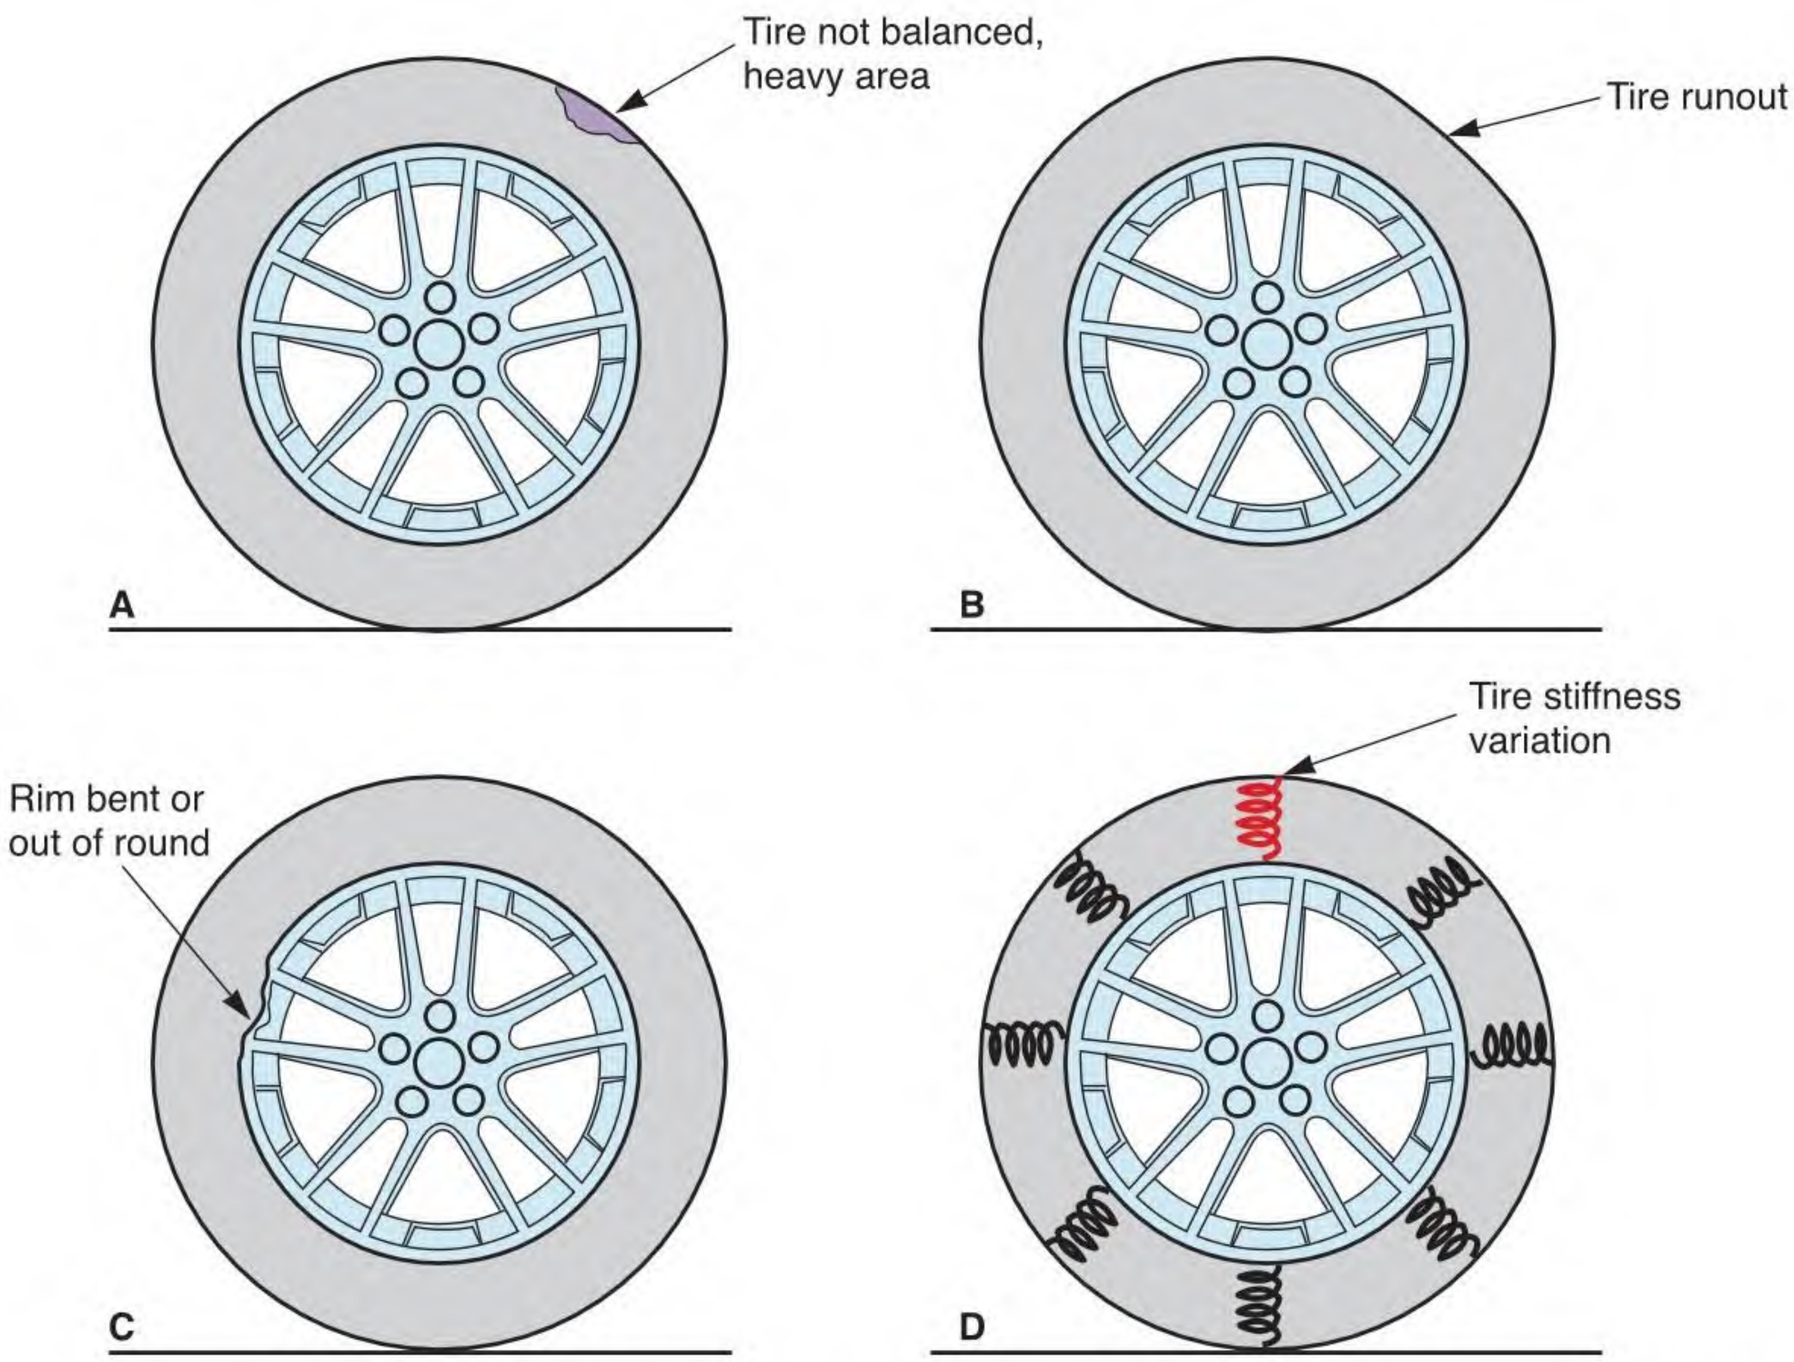
Copyright Goodheart-Willcox Co., Inc.

Steering wheel pull can be caused by uneven tire inflation. For example, if the left front tire (driver's side) is underinflated, the car will pull to the left. The partially deflated tire has greater rolling resistance, pulling the steering wheel away from the normally inflated tire, which consumes more energy.

Tech Tip

Keep tires inflated properly on every car you work on. Low tire pressure increases tire rolling resistance, fuel consumption, and tire wear. Low pressure is not always obvious, especially with modern carbon fiber sidewalls and run-flat tires. The sides do not bulge out when underinflated like conventional tires. You must use a pressure gauge to verify inflation pressure with modern high-performance tire designs.

Tire Vibration Problems



Tire vibration is commonly caused by an out-of-balance condition, ply separation, excessive tire runout, a bent wheel, tire stiffness variation, or tire cupping. Refer to **Figure 74-5**.

When one of the *front* tires is vibrating, it can usually be felt in the *steering wheel*. When one of the *rear* tires is vibrating, the vibration will be felt in the *center* and *rear* of the car.

Tire and Wheel Bearing Noise

Tire noise usually shows up as a thumping sound caused by ply separation or as a whine due to abnormal tread wear. Inspect the tire for an out-of-round condition or tread cupping. Tire replacement is needed to correct these problems.

Wheel bearing noise is normally produced by a dry, worn, or damaged wheel bearing. The balls or rollers are damaged from lack of lubrication and are no longer smooth and round. The weight of the vehicle

Goodheart-Willcox Publisher

Figure 74-5. Four common causes of tire-related vibration. A—Wheel-tire assembly not balanced. B—Excessive tire runout. C—Bent rim or excessive rim runout. D—Stiffness variation in rubber.

Copyright Goodheart-Willcox Co., Inc.

pressing down on the chipped, pitted bearings causes them to emit a noticeable humming or growling sound.

Tech Tip

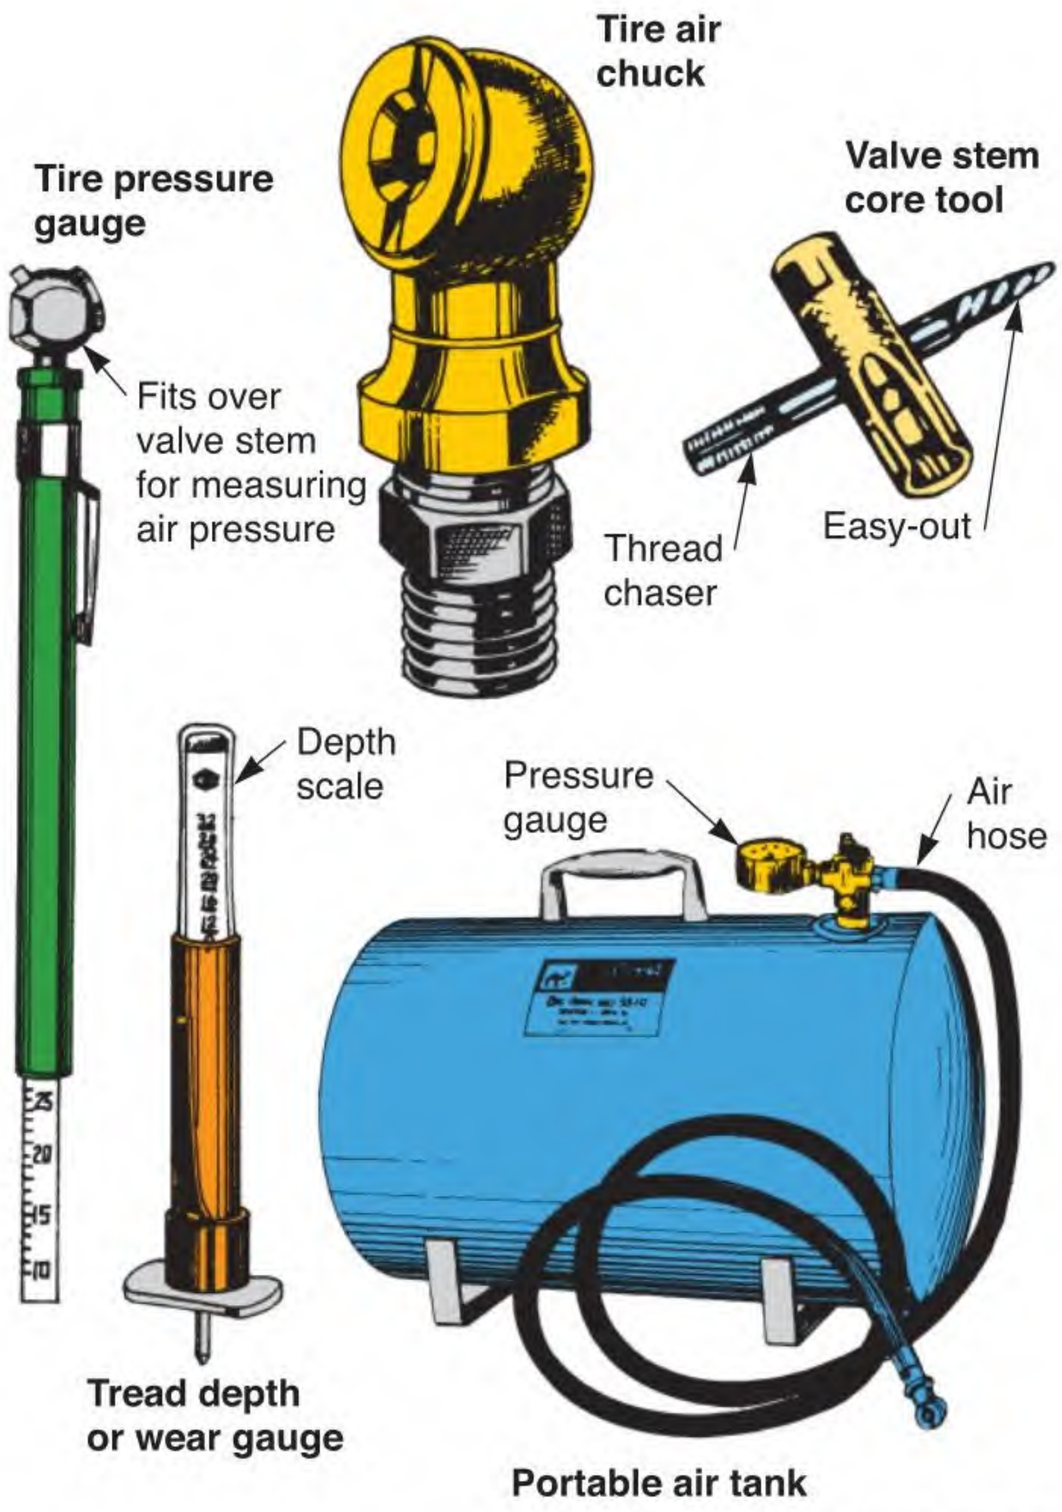
If overheated enough, wheel bearings can gall, glow red hot, and then seize together before bearing parts shatter. Total wheel bearing failure often causes the wheel and hub to fall off while cornering. This can be very dangerous to anyone near the self-destructing wheel bearing and out-of-control vehicle.

To check for a worn or loose wheel bearing, raise and secure the vehicle. Rotate the tire by hand while listening to it with a stethoscope. Feel and listen carefully for bearing roughness. Also, wiggle the tire back and forth to check for bearing looseness. You may have to disassemble the wheel bearing to verify the problem.

Wheel Cover and Cap Service

A ***wheel cover*** is the large metal or plastic decorative cover for the wheel. It is press-fit over the wheel rim to hide the lug nuts, dust cap, and other parts. Sometimes the lug nuts hold the plastic wheel cover in place. The plastic wheel cover will lift off easily once the lug nuts are removed.

To remove a barbed wheel cover, use the flat end of a lug wrench or a large screwdriver. Working carefully, pry between the wheel and cover at four alternating points. To install a barbed wheel cover, use a rubber hammer. Hold the wheel cover snugly in place with the valve stem aligned and sticking through the cover. Tap in a circular or alternating pattern.



A ***wheel cap*** is a small metal or plastic cover in the center of a wheel. It is commonly used on aluminum wheels to hide the spindle nut and cap. Like a wheel cover, it usually snaps into place in the center of the wheel.

Tire Maintenance

Tire maintenance involves periodic inspection, checking of inflation pressure, and rotation. These preventive maintenance steps will help ensure vehicle safety and longer tire life. **Figure 74-6** shows some of the tools used during tire maintenance and service procedures.

Periodic Inspection

Periodic tire inspection involves visually checking the condition of the tires. Look for anything that could affect the dependability of the tires—tread wear, cracks, cuts, tears, etc. Raise the vehicle on a lift so you can inspect the inside sidewalls and tread all the way around each tire. Most tire damage and normal wear is on the inner edge of the tread, which is impossible to see with the vehicle on the ground.

Camel; Snap-on

Checking Tire Inflation Pressure

Service Procedure

To measure tire inflation pressure:

1. Unscrew and remove the valve stem cap.
2. Press the ***tire pressure gauge*** squarely over the valve stem. See **Figure 74-7**. Use your fingers to hold the tool square as you push down to compress the valve core spring.
3. Read the air pressure indicated on the gauge.
4. Compare your reading to the recommended maximum tire pressure printed on the tire's sidewall or given by the vehicle manufacturer.
5. If the tire pressure is low, add air. If the pressure is high, press in on the valve core pin to release air from the tire.
6. Recheck tire pressure and add or release air as necessary.
7. Reinstall the valve stem cap snugly.

Most tire manufacturers recommend a cold inflation pressure that is 1 to 3 psi (21 kPa) below the maximum listed air pressure. This allows for tire heating, air expansion, and pressure increase without exceeding the maximum pressure limits.

Tech Tip

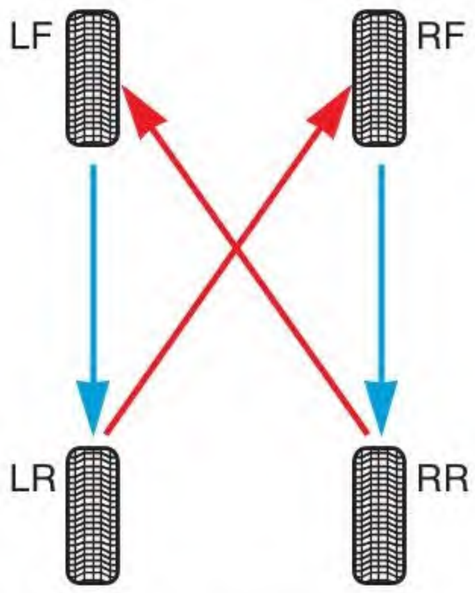
A ***tire load index number*** represents the weight (in pounds or kilograms) the tire can carry without failure. For example, a load index number of 91 means the tire can carry a maximum load of 1356 pounds (610 kilograms) at its highest rated speed. This index number, as well as the tire's load-carrying ability, is molded on the side of the tire for easy reference.

Rotating Tires

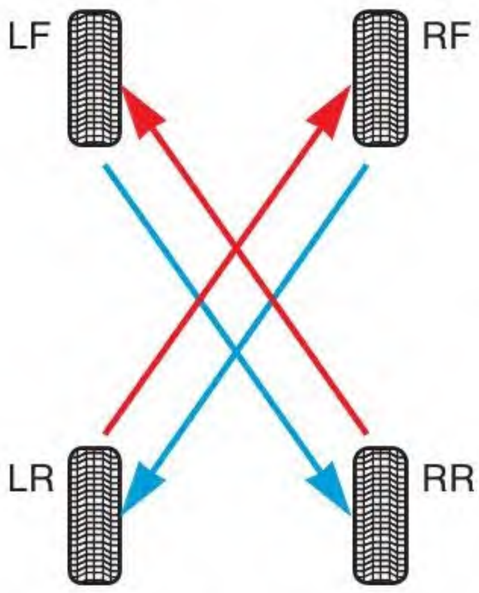
Tire rotation involves changing the location of the tires on the vehicle to ensure maximum tire life. Normally, the front or rear tires wear differently. Rotation helps even out tire wear and prevents premature failure of any one tire. For example, a front-wheel-drive car will wear out its front tires more quickly than its rear tires. On rear-wheel-drive vehicles, the rear tires will wear more quickly. Generally, tires should be rotated at intervals suggested by the tire manufacturer (typically every 3000 miles or 4827 km) or sooner, if irregular wear develops. See **Figure 74-8**.

Tech Tip

Many high performance cars come equipped with a different size tire on the front compared to the rear. Tire rotation is not practical with different size tires.



A B



Goodyear

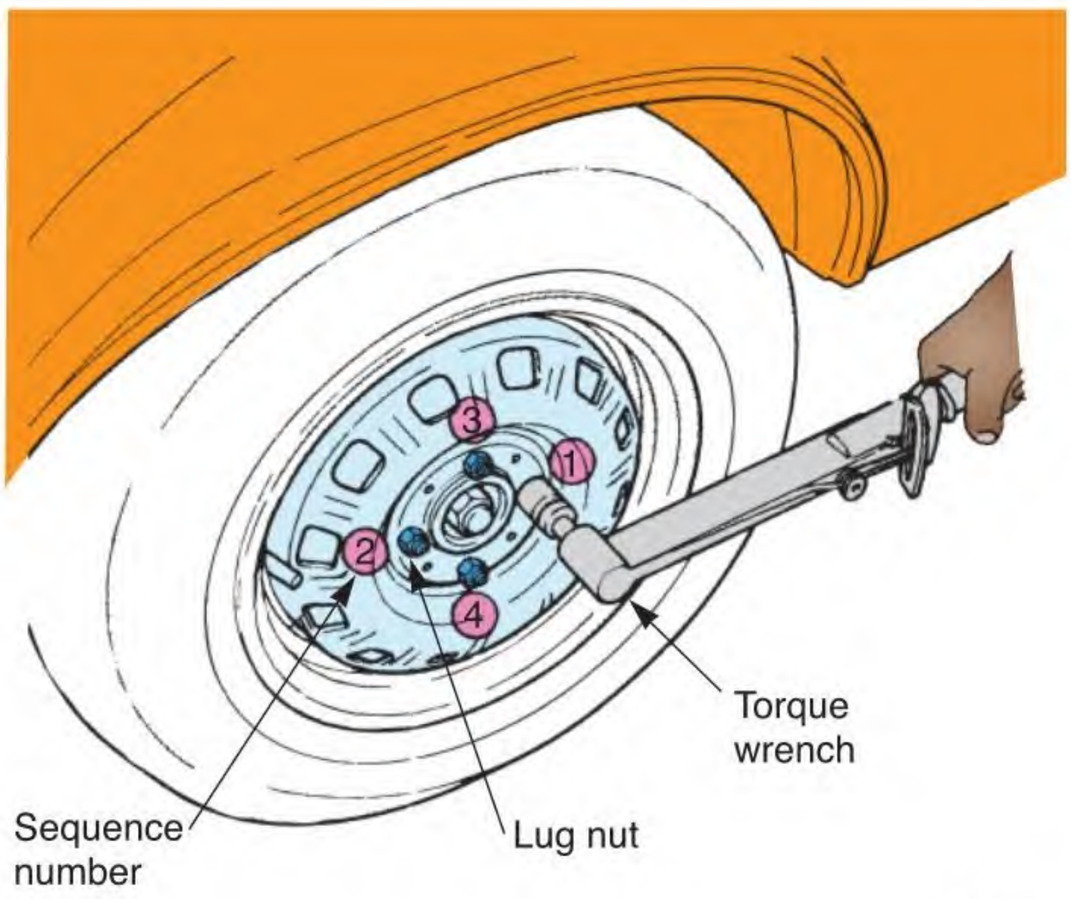
Figure 74-8. Study the typical tire recommendations for various vehicle and tire types.

Torquing Lug Nuts



Lug nut torque (tightening force) is very important, especially on vehicles equipped with mag wheels and lightweight hubs. Overtorquing can cause wheel or hub distortion, excessive runout, and vibration. Undertorquing might allow the lug nuts to loosen and the wheel to fall off.

Automakers suggest that lug nuts be tightened to specifications with a torque wrench. Tighten the nuts in a crisscross pattern as in **Figure 74-9**.

Replacing Lug Studs

Lug studs can become stripped or damaged. To replace them, force out the old stud with a special pressing tool or a hydraulic press. Do not use a hammer to drive the studs out because the hammer blows could damage the wheel bearing.

To install the new stud, use flat washers and a lug nut. You can usually draw the new stud into place by tightening the nut on the washers. Double-check that the stud is fully seated before installing the wheel.

Chrysler

Figure 74-9. Use a torque wrench to tighten lug nuts to specifications in crisscross pattern. Modern lightweight wheels and hubs require exact lug nut torque to avoid wheel warpage and damage.

Measuring Tire and Wheel Runout

Tire runout or wobble is caused by a faulty tire (ply separation or manufacturing defect). ***Wheel runout***, or wobble, is caused by impact damage or incorrect welding of the spider and rim. When you suspect a minor runout problem, use a dial indicator to measure tire and wheel runout.

Lateral runout is side-to-side movement. It is measured by placing a dial indicator against the side of the rim or on the tire sidewall. A special indicator with a small wheel or roller is commonly used to measure lateral runout. The technician turns the tire by hand while noting the indicator reading. See **Figure 74-10A**.

Radial runout is caused by a difference in radius from the center axis of rotation. It is measured by placing the dial indicator on the tire tread and on the inner part of the rim. Again, the tire is turned by hand and the indicator reading is noted. This is illustrated in **Figure 74-10B**.

Compare your dial indicator readings to specifications. If either lateral or radial runout is beyond specifications, replace the wheel or tire.

Chrysler

Figure 74-10. Using a dial indicator and a large base to measure tire and wheel runout (wobble). A—To measure lateral runout, mount the indicator on the tire sidewall and the side of rim. Rotate the tire and read the indicator. B—To measure radial runout, or out-of-round, mount the indicator on the tread and on the wheel inner lip as shown. Turn the tire by hand and read the indicator.

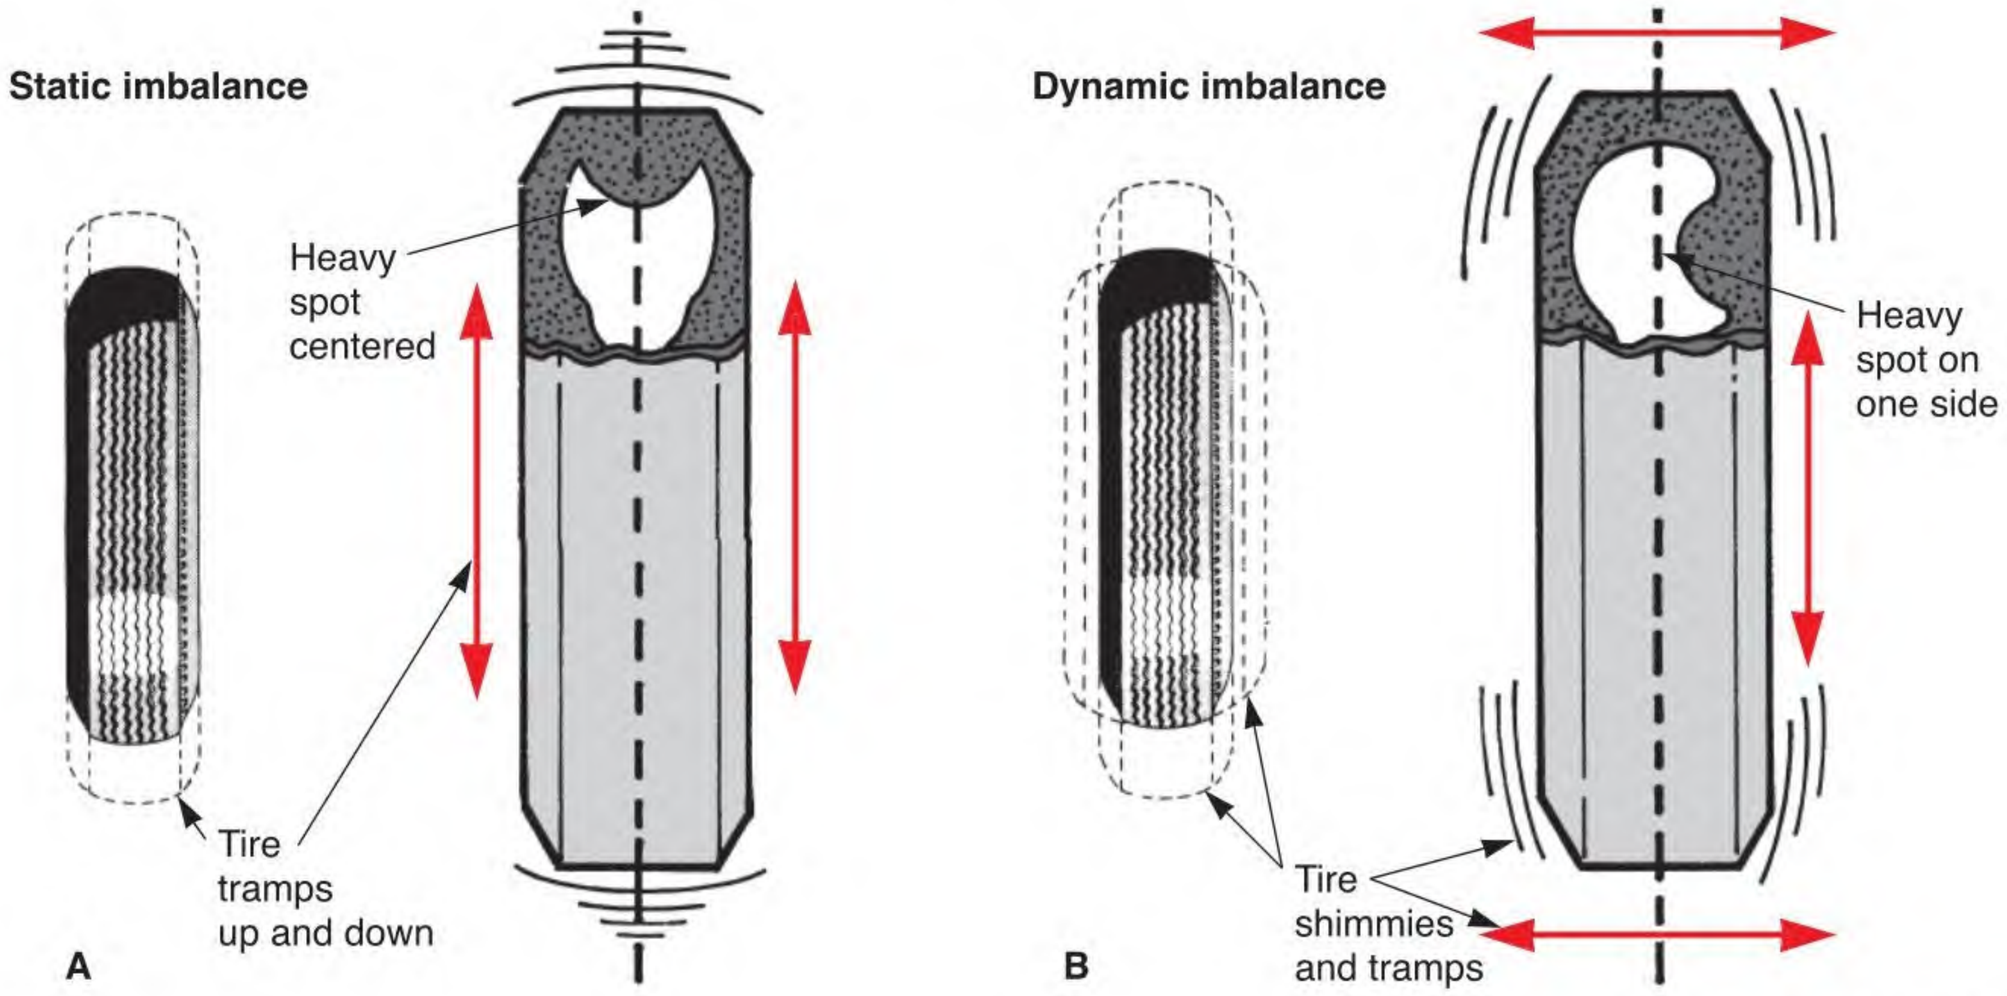
Sometimes, it is possible to reduce tire runout by rotating the tire 180° on the wheel. Typically, tire radial runout should *not* exceed 0.060″ (1.5 mm). Tire lateral runout should be under 0.090″ (2.0 mm). Wheel radial runout should *not* be over 0.035″ (0.9 mm). Wheel lateral runout should *not* exceed 0.045″ (1.0 mm). However, always refer to exact specifications before condemning a wheel or tire.

Wheel Balance

Improper wheel balance is one of the most common causes of tire and steering wheel vibration. When one side of the tire is heavier than the other, centrifugal force tries to throw the heavy side outward when the tire is spinning. There are two types of tire imbalance: static imbalance and dynamic imbalance.

Static imbalance, called *wheel tramp* or *hop*, causes the tire to vibrate up and down. For a wheel and tire assembly to be in static balance, its weight must be evenly distributed around the axis of rotation. See **Figure 74-11A**.

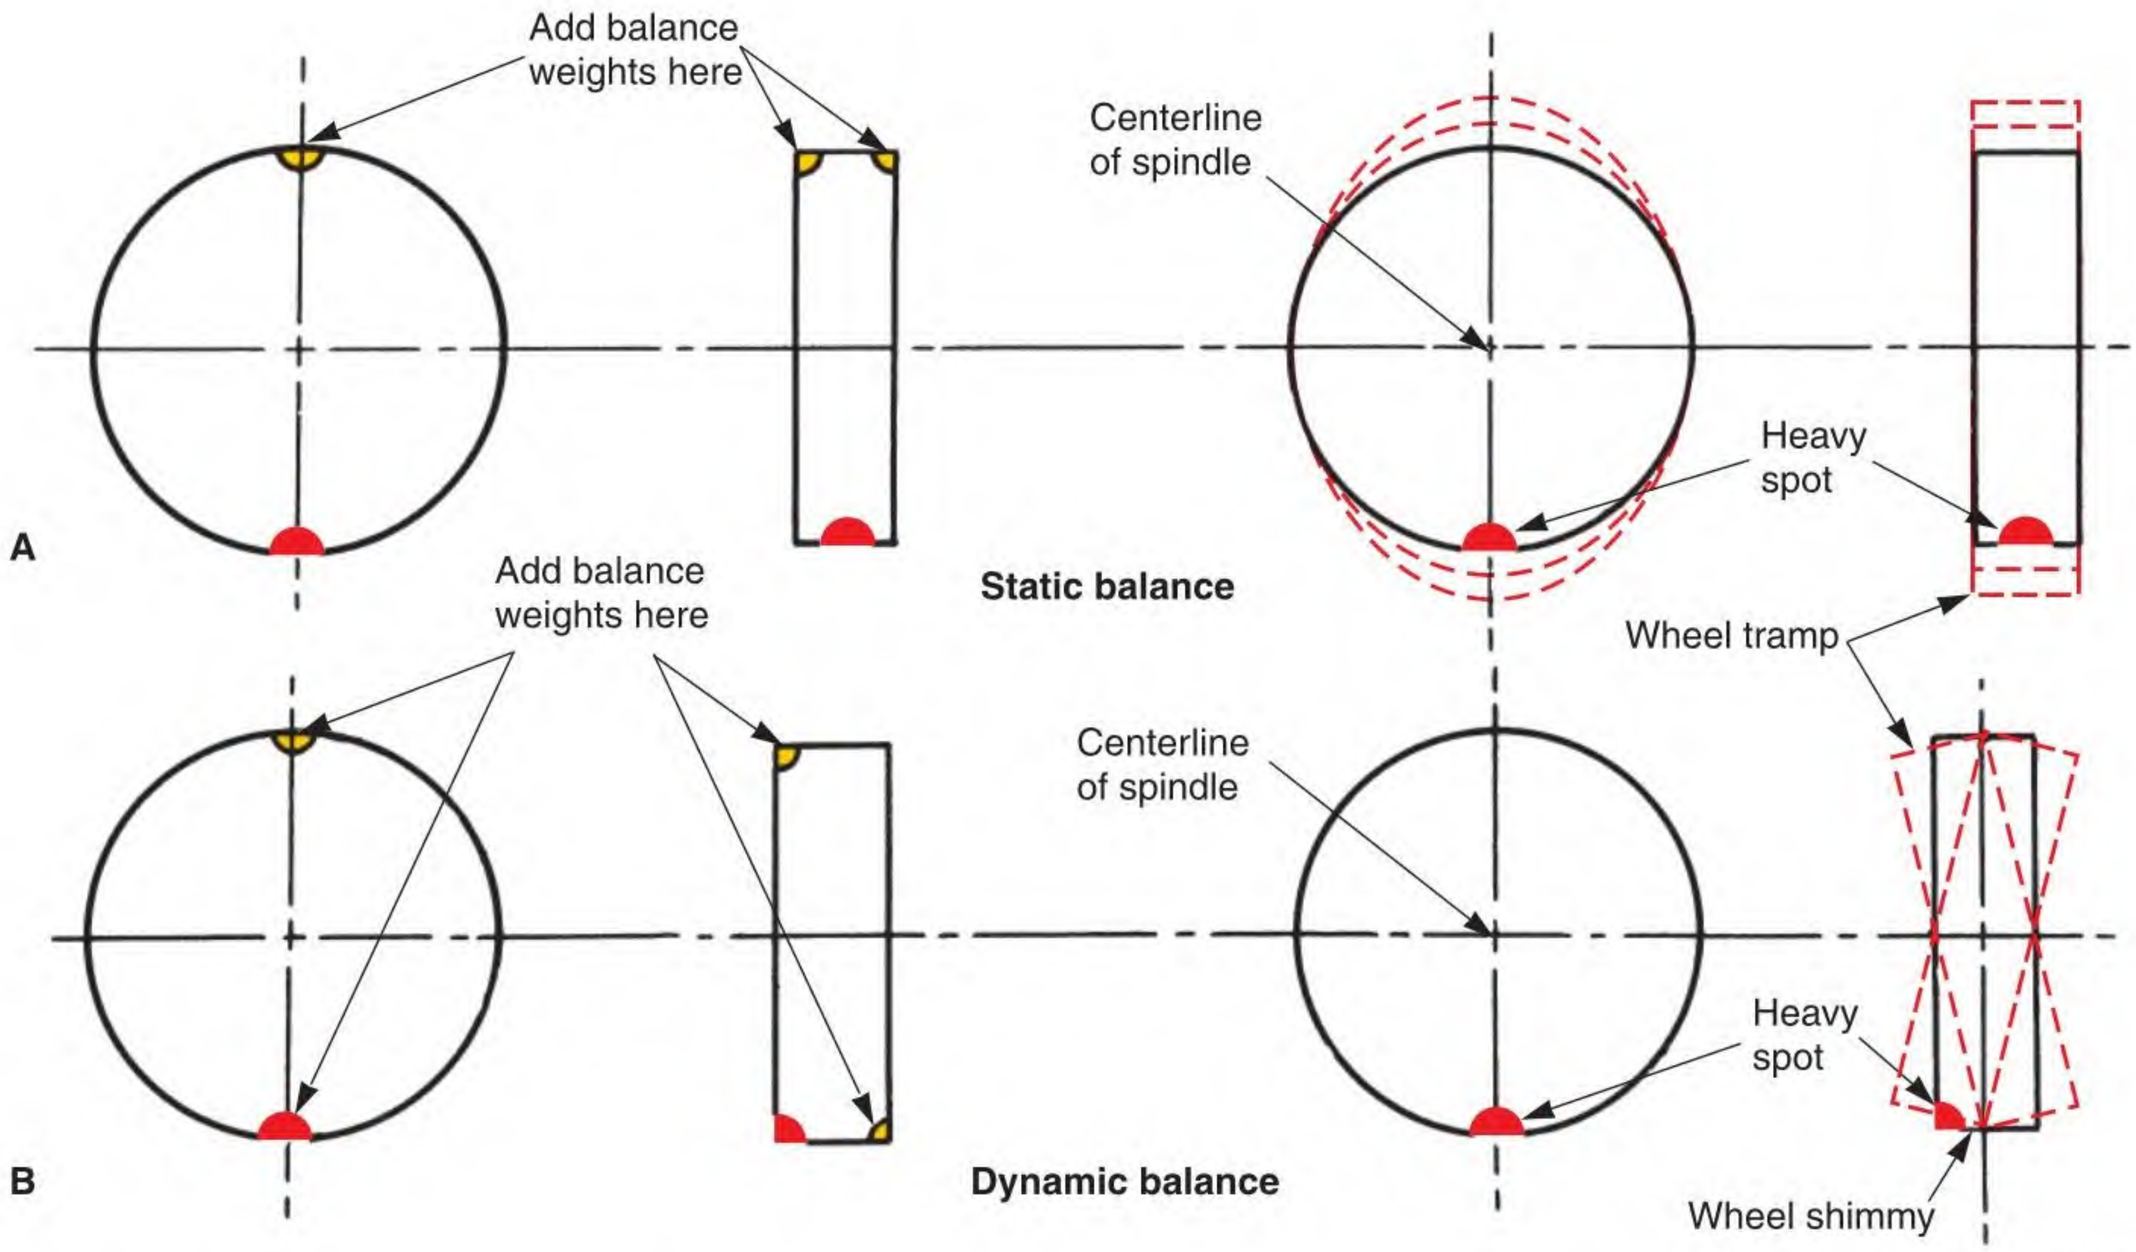
Dynamic imbalance causes both ***wheel hop*** (up-and-down movement) and ***wheel shimmy*** (side-to-side movement). To be in dynamic balance, the top-to-bottom weight and side-to-side weight must all be equal, **Figure 74-11B**.



When *not* in dynamic balance (one side heavier than the other), centrifugal force tries to throw the heavy area outward. As a result, the tire and wheel assembly is pushed one way (thrown downward and toward center) and then the other way (thrown upward and away from center).

Wheel Balancing

Wheel balancing involves adding ***wheel weights*** (special lead weights that clip or stick on the rim) to the side opposite the heavy area found on the wheel/tire assembly. Lead wheel weights for steel wheels often clip over the edge of the rim. Special aluminum wheel weights have a wider opening and can be hammered in place on thicker aluminum wheels. Lead weights for soft aluminum wheels have an adhesive backing to adhere the weight onto the inner wheel drop center area.



To static balance a wheel and tire assembly, add wheel weights opposite the heavy area of the wheel. If a large amount of weight is needed, add half to the inside of the wheel and the other half to the outside of the wheel. This helps keep dynamic balance correct. Look at **Figure 74-12A**.

Copyright Goodheart-Willcox Co., Inc.

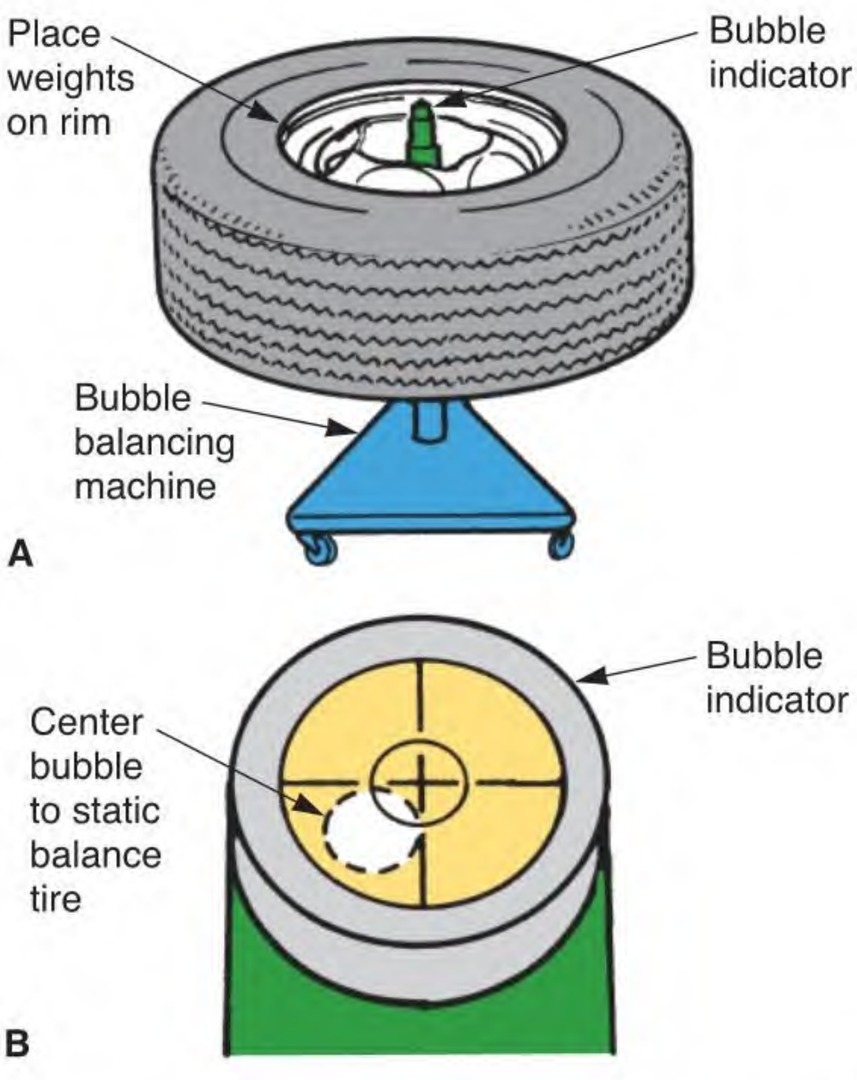
Goodheart-Willcox Publisher

Figure 74-11. Static and dynamic imbalance are common causes of vibration. A—Static imbalance will cause tire to vibrate up and down. It is caused by a heavy spot located in the center of the tire tread. B—Dynamic imbalance will make tire vibrate from side to side and up and down. The heavy spot on tire is to one side of the tread or on sidewall.

Goodheart-Willcox Publisher

Figure 74-12. Note the basic procedure for correcting static and dynamic imbalance. A—Static imbalance will cause wheel tramp. Add weight opposite the heavy area on both sides of the wheel. Each weight should be half as heavy as the heavy spot on the tire. B—Dynamic imbalance will cause wheel shimmy. Add weight in two locations to counteract the heavy area.

Copyright Goodheart-Willcox Co., Inc.



To dynamically balance a wheel and tire, you must add weights exactly where needed, **Figure 74-12B**. The dynamic balancing machine will indicate where and how much weight to add to bring the assembly into dynamic balance.

When balancing a wheel assembly, follow these safety rules:

- Wear eye protection when spinning the wheel and tire assembly.
- Remove rocks and other debris from tire tread before balancing the wheel assembly.
- Follow the operating instructions provided with the wheel balancing equipment. Machine designs vary and so do operating procedures.

Wheel Balancing Machines

A ***wheel balancing machine*** is used to determine which area of a wheel/tire assembly is heavy. A ***bubble balancer*** will static balance a wheel and tire assembly. The wheel and tire assembly must be removed from the car and placed on the balancer. An indicating bubble on the machine is then used to locate the heavy area of the assembly. Wheel weights are added to the wheel until the bubble is *centered* on the crosshairs of the machine. See **Figure 74-13**.

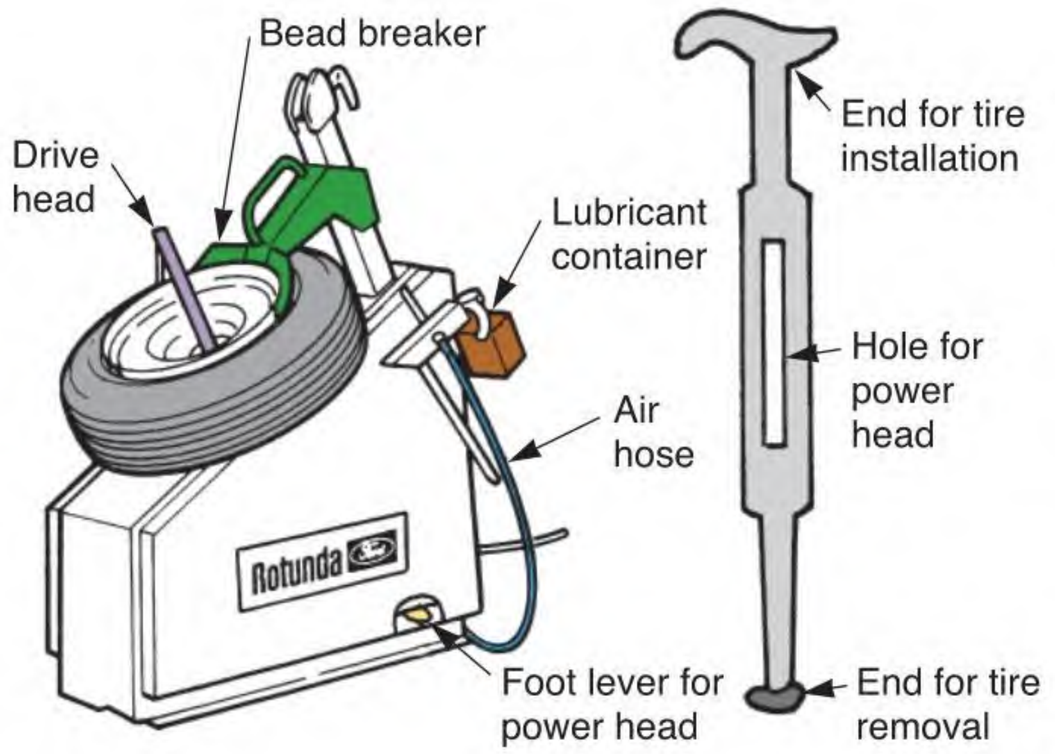
Ammco

Figure 74-13. A bubble balancer will correct static imbalance only. A—The tire is mounted on a bubble balancer as shown. B—Use balancer instructions to place weights on the wheel until the bubble centers in the circle on the balancer head.

An ***off-car balancer*** can either be a static- or dynamic-type machine. The wheel and tire assembly is mounted on the balancer and spun. The machine will detect vibration of the assembly and indicate where wheel weights should be added on a monitor screen. See **Figure 74-14**. After adding weights, spin the tire again to check for vibration. When perfectly balanced, the balancing machine will indicate zero weight is needed.

Mounting and Dismounting Tires

When mounting or dismounting a tire on its wheel, ***tire changing machine***, often called a ***tire changer***, is used to force the rubber tire on and off the metal wheel. One type of tire changer is illustrated in **Figure 74-15**.



The pneumatic ***bead breaker*** is used first to force the tire bead away from the wheel rim, **Figure 74-16**. The bead beaker arms should be positioned to contact the tire

Hunter Engineering Co.

Figure 74-14. This wheel balancer applies the pressure of a steel roller to the tire tread when spinning and balancing the wheel/tire assembly. A roller spins with the tire to measure run-out and to more closely emulate driving conditions. The computer screen indicates where to add stick-on wheel weights.

Ford

Figure 74-15. Modern tire changers use air pressure to force the tire on and off the wheel. Follow all safety rules provided with the equipment. The bar is mounted on the power head. The head turns the bar to force the beads over the rim.

bead and not the wheel. Then, a special bar is attached to the machine's drive head. The head turns the bar, which pries the bead over and off the rim. The other end of the bar is used when installing the tire on the wheel.

A few rules to follow when mounting or dismounting tires include:

- Wear eye protection and remove the valve core before breaking the bead away from the wheel.
- Keep your fingers out of the way when removing a tire from a wheel.
- Never mount a tire on a rim that is *not* smooth and clean.
- Always lubricate the tire bead and wheel flange with proper lubricant (vegetable oil-soap solution) before mounting a tire. *Never* use antifreeze, motor oil, or any other nondrying petroleum-based substance as a lubricant. Tire deterioration or movement on the wheel may result.
- Use care when mounting or dismounting tires on wheels equipped with air pressure sensors. Improper procedures may damage these sensors.

A B

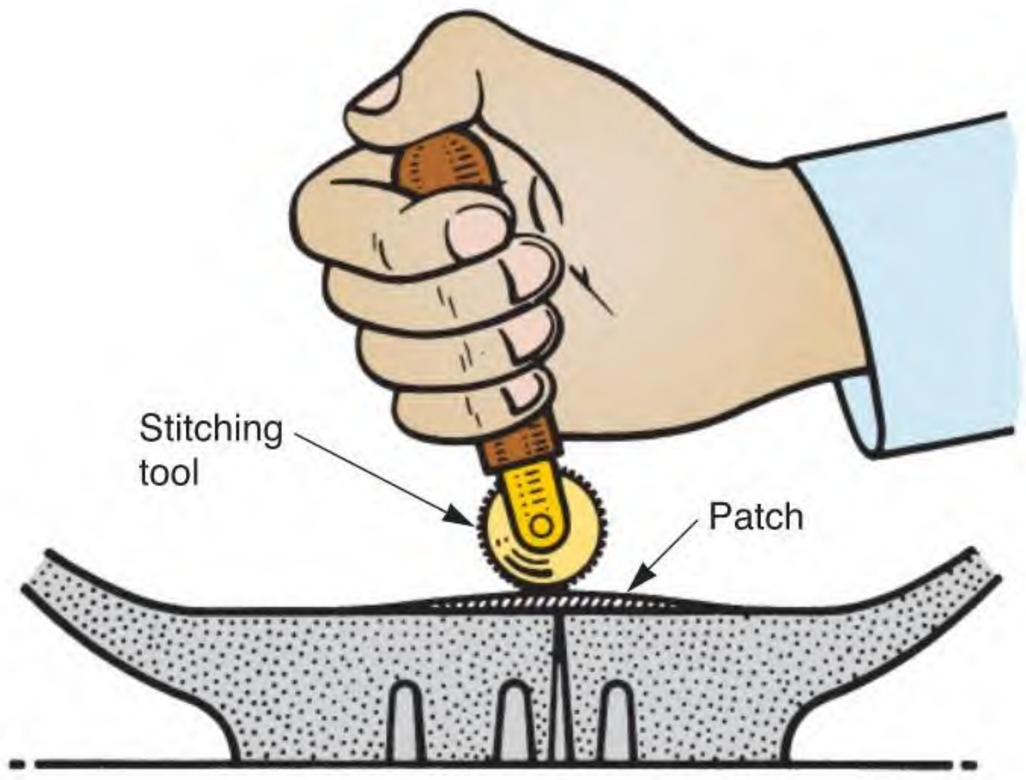
Hunter Engineering Co.

Figure 74-16. Always follow operating instructions for the specific make and model of the tire changer. A—Tire changers exert tremendous force to stretch tire beads on and off the wheel. Use care. B—Automated tire changers greatly simplify equipment operation. Make sure you read operating instructions for the particular unit before use.

Copyright Goodheart-Willcox Co., Inc.

- Do *not* inflate a tire when it is lying on the floor. When the beads seat, the tire could fly dangerously into the air.
- Stand away from the tire when adding air after mounting. Usually, a loud "pop" sound will be made when the beads seat.
- Do *not* exceed 40–50 psi (276–345 kPa) when initially inflating a tire to seat its bead on the wheel.
- After initial inflation, install the core and inflate the tire to the recommended pressure.

Some modern, automated tire changers use a rubber wheel or plastic covered arm to force the bead back over the wheel. This protects wheels from paint damage or scuffing of the finish.



Tire Puncture Repair

To find a leak, fill the tire with air. Then, place the tire in a drum full of water or wet the tire with soapy water in a spray bottle. Look for air bubbles forming on the tire. Bubbles indicate a leak. Mark the leak with a crayon or chalk.

Service Procedure

To properly repair a small tire puncture:

1. Remove the tire from the rim.
2. After dismounting the tire, *inspect* the inside surface carefully to locate the puncture and to determine the nature and extent of the damage.
3. Fill the injury to the tire using a recommended plug or liquid sealant.
4. Select a patch that extends well beyond the damaged area, so that it will adhere properly to the inner liner and withstand the heat and mechanical stresses of tire use.
5. Scuff (roughen) the area that the patch will cover, so that it will adhere tightly.
6. Apply the proper cement (adhesive) to the inner liner, following the repair kit directions.
7. Remove the covering from the adhesive side of the patch and carefully place the patch on the inner liner.
8. Use a stitcher tool to tightly bond the patch to the inner liner. See **Figure 74-17**.

Goodheart-Willcox Publisher

Figure 74-17. Patch on inside of tire is needed for all repairs. Basically, scuff the area around the injury. Apply a coat of approved cement. Remove the cover from the patch and apply the patch over the damage. Use a stitcher to adhere the patch to the tire liner.

The following are a few basic rules for tubeless tire repair:

- Do *not* attempt to repair a puncture by plugging it from the outside of the tire. *Always* dismount the tire and patch the inner liner.
- Never attempt to repair sidewalls or tires with punctures larger than 1/2″ (13 mm) in diameter.
- When removing an object from the tire, reduce air pressure to 15 psi (103 kPa) or less.
- Broken strands in steel belted tires may indicate serious damage. Also, the broken strands could puncture the patch or plug, causing a serious tire failure.
- Follow the exact procedures given with the tire repair kit.

Tech Tip

Do not perform a quick tire repair by simply inserting a rubber or rope plug into the hole in the tire. According to the Rubber Manufacturer's Association (RMA), using a plug to attempt a tire repair without dismounting is effective only 80% of the time. The remaining 20% will result in tire failure, which may take the form of a dangerous sudden deflation. RMA lists two requirements for correct puncture repair: the damage to the tire must be filled and the inner liner must be soundly patched.

Copyright Goodheart-Willcox Co., Inc.

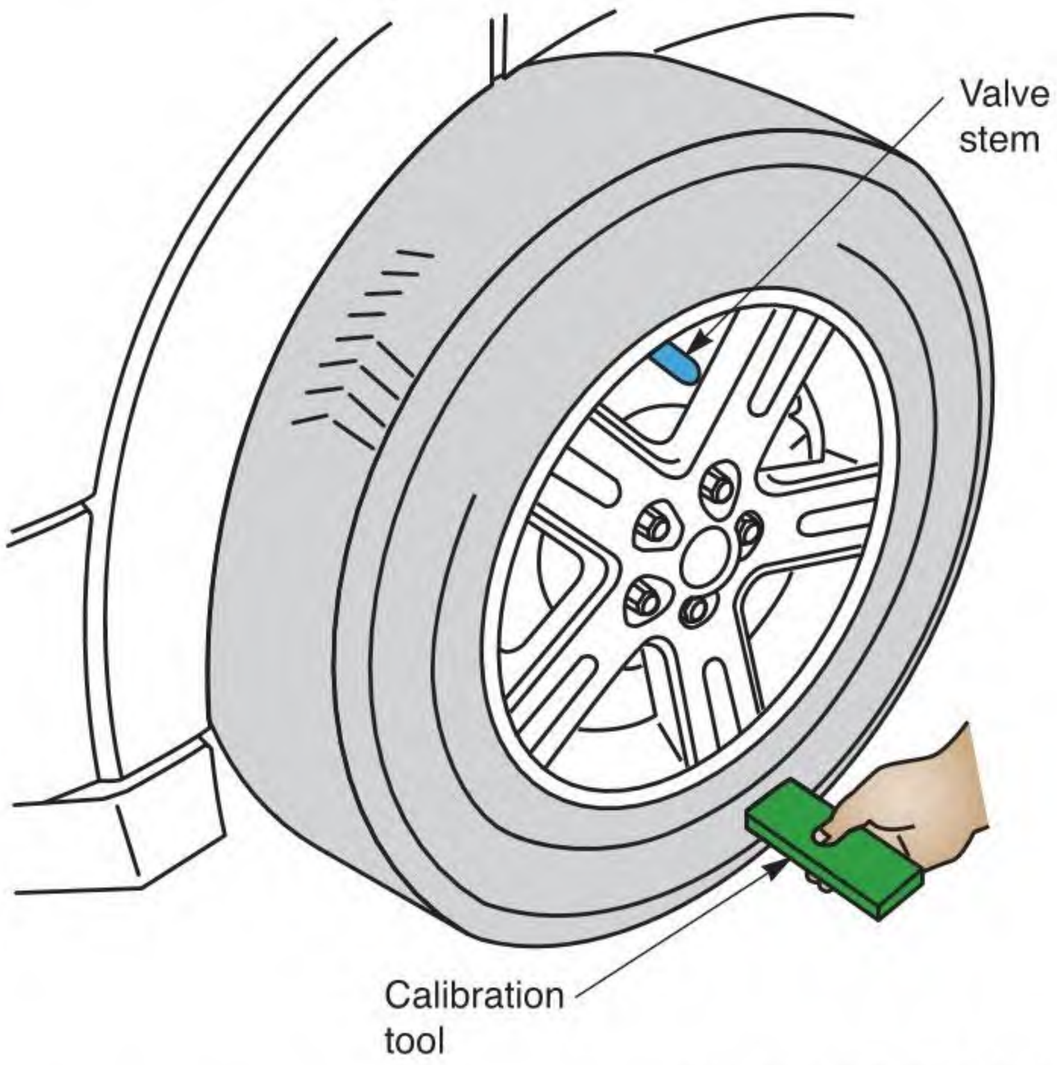
Tire Pressure Monitoring System Service

There are two types of tire pressure monitoring systems: direct systems and indirect systems.

A direct tire pressure monitoring system uses pressure sensor mounted inside each tire to monitor tire pressure and report low-pressure conditions to a receiver in the passenger compartment. Each pressure sensor is capable of generating a weak electromagnetic radio wave, and the output frequency represents tire air pressure. The ECM has its own antenna tuned to this frequency for interpreting the radio signals coming from the four tire pressure sensors. Direct tire pressure monitoring sensors may or may not contain a small battery.

An ***indirect tire pressure monitoring*** system relies on the anti-lock brake system wheel speed sensors to monitor wheel rotational speeds and tire pressure. A tire with very low air pressure has a smaller effective diameter or circumference. The vehicle's wheel spindle is also closer to the ground. The smaller-diameter, deflated tire rotates a little faster than the fully-inflated, larger-diameter tires.

If a tire in a direct system has low air pressure but the system does not activate, suspect the tire pressure sensors. These sensors are battery operated and the batteries can become drained after a long period of service. In most cases, a sensor must be replaced when its battery becomes discharged. If the sensors are working properly, the problem may be in the receiver, the warning light, or the wiring between the receiver and the warning light.



Tech Tip

Many manufacturers recommend that the battery-powered tire pressure sensors be replaced whenever the tires are replaced. Battery life for these sensors is typically 5–6 years.

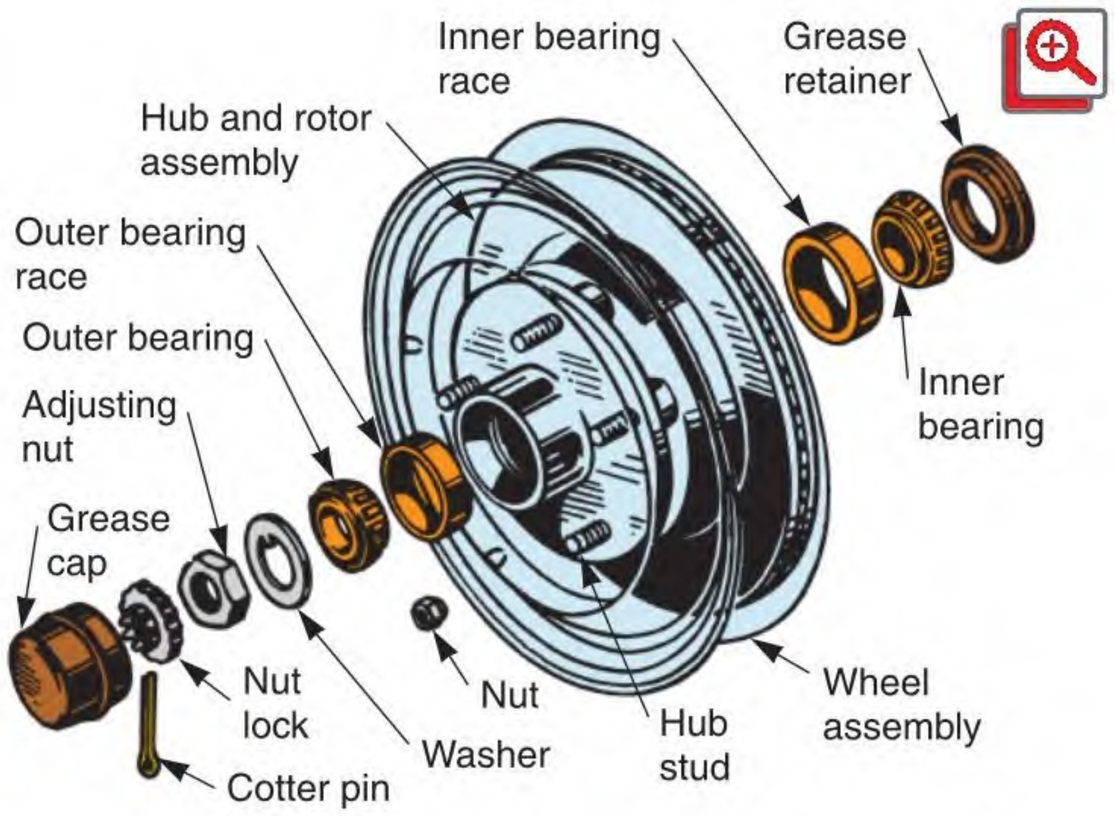
Care must be taken when removing the tire from a wheel equipped with a pressure sensor. Since the pressure sensor and ring are inside the wheel, do not hit the sensor with the bead breaker bar tool. Position the breaker bar near the valve stem to avoid contact with the sensor. When removing the tire from a wheel equipped with a stem-mounted sensor, position the valve stem 180° from the bead breaker on the tire machine to prevent sensor damage.

When installing a new drop center-mounted sensor, position new sensor 180° from the valve stem. When installing a valve-mounted sensor, use new stem seals and torque the stem retaining nut to specifications to prevent leaks and damage to the sensor. After pressure sensor replacement, be careful not to damage the sensor when reinstalling the tire on the wheel. Most sensors will begin transmitting a signal within two minutes after you inject normal air pressure into the tire.

After a sensor is replaced or a vehicle's tires are rotated, the sensors must be calibrated using a dedicated calibration tool so the receiver recognizes which sensor is at which wheel. To calibrate a sensor, inflate the tires to the correct air pressure. Then, aim the calibration tool at the sensor inside the tire and press the calibration button on the tool, **Figure 74-18**. This will force the sensor to transmit a signal. There is generally a specific sequence that you must follow when calibrating the pressure sensors. For example, you might have to begin at the left front tire, then move to the right front, the right rear, and finally the left rear. Follow the instrument instructions to program the vehicle ECM to read accurately. The frequency produced by the sensor should be programmed to read the exact air pressure you installed in the tire earlier.

Goodheart-Willcox Publisher

Figure 74-18. A calibration tool is needed to calibrate a tire pressure sensor. After inflating the tire to the recommended pressure, hold the tool near the sensor and then press the button on the tool to calibrate the sensor. This particular tire has a sensor located in the drop center of the wheel, 180° from the valve stem.



Copyright Goodheart-Willcox Co., Inc.

Problems in indirect tire pressure monitoring systems are often caused by faulty wheel speed sensors. Malfunctions in indirect systems generally also cause anti-lock brake system malfunctions. In most cases, these systems can be diagnosed using a scan tool and standard anti-lock brake system troubleshooting procedures.

Wheel Bearing Service

Wheel bearings are normally filled with grease. If this grease dries out, the bearing will fail. It is wise to check wheel bearings for wear when performing wheel- or tire-related service. Some wheel bearings can be disassembled and packed (filled) with grease. Others are sealed units that require replacement when worn.

As you will learn, service methods for vehicles with rear-wheel drive are quite different than those for vehicles with front-wheel drive.

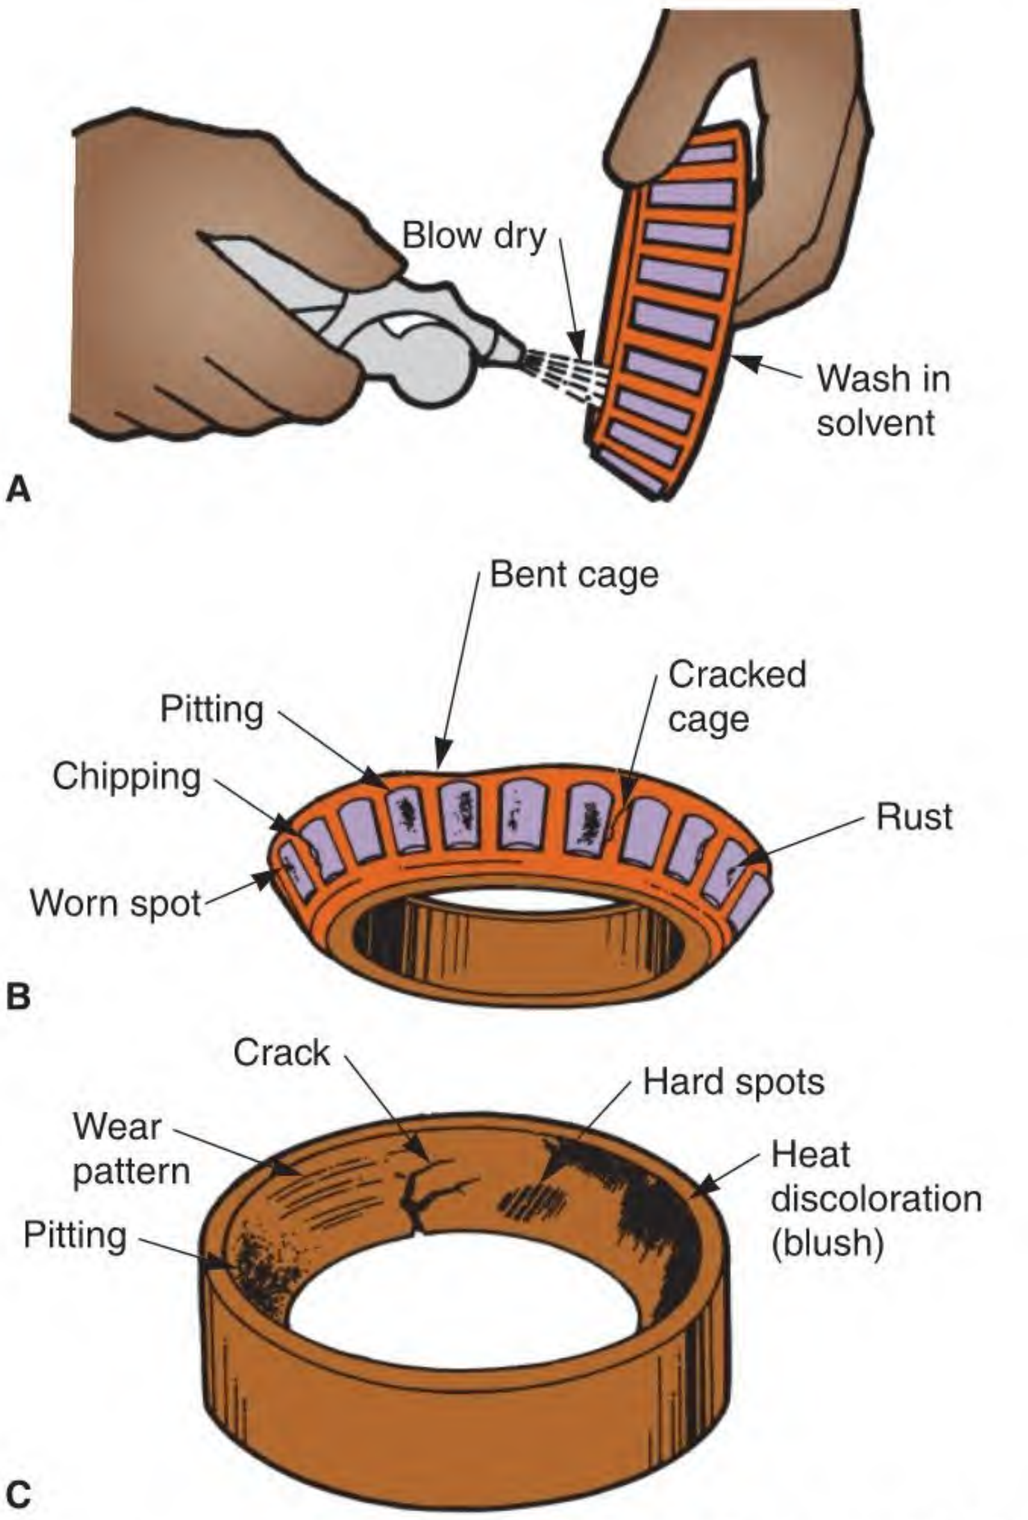
Ford

Figure 74-19. Servicing a nondriving hub and tapered roller wheel bearing assembly involves cleaning, inspection, lubrication, and adjustment. Study how parts fit together.

Tech Tip

If, during your test-drive, you hear the hum of a bad wheel bearing, there is an easy way to verify your diagnosis. Raise the car on a lift and rotate the tire and bearing while touching the suspension spring with your other hand. Spring oscillations will amplify the rough, dry bearing so that you can feel the vibration more easily. A stethoscope held on the knuckle will also allow you to hear the rough, dry bearing noise.

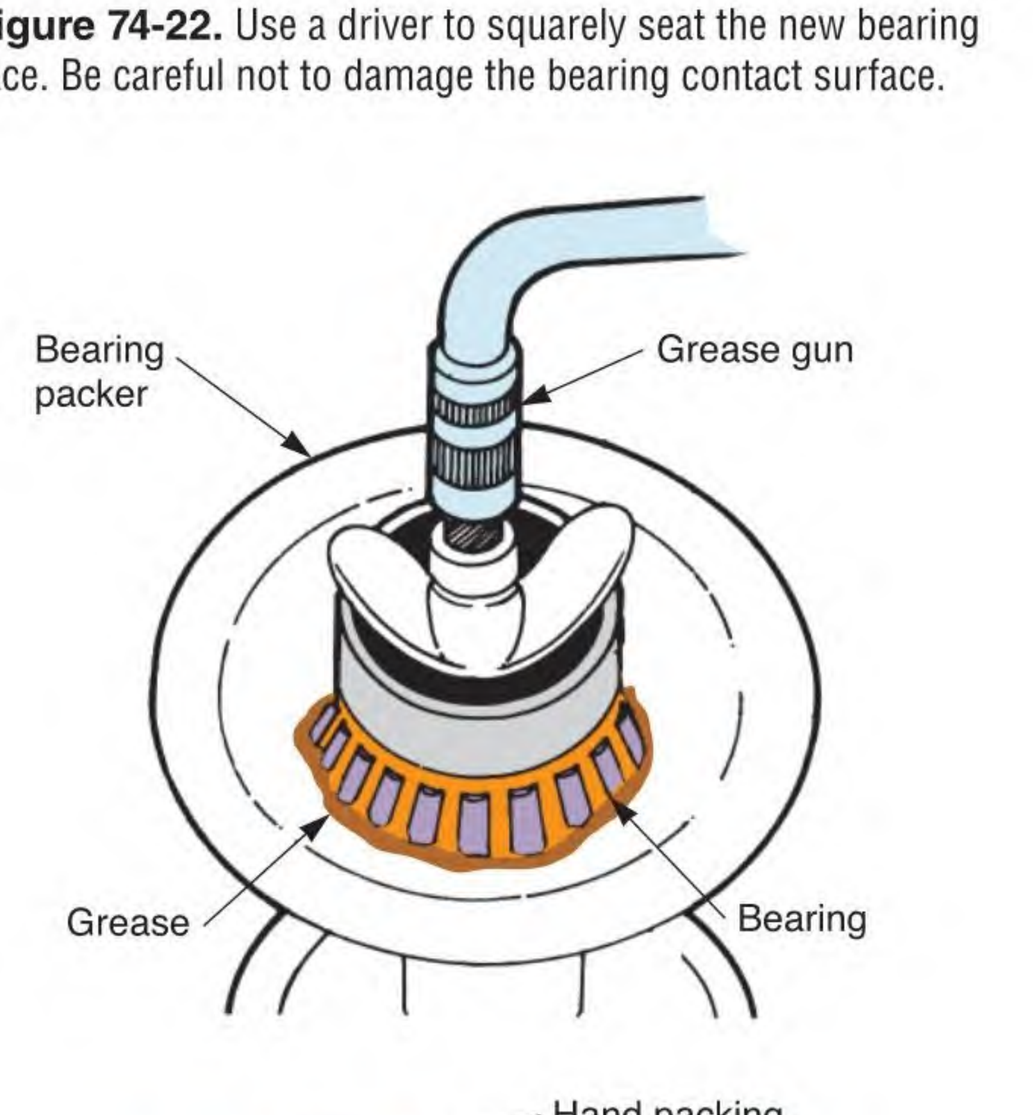
Servicing Wheel Bearings (Tapered Roller Bearings)



An exploded view of a typical nondriving tapered roller wheel bearing assembly is shown in **Figure 74-19**.

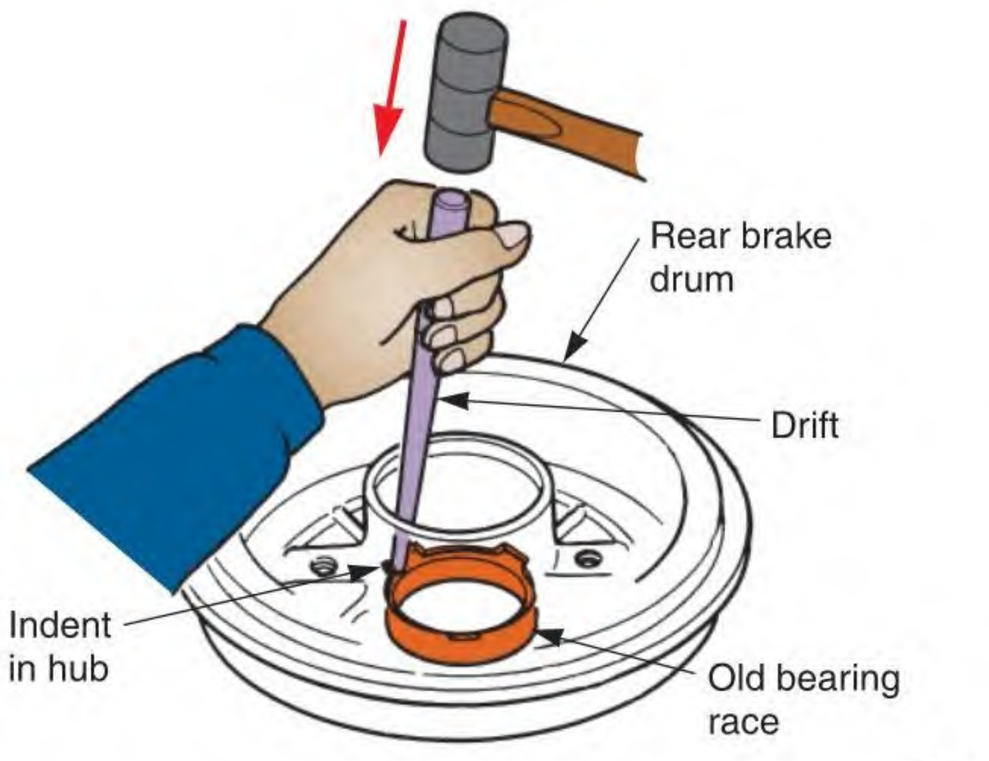
Service Procedure

To disassemble tapered roller bearings:



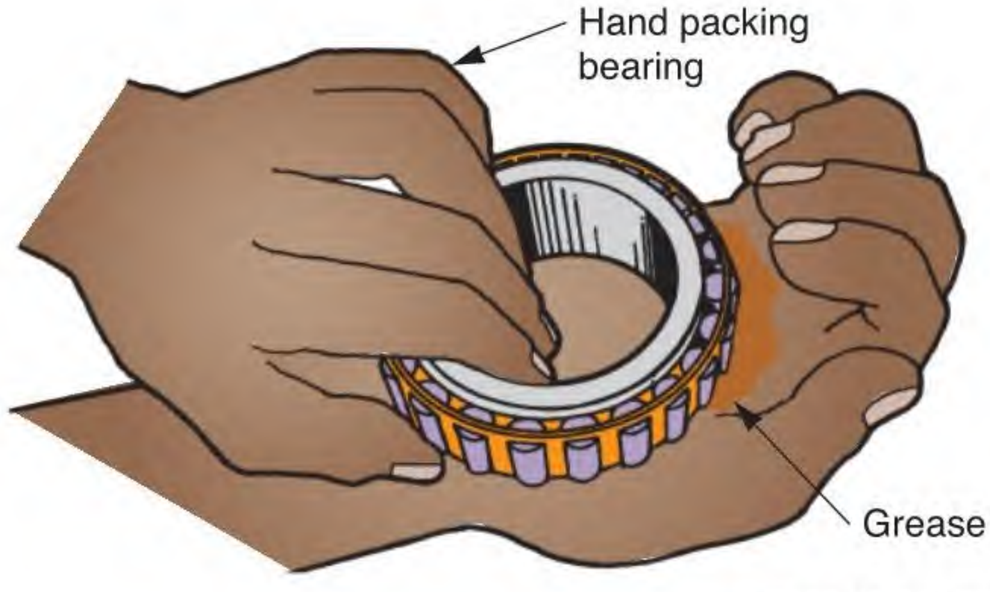
1. Partially loosen the lug nuts.
2. Raise the vehicle and secure it on jack stands.
3. Remove the wheel, grease cap, cotter pin, nut lock, adjusting nut, and safety washer.
4. Wiggle the hub and pull out the outer wheel bearing.
5. Screw the adjusting nut back onto the spindle.
6. Unbolt the brake caliper and secure it to one side, if needed.
7. Slide the hub outward on the spindle. When the inner bearing catches on the adjusting nut, the grease seal and the inner wheel bearing will pop out.
8. Wipe the bearings and races clean.
9. Keep the bearings in *order*, because they must be reinstalled in the same races.
10. Closely inspect the bearings and races for damage. If problems are found, you must replace both the bearing and race as a *set*. See **Figure 74-20**.
11. To replace a bearing race, drive out the old race with a large drift punch and hammer, **Figure 74-21**. Be careful not to damage the hub.
12. To install the new race, use a driving tool, as shown in **Figure 74-22**.
13. Wipe out all the old grease from the inside of the hub.
14. Partially fill the cavity with new wheel-bearing grease. Use the recommended type of grease. High-temperature wheel-bearing grease is recommended in most cases.
15. To pack the bearings, use your hands or a ***bearing packer*** (device for filling bearing cage with grease) to properly lubricate the bearing assemblies. Make sure grease is worked completely through each bearing cage and around every ball or roller, **Figure 74-23**.

Copyright Goodheart-Willcox Co., Inc.



Florida Dept. of Voc. Ed.

Figure 74-20. Clean bearings and races before inspecting for wear and damage. A—Wash and dry bearings. Do not let bearings spin while blowing them dry. B and C—Inspect the bearing and race for these kinds of troubles.



Honda

Figure 74-22. Use a driver to squarely seat the new bearing race. Be careful not to damage the bearing contact surface.

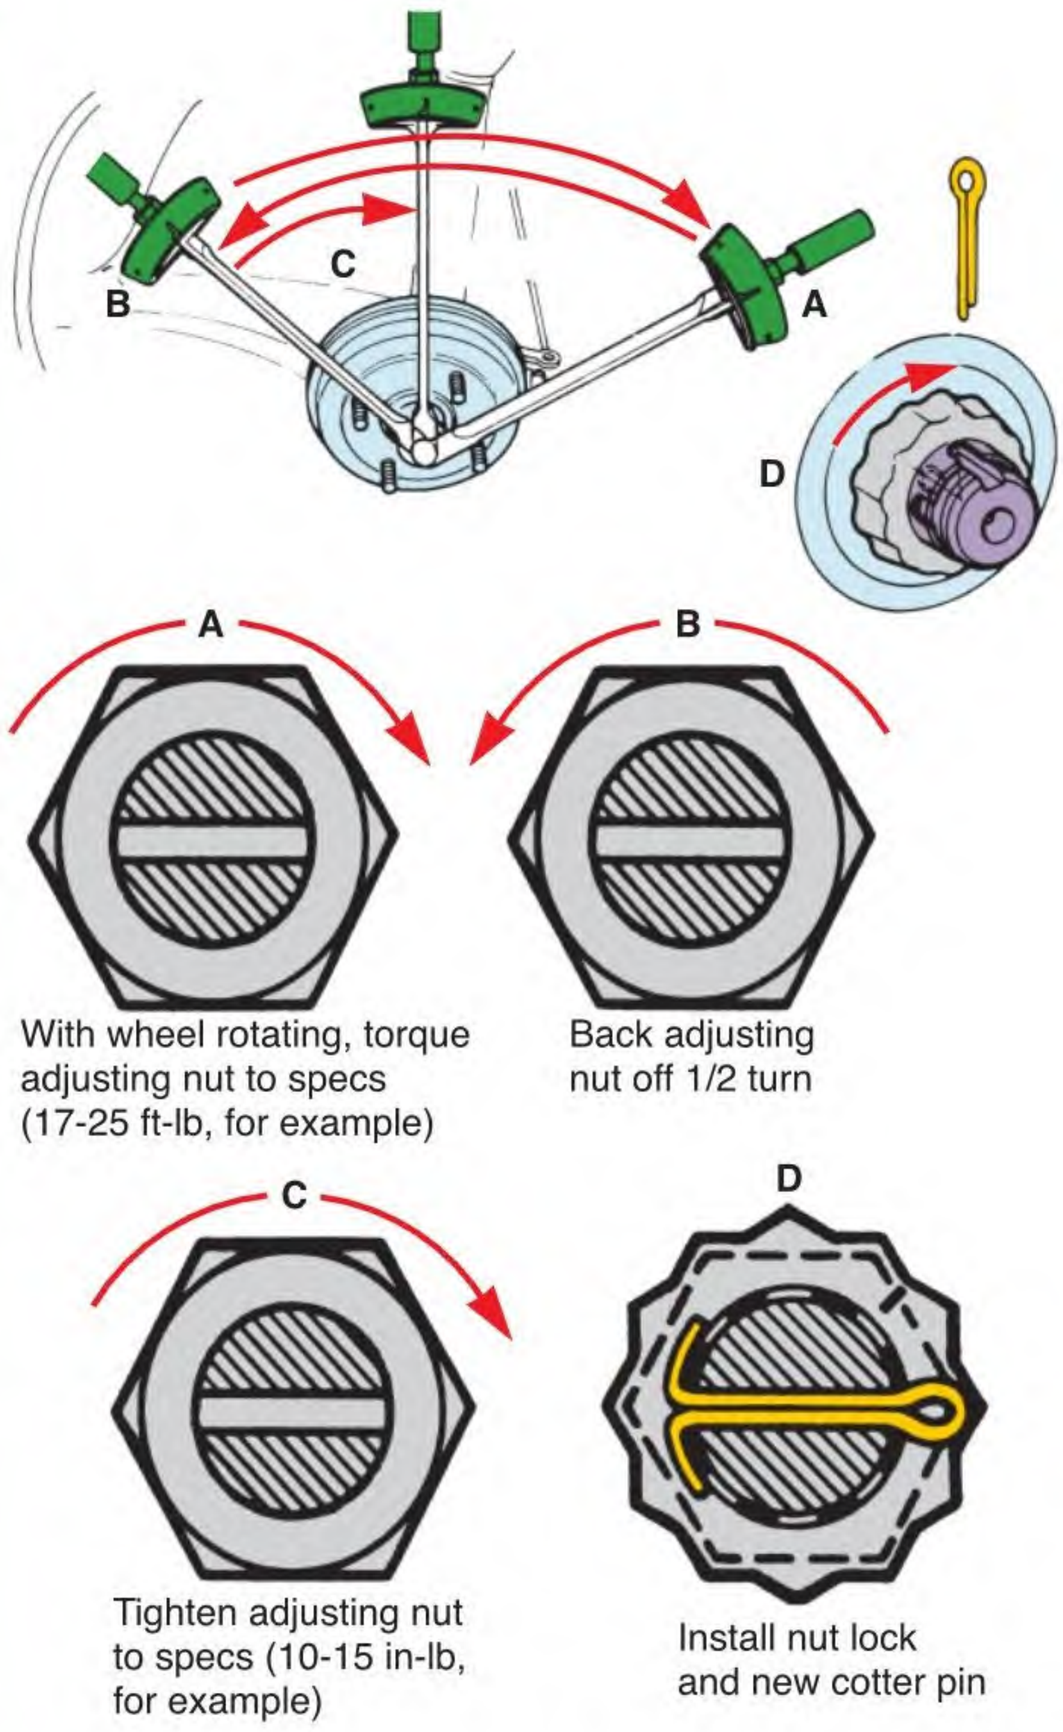
Honda

Figure 74-21. If a bearing is bad, the race will also be damaged and must also be replaced. Use a flat-nose drift to force the old race out of the hub.

Florida Dept. of Voc. Ed.

Figure 74-23. Pack bearings with quality, high-temperature wheel-bearing grease. Use either a bearing packer or the palm of your hand to work grease into cage and around rollers.

Copyright Goodheart-Willcox Co., Inc.



Caution

Do not use all-purpose wheel-bearing grease in wheel bearings on cars with disc brakes. The heat generated by the brakes can liquefy the grease and cause leakage out of the grease seals.

16. Place the inner bearing into its race.
17. Using a seal driver, install the new grease seal in the hub. If a seal driver is not available, drive the seal into the hub with light taps from a hammer. Tap in a circular pattern around the seal. Make sure you do not dent the seal.
18. Wipe the spindle clean.
19. Slide the hub into position and install the outer bearing.
20. Fit the safety washer against the bearing and screw on the adjusting nut.
21. Tighten the adjusting nut as described in a service manual. One manual gives the procedures presented in **Figure 74-24**.
22. Install the nut lock.
23. Install and bend the new cotter pin. This is very important because it keeps the adjusting nut, bearings, hub, and front wheel from falling off.
24. Force the dust cap back into the hub to protect the bearings from road dirt or water.

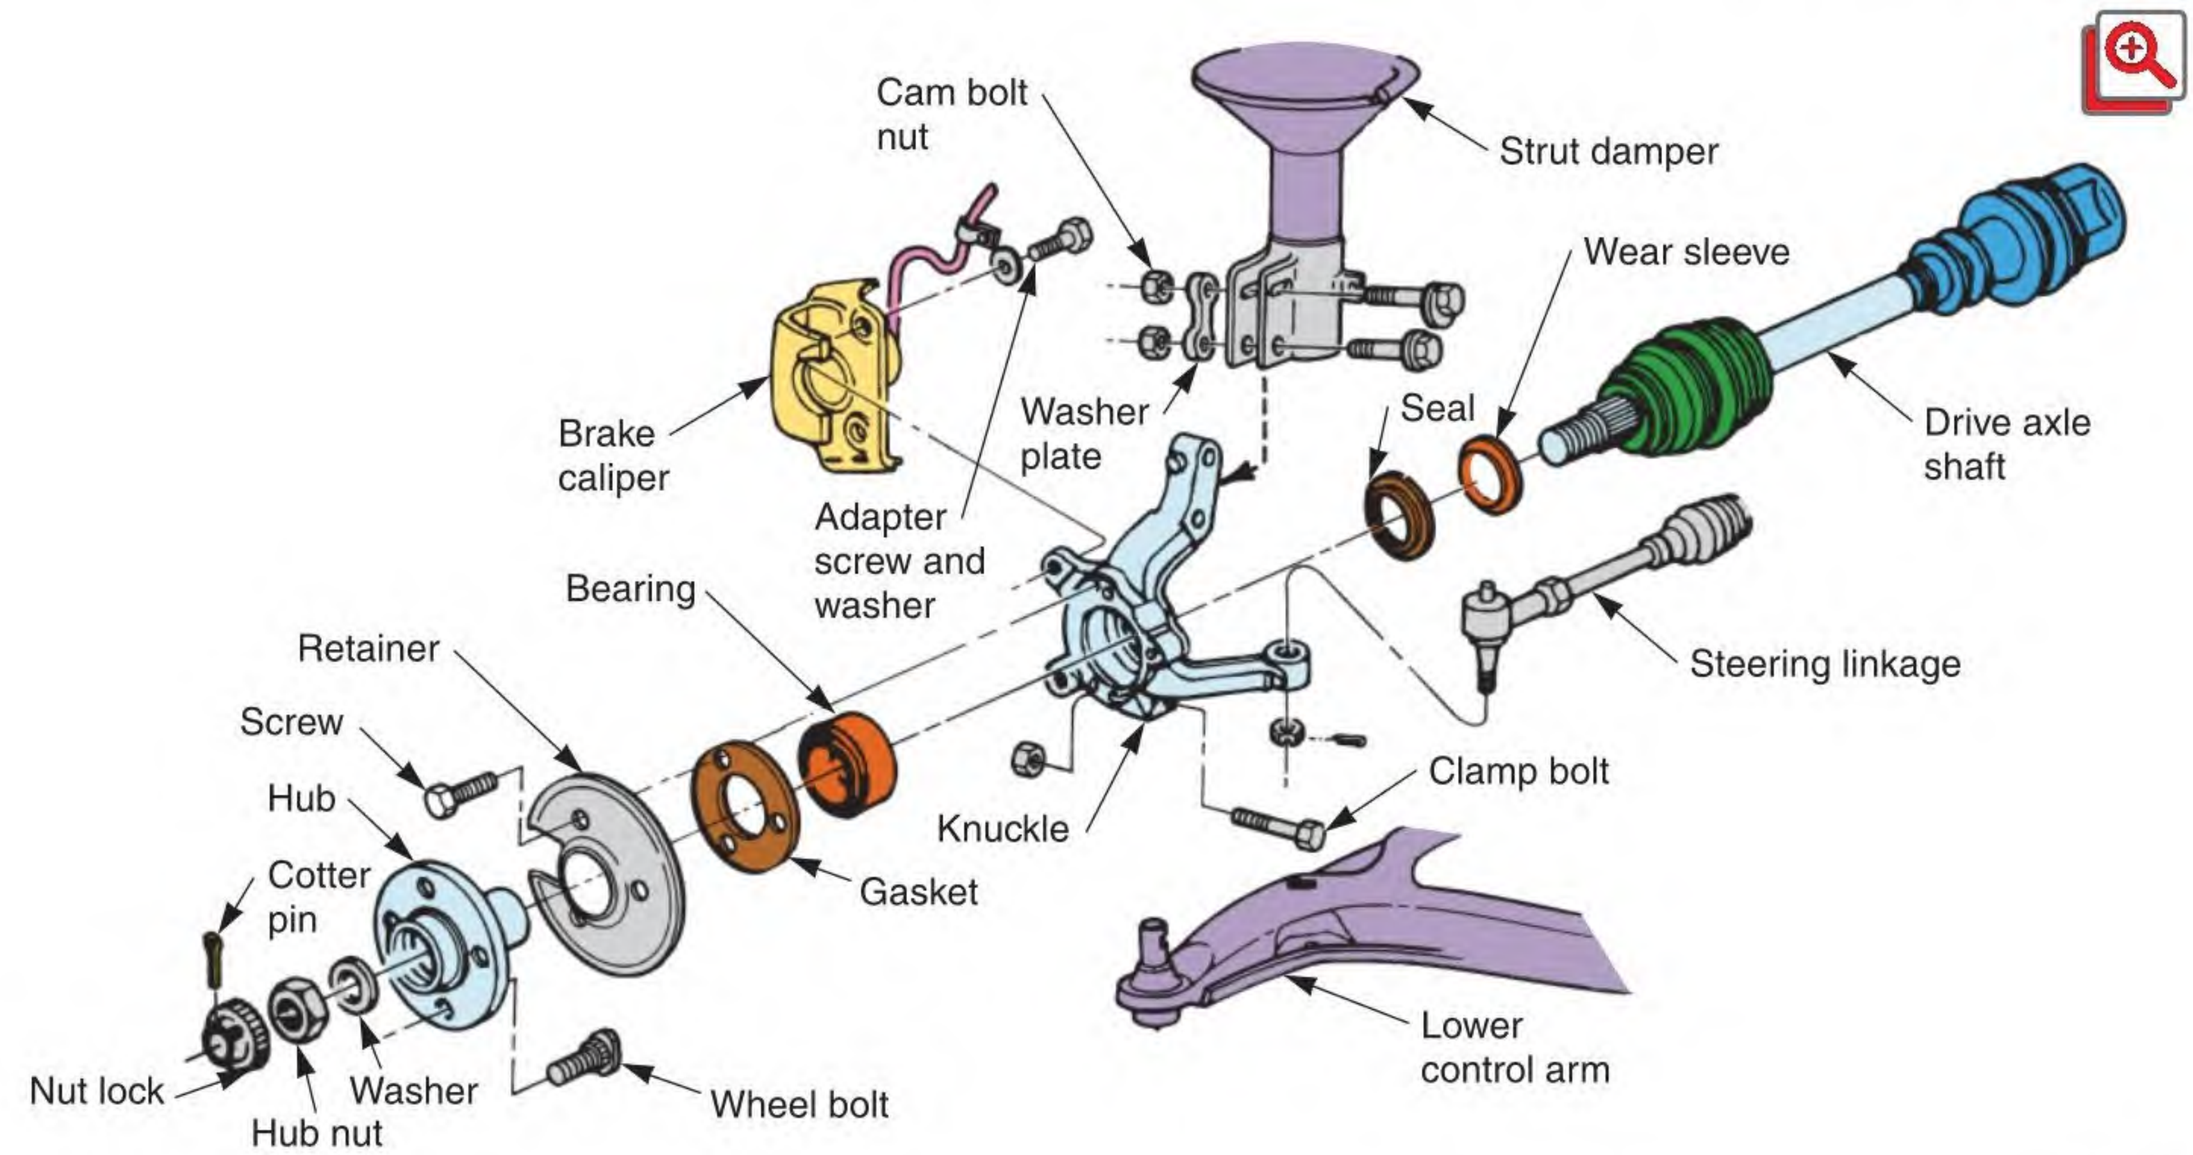
Caution

Keep grease off the brake disc or drum when servicing the wheel bearings. The slightest amount of grease could ruin the brake pads or shoes or cause squeaking.

Honda; Ford

Figure 74-24. Typical procedure for tightening the adjusting nut on a nondriving wheel bearing assembly. A—Torque the nut to specifications to seat the bearings. Rotate the hub. B—Back off the adjusting nut one-half turn. C—Tighten the adjusting nut to specs (about one foot-pound or less). D—Install a new cotter pin.

Servicing Wheel Bearings (Ball or Straight Roller Bearings)



Ball or straight roller wheel bearing assemblies are normally not serviced unless specified or when major repairs are needed. **Figure 74-25** shows an exploded view of a typical driving hub and wheel bearing assembly.

Service Procedure

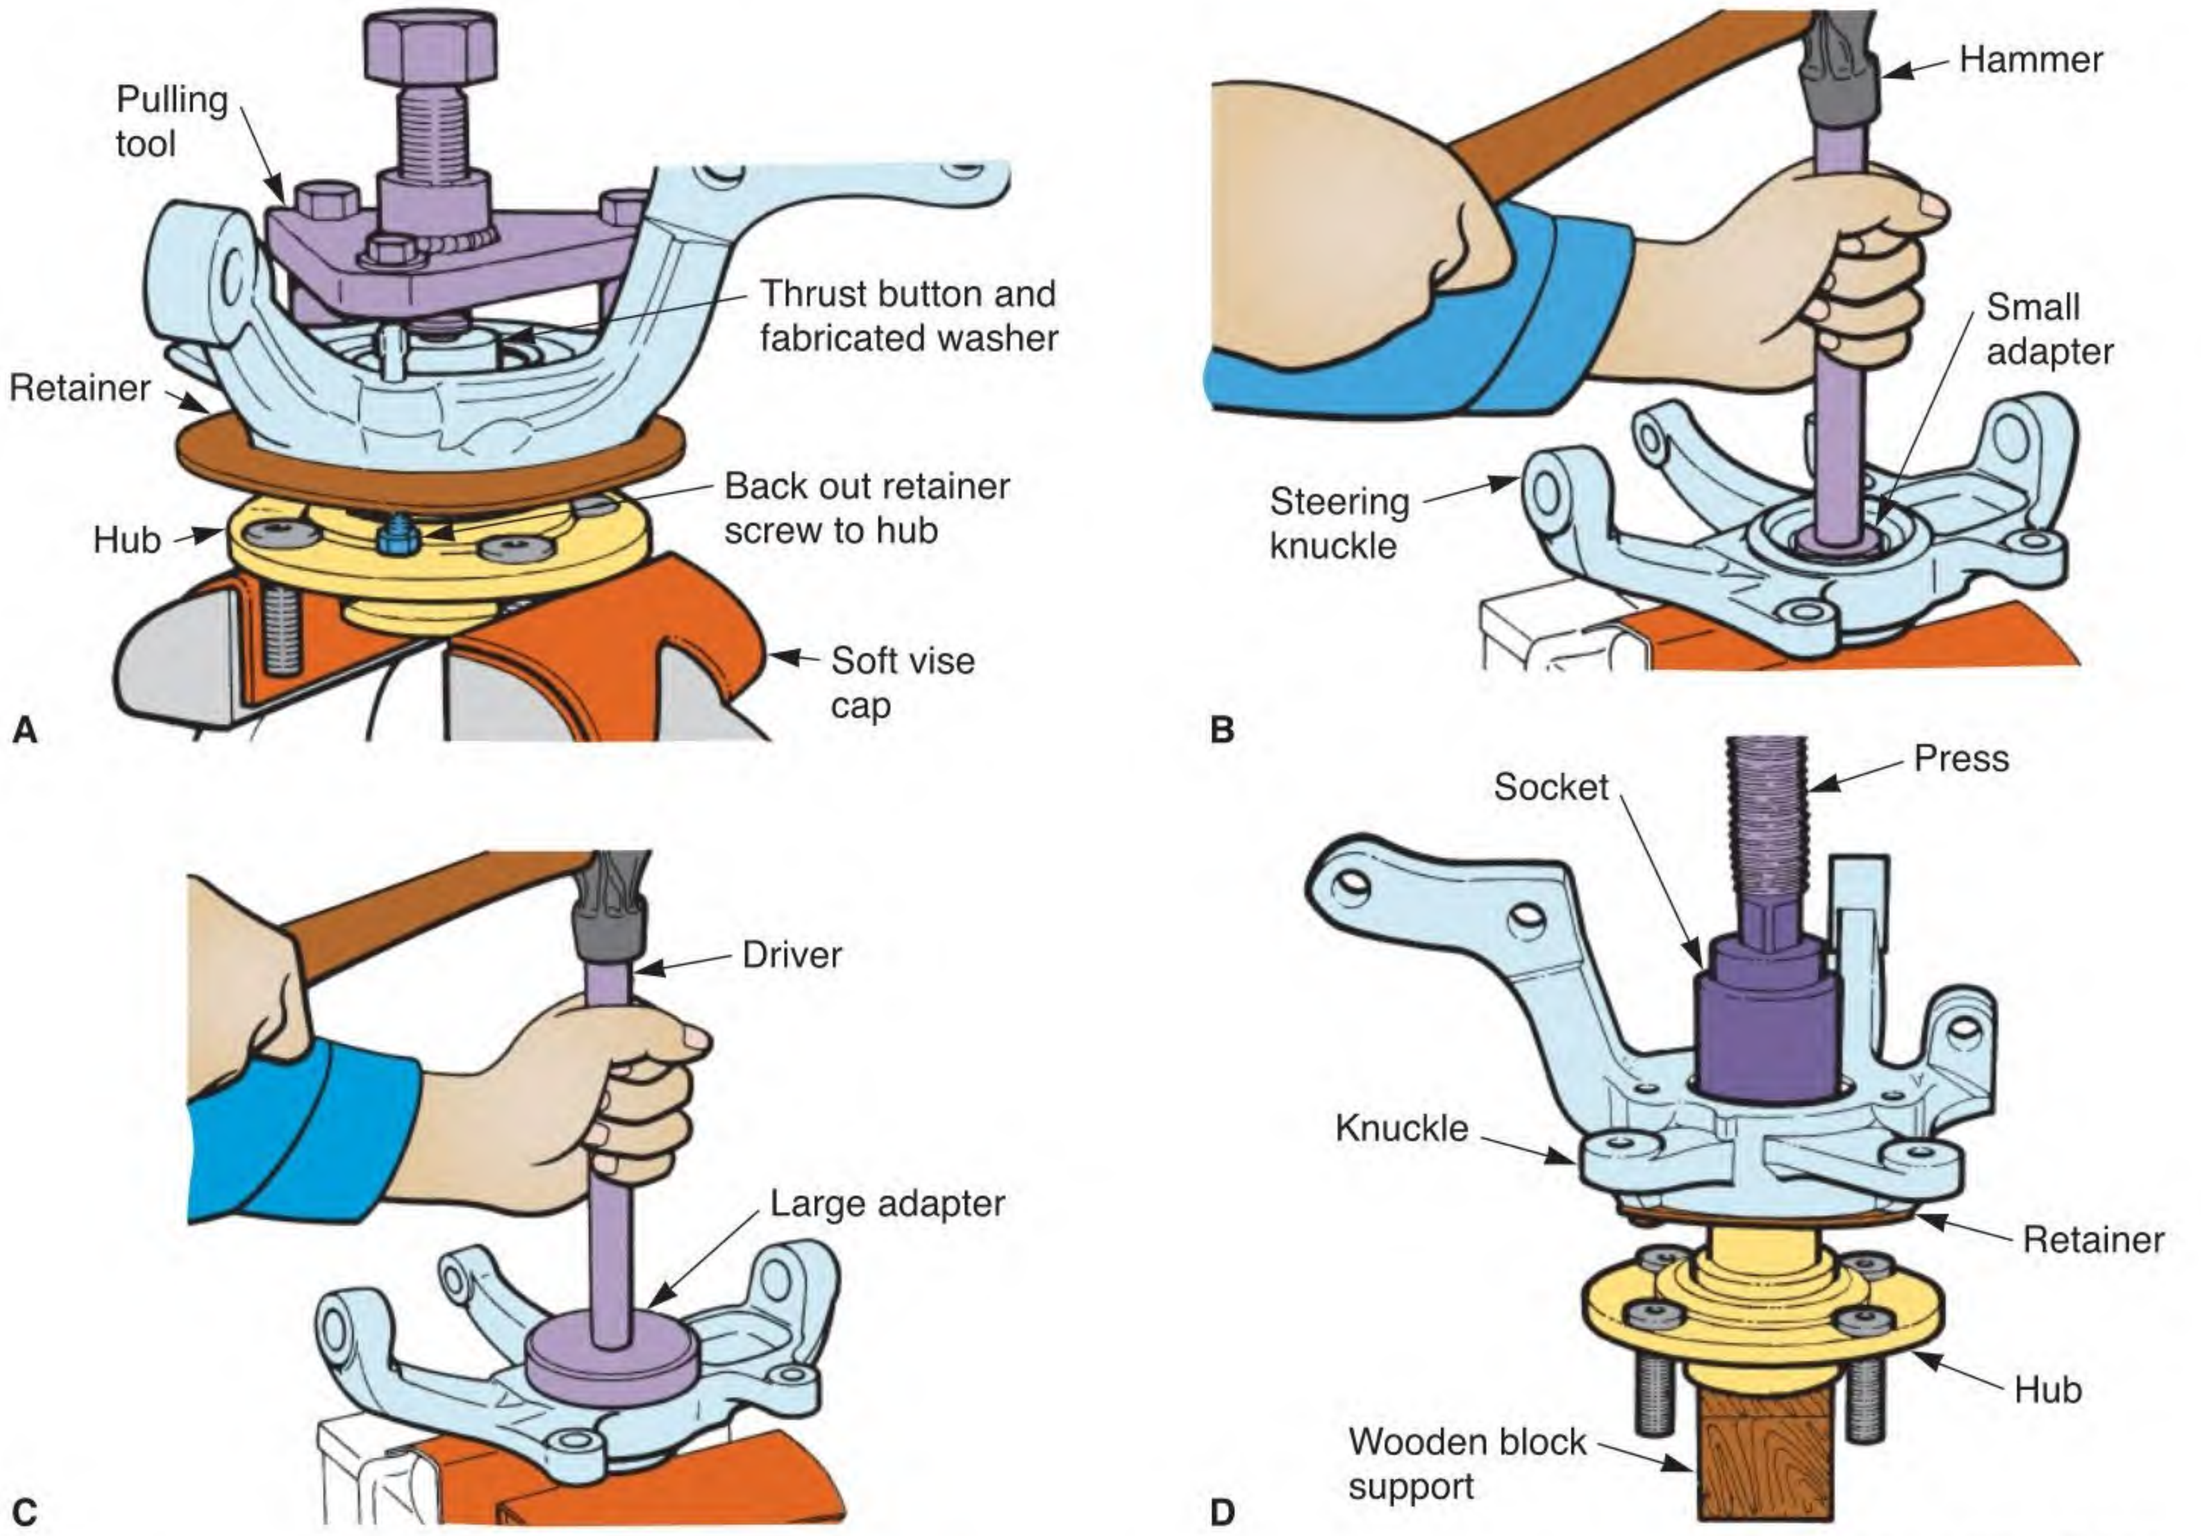
To service a front-drive ball-type wheel bearing:

1. Loosen the wheel lug nuts and spindle nut.
2. Raise the vehicle and secure it on jack stands.
3. Remove the lug nut or bolts, the wheel, and the axle nut.
4. Remove the caliper and hang it to one side.
5. Unbolt the brake disc from the hub, if needed.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 74-25. A driving hub assembly requires different service procedures than nondriving unit. The steering knuckle or bearing support must frequently be removed from car to service the bearings.



6. Remove the steering knuckle and hub assembly from the vehicle.
7. Depending on the design of the hub, you may need to remove the hub either before or after removing the steering knuckle. See **Figure 74-26A**.
8. After hub removal, remove the bearing using a hydraulic press or a driver.
9. Before installing new bearings, pack them with grease if they are not sealed units.
10. Using a press or driving tool, force the new bearings into place. Follow service manual procedures. See **Figure 74-26B**.

Warning

When pressing new front-wheel drive bearings into position, do *not* exceed manufacturer's press load limits. If excessive pressure is used, parts can shatter and throw metal shards into your work area. Wear eye protection and work gloves when using a hydraulic press on case hardened parts.

11. After pressing or driving the bearings into the steering knuckle or the bearing support, install a new grease seal.
12. Coat the inner lip of the grease seal with grease and the outer diameter with sealer.
13. Use a seal driving tool and light hammer taps to force the seal into the hub. Avoid excessive driving pressure that could bend or distort the seal body and cause leakage. Look at **Figure 74-26C**.
14. Press the hub into the steering knuckle and wheel bearing assembly, if needed. See **Figure 74-26D**.
15. When pressing the wheel bearing in or out, apply force to the correct bearing race (one press fit into part). Bearing damage will result if the incorrect race is pressed and jammed into the bearings. See **Figure 74-27**.
16. After assembling the wheel bearings, install the steering knuckle assembly on the vehicle.
17. Install the brake disc, caliper, and other components.
18. Make sure the spindle nut is tightened to specifications.
19. You may need to ***stake*** (dent or bend) the spindle nut or install a new lock nut and a new cotter pin, **Figure 74-28**.

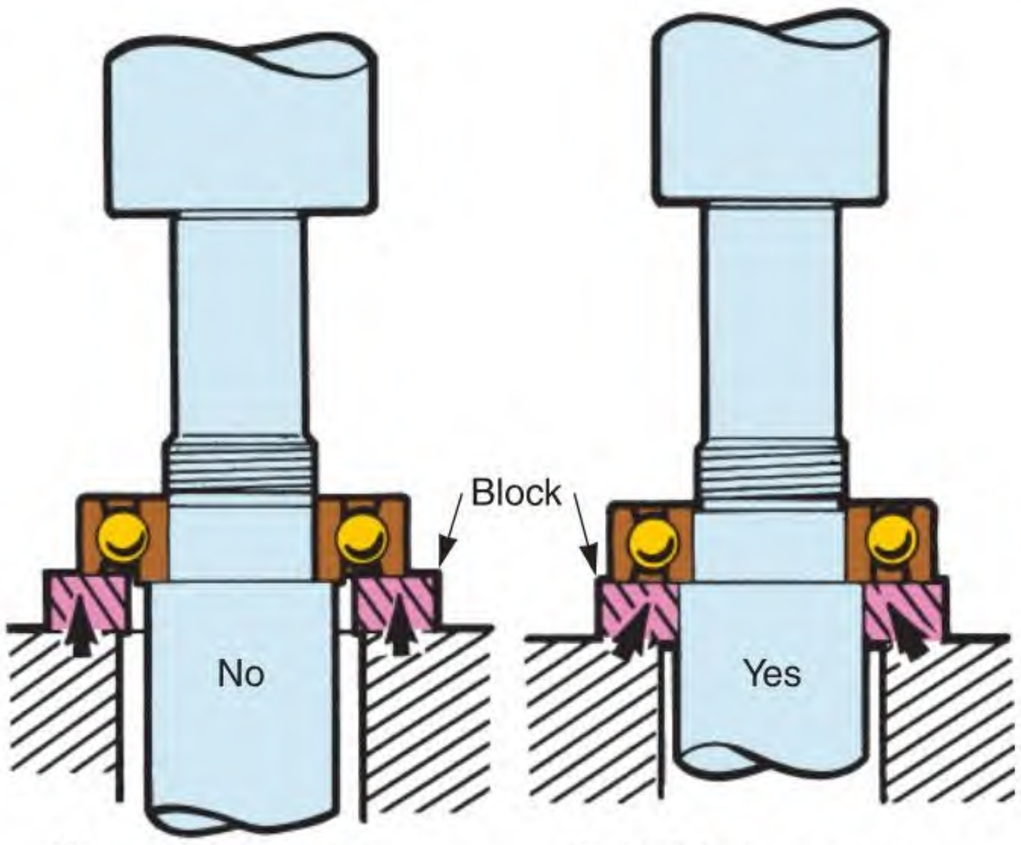
Goodheart-Willcox Publisher

Figure 74-26. Basic steps for replacing wheel bearings in driving hub assembly. A—After knuckle or support removal, use a special puller to remove the hub, if needed. B—Remove old bearings using a driver or hydraulic press. Wear safety glasses! C—Install the new bearings and grease seals. D—Use a press to reinstall the hub. Install new grease seals.



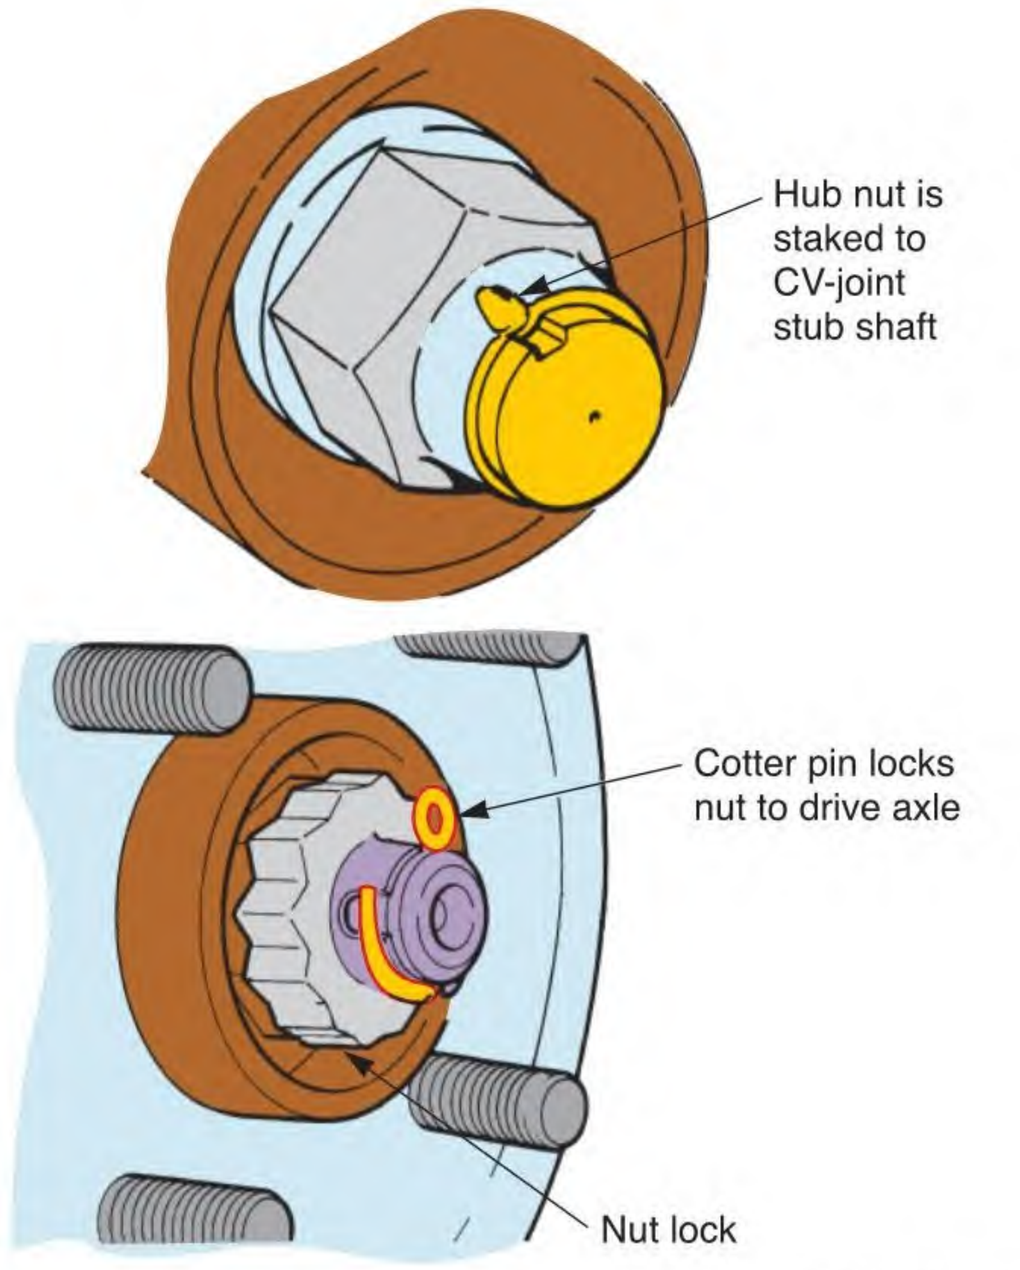
Replacing Nonserviceable Hub and Bearing Assembly

To replace a nonserviceable hub and bearing assembly, remove the bolts holding the bearing and hub assembly to the vehicle. When installing the new hub and bearing assembly, torque the bolts to specifications. Some manufacturers require new fasteners be used when bearings and hubs are replaced.

Tech Tip

A common and time-consuming mistake is to install a front-wheel drive wheel bearing backward. With some front-wheel drive bearings, only one edge has magnets for operating the wheel speed sensor and they are very difficult to see. Since both ends of the bearing have black plastic on them, you must look carefully to locate the tiny ribbing on the side that contains the magnets and trigger wheel. This side must face inward to be in close proximity to wheel speed sensor. If you install this type of front-wheel drive wheel bearing backward, it will trigger a bad wheel speed sensor code during the test-drive. You will have to do the whole repair over again for free to fix your mistake.

Copyright Goodheart-Willcox Co., Inc.



Wrong–Blocks contact bearing outer ring only, could ruin balls.

Right–Blocks contact inner ring–or both rings if bearing is flush faced.

Federal Mogul

Figure 74-27. When pressing bearings in or out, apply driving force so that pressure is not applied to the balls or rollers. This will prevent bearing damage.

Ford; Chrysler

Figure 74-28. After reassembling the driving hub and bearings, make sure you torque the spindle nut to specifications. Stake the spindle nut or install a cotter pin as recommended. This keeps front wheel and hub from coming off, possibly causing a serious accident.

Diagnostic Case Study

Concern: Mr. Watson brings his 2001 Toyota to the shop. He complains of a slight vibration in the steering wheel when driving.

Cause: Duff drives the car to verify the complaint, then raises the car on a lift. He spins each tire and inspects it closely. The tires look good, but he notices a small amount of runout on the lip of one of the lightweight aluminum rims. He turns the repair over to one of the shop's technicians.

The technician uses a dial indicator to check the runout of the rims. The radial and axial runouts are measured for each of the wheels. The two front wheels are bent beyond specifications from impact damage. The runout on the rear wheels is within specifications, less than 0.035" (0.89 mm).

Correction: The technician removes the front wheel-and-tire assemblies from the vehicle. She then uses a tire changer to dismount the front tires and install them on two new rims. Next, she reinstalls the wheels on the vehicle and tightens the lug nuts to factory specifications with a torque wrench. Finally, she test-drives the car and releases it to the customer.

Summary

- Tires are a common source of trouble. Normal wear, damage from road debris, and improper inflation pressure commonly cause tire failures.
- Tire problems usually show up as vibration, abnormal tread wear patterns, steering wheel pull, abnormal noises, and other similar symptoms.
- A tire wear pattern (area of tread worn *off*) can usually be studied to determine the cause of abnormal wear.
- Tire underinflation (low air pressure) is a very common and destructive problem that wears the outer corners of the tread.
- Tire overinflation (too much air pressure) causes the center area of the tread to wear.
- Tire vibration is commonly caused by an out-of-balance condition, ply separation, excessive tire runout, a bent wheel, tire stiffness variation, or tire cupping.

Copyright Goodheart-Willcox Co., Inc.

- Tire noise usually shows up as a thumping sound caused by ply separation or as a whine caused by abnormal tread wear (cupping, for example).
- Wheel bearing noise is normally produced by a dry, worn wheel bearing.
- Tire rotation involves changing the location of the tires on the vehicle to ensure maximum tire life.
- Lug nut torque is very important, especially on vehicles using mag wheels and lightweight hubs.
- Lateral runout is side-to-side movement. It is measured by placing a dial indicator against the side of the rim or on the tire sidewall.
- Radial runout is caused by a difference in diameter from the center axis of rotation.
- Static imbalance causes the tire to vibrate up and down.
- Dynamic imbalance makes the tire vibrate up and down and from side to side.
- A wheel assembly is balanced by adding wheel weights to the side opposite the heavy area found on the wheel/tire assembly.
- When mounting or dismounting a tire, a tire changing machine is used to force the tire on and off the wheel.
- Wheel bearings are normally filled with grease. If the grease dries out, the bearing will fail.
- Never use all-purpose wheel-bearing grease in wheel bearings on cars with disc brakes. The heat generated by the brakes can liquefy the grease and cause leakage out of the grease seals.
- When pressing a wheel bearing in or out, apply force to the correct bearing race (one press fit into part).

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

bead breaker
bearing packer
bubble balancer
dynamic imbalance
improper wheel balance
indirect tire pressure monitoring
lateral runout
lug nut torque
lug studs
off-car balancer
overinflation
ply separation
radial runout
road damage
stake
static imbalance
steering wheel pull
tire changer
tire changing machine
tire impact damage
tire load index number
tire maintenance
tire pressure gauge
tire rotation
tire runout
tire vibration
tire wear pattern
underinflation
wheel balancing machine
wheel bearing noise
wheel cap
wheel cover
wheel hop
wheel runout
wheel shimmy
wheel weights

Activities

1. On a vehicle assigned by your instructor, test a wheel bearing complaint and diagnose the problem.
2. Perform a tire rotation on a vehicle assigned by your instructor.
3. Demonstrate the procedure for balancing a wheel and tire. Describe each step of the procedure and explain why it is done.
4. Use a dial indicator to measure the lateral and radial runout of each wheel on a vehicle of your choice. Record your readings and compare them to specifications.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What are four common symptoms of tire problems?
2. Why is a tire wear pattern useful?
3. A customer complains of excessive right-front tire wear. The tread is worn along the outer edges. The center of the tread shows little wear. Technician A says that incorrect alignment is causing the wear and that the car needs a wheel alignment. Technician B says that underinflation could be the problem and that tire pressure should be checked. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

4. What is ply separation?
5. A metal ball peen hammer should be used to install wheel covers. True or False?
6. Why is periodic tire rotation important?
7. Excessive lug nut _____ can cause wheel or hub distortion.
8. Explain the difference between lateral runout and radial runout.
9. Describe the major differences between static and dynamic tire imbalance.
10. Which of the following is *not* a type of wheel balancer?
    (A) Dynamic wheel balancer.
    (B) Bubble balancer.
    (C) Neutral balancer.
    (D) Off-car balancer.
11. Often, a hole in a tire can be repaired by inserting a plug from the outside of the tire. True or False?
12. Define the phrase "pack the bearings."
13. All-purpose grease can be used to pack wheel bearings on a car with disc brakes. True or False?
14. Why should a new cotter pin be used when assembling a wheel bearing?
15. When pressing a ball bearing assembly in or out of the hub, what part of the bearing should contact the driving tool?

ASE-Type Questions

1. A car's left-front tire has a puncture hole. Technician A tells the owner of the car that this problem is called "tire impact damage." Technician B tells the owner of the car that this problem is called "tire road damage." Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
2. A car's front tires are worn excessively. Technician A checks the car's front-wheel alignment. Technician B checks the tire's inflation pressure. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
3. Bulges are discovered on an automobile's front tires. Technician A immediately replaces the tires. Technician B is not going to replace the tires until after determining the cause of the tire damage. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
4. The outer corners of a tire's tread are worn. Technician A checks to see if the tire is underinflated. Technician B says an underinflated tire will not produce this type of wear problem. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
5. An automobile has a steering wheel pull problem. Technician A checks to see if the tires are inflated evenly. Technician B checks for loose shock absorbers. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
6. A car is brought into the shop with a tire vibration problem. Technician A looks for ply separation. Technician B checks to see if the wheel is damaged. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
7. Vibration is coming from a car's center and rear. Technician A checks the condition of the rear tires. Technician B checks the front ball joints. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
8. A car is brought in with a noise coming from the right front tire. Technician A checks the tire's tread. Technician B looks for a worn wheel bearing. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

9. Vibration is coming from an automobile's front end. Technician A checks the condition of the car's front tires. Technician B says automotive tire problems will not produce front-end vibration. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. A customer wants her car's tires checked. Technician A checks for cracks. Technician B inspects the inner sidewall condition. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
11. An automobile is brought into the shop with damaged lug studs on the left wheel hub assembly. Technician A removes the damaged studs with a hammer and punch. Technician B uses a hydraulic press to remove the damaged studs. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
12. A customer wants his car's front wheel bearings greased. Technician A tells the customer that some automotive wheel bearings can be cleaned, packed with grease, and reinstalled. Technician B tells the customer that certain types of wheel bearings are sealed and must simply be removed and replaced. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
13. A car equipped with disc brakes is brought into the shop with worn front wheel bearings. Technician A replaces the bearings and packs the new bearings with all-purpose bearing grease. Technician B replaces the bearings and packs the new bearings with high-temperature wheel-bearing grease. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
14. Technician A says front wheel bearings on a driving hub and ball-type wheel bearing assembly are serviced during a brake job. Technician B says this type of wheel bearing assembly is not normally serviced. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
15. Technician A says if rear wheel bearings are dry and noisy when turned by hand, they should be replaced. Technician B says the fasteners on the rear wheel bearing and assembly should exceed the vehicle's recommended torque to prevent bolts from coming loose. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Tire, Wheel, and Bearing Diagnosis

Condition	Possible Causes	Correction
Wheel tramp.	1. Brake drum, rotor, wheel, or tire out of static balance. 2. Wheel or tire out-of-round (excessive radial runout). 3. Bulge on tire. 4. Loose or worn wheel bearings.	1. Balance assembly statically and dynamically. 2. Change tire position on wheel or discard tire or wheel as needed. 3. Replace tire. 4. Adjust or replace bearings.
Wheel shimmy.	1. Wheel and tire assembly out of dynamic balance. 2. Uneven tire pressure. 3. Worn or loose front wheel bearings. 4. Excessive tire or wheel runout. 5. Worn tires. 6. Low tire pressure. 7. Loose wheel lugs. 8. Bent wheel. 9. Incorrect wheel alignment.	1. Balance assembly statically and dynamically. 2. Inflate both front tires to same pressure. 3. Adjust or replace bearings. 4. Correct by moving tire on rim or replace defective parts. 5. Move to rear if still serviceable. 6. Inflate tires to correct pressure. 7. Tighten lugs. 8. Replace wheel. 9. Correct alignment. See Chapter 79.
Poor recovery following turns and/or hard steering.	1. Low tire pressure. 2. Lack of lubrication. 3. Incorrect wheel alignment.	1. Inflate to proper pressure. 2. Lubricate steering system. 3. Correct alignment. See Chapter 79.
Vehicle pulls to one side.	1. Uneven tire pressure. 2. Tires not same size. 3. Worn or improperly adjusted wheel bearings. 4. Dragging brakes. 5. Incorrect wheel alignment.	1. Inflate both front tires to same pressure. 2. Install same size tires on both sides. 3. Adjust or replace bearings. 4. Adjust brakes. 5. Correct alignment. See Chapter 79.
Vehicle wanders from side to side.	1. Low or uneven tire pressure. 2. Worn or improperly adjusted front wheel bearings. 3. Vehicle overloaded or loaded too much on one side. 4. Incorrect wheel alignment.	1. Inflate tires to recommended pressure. 2. Replace or adjust wheel bearings. 3. Advise owner regarding vehicle load limits. 4. Correct alignment. See Chapter 79.
Tire squeal on corners.	1. Low tire pressure. 2. Excessive cornering speed. 3. Incorrect wheel alignment.	1. Inflate to recommended pressure. 2. Advise driver. 3. Correct alignment. See Chapter 79.
Loose, erratic steering.	1. Loose front wheel bearings. 2. Loose wheel lugs. 3. Wheel out of balance.	1. Replace or adjust. 2. Tighten lugs. 3. Balance wheel assembly.
Hard riding.	1. Excessive tire pressure. 2. Improper tire size. 3. Heavy-duty shock absorbers installed.	1. Reduce pressure to specifications. 2. Install correct size. 3. Advise driver and/or change shocks.

Tire, Wheel, and Bearing Diagnosis

Condition	Possible Causes	Correction
Noise from front or rear wheels.	1. Loose wheel lugs. 2. Defective wheel bearings. 3. Loose wheel bearings. 4. Lack of lubrication. 5. Lump or bulge on tire tread. 6. Rock or debris stuck in tire tread. 7. Damaged wheel. 8. Wheel hub loose on axle taper (where used). 9. Worn or defective wheel bearing.	1. Tighten lugs. 2. Replace wheel bearings. 3. Adjust wheel bearings. 4. Lubricate bearings. 5. Replace tire. 6. Remove rock or debris. 7. Replace wheel. 8. Inspect and tighten. 9. Replace wheel bearing.
Tires lose air.	1. Puncture. 2. Bent, dirty, or rusty rim flanges. 3. Leaking valve core or stem. 4. Striking curbs with excessive force. 5. Flaw in tire casing. 6. Excessive cornering speed, especially with low tire pressure. 7. Porous wheel rim.	1. Repair puncture. 2. Clean or replace wheel. 3. Replace as needed. 4. Advise driver. 5. Repair or replace tire. 6. Advise driver. 7. Repair porous wheel rim.
Tire wears in center.	1. Excessive pressure.	1. Reduce tire pressure to specifications.
Tire wears on one edge.	1. Incorrect wheel alignment. 2. High speed cornering.	1. Correct alignment. See Chapter 79. 2. Advise driver.
Tire wears on both sides.	1. Low tire pressure. 2. Overloading vehicle.	1. Inflate tires to specifications. 2. Advise driver.
Tire scuffing or feather edging.	1. Excessive cornering speed. 2. Improper tire pressure. 3. Wheel shimmy. 4. Excessive runout. 5. Incorrect wheel alignment.	1. Advise driver. 2. Inflate tires to specifications. 3. Balance wheels statically and dynamically. 4. Correct or replace tire or wheel. 5. Correct alignment. See Chapter 79.
Tire cupping.	1. Incorrect wheel alignment. 2. Improper tire pressure. 3. Excessive runout. 4. Wheel and tire assembly out of balance. 5. Worn or improperly adjusted wheel bearings. 6. Grabby brakes.	1. Correct alignment. See Chapter 79. 2. Inflate tires to specifications. 3. Correct or replace wheel or tire. 4. Balance both statically and dynamically. 5. Replace or adjust wheel bearings. 6. Repair brakes.
Heel and toe wear.	1. Grabby brakes. 2. Heavy acceleration.	1. Repair brakes. 2. Advise driver.

Chapter 75
Suspension System Technology

After studying this chapter, you will be able to:

- Identify the major parts of a suspension system.
- Describe the basic function of each suspension system component.
- Compare the various types of suspension systems.
- Explain the operation of the four common types of springs.
- Explain automatic suspension leveling systems.
- Correctly answer ASE certification test questions requiring a knowledge of suspension system construction and design.

The ***suspension system*** allows a vehicle's tires and wheels to move up and down over bumps and holes in the road. It makes the vehicle ride more smoothly over rough roads. The suspension system consists of a series of arms, rods, ball joints (swivel joints), bushings, and other parts.

The suspension system works in unison with the tires, unibody or frame, wheels, wheel bearings, brake system, and steering system to provide a safe and comfortable means of transportation.

This chapter will summarize the most important parts of a basic suspension system and introduce the most common suspension system designs. It will also prepare you to better understand information on the diagnosis and repair of suspension systems.

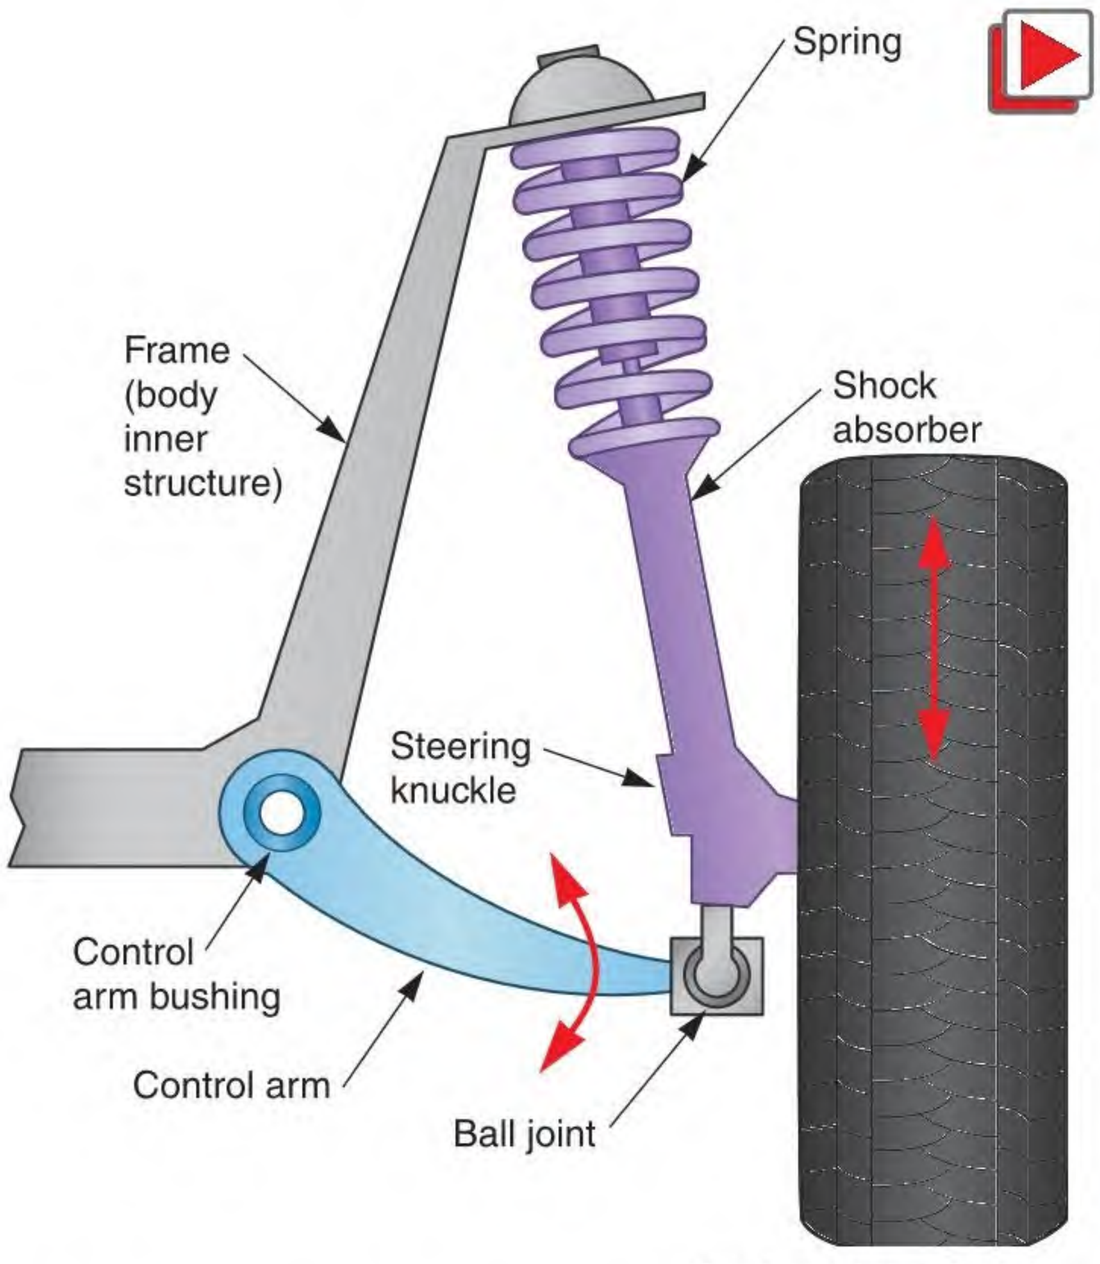
Functions of a Suspension System

A suspension system has several important functions:

- Supports the weight of the frame, body, engine, transmission, drive train, and passengers.
- Provides a smooth, comfortable ride by allowing the wheels and tires to move up and down with minimum movement of the vehicle body.
- Allows rapid cornering without extreme ***body roll*** (vehicle leans to one side).
- Keeps the tires in firm contact with the road, even after striking bumps or holes in the road.
- Prevents excessive ***body squat*** (body tilts down in rear) when accelerating or heavily loaded.
- Prevents excessive ***body dive*** (body tilts down in front) when braking.
- Allows the front wheels to turn from side to side for steering.

Copyright Goodheart-Willcox Co., Inc.

- Works with the steering system to help keep the wheels in correct alignment.



As you will learn, a suspension system uses springs, swivel joints, dampening devices, movable arms, and other components to accomplish these functions.

Tech Tip

Chassis stiffness is a primary factor affecting the quietness and smoothness of a vehicle's ride—the stiffer the chassis, the better. ***Chassis hertz*** is a measurement of the stiffness of a vehicle's structure. A high-hertz chassis (25 hertz, for example) is stiffer and stronger than a low-hertz chassis.

Basic Suspension System

Before discussing suspension system components in detail, you should be able to visualize each major part and understand how it functions in relation to the other parts. See **Figure 75-1**.

Goodheart-Willcox Publisher

Figure 75-1. Review the elementary parts and motion of a simplified car suspension system.

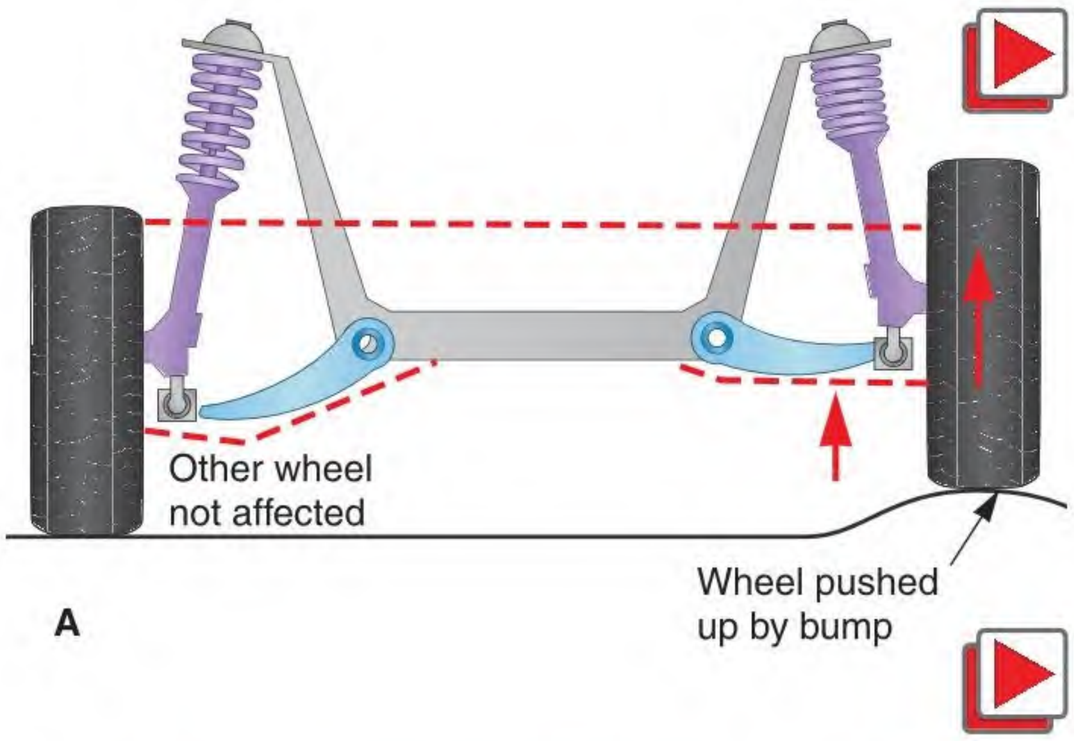
The following are basic parts of a suspension system:

- Control arm—The control arm is a movable lever that fastens the steering knuckle to the vehicle's body or frame.
- Steering knuckle—The steering knuckle provides a spindle or bearing support for the wheel hub, bearings, and wheel assembly.
- Ball joint—The ball joint is a movable connection that allows the control arm to move up and down while allowing the steering knuckle to swivel from side to side.
- Suspension spring—Suspension springs support the weight of the vehicle and permit the control arm and wheel to move up and down.
- Shock absorber or damper—A shock absorber or damper helps keep the suspension from continuing to bounce after spring compression and extension.
- Control arm bushing—The control arm bushing is a sleeve that allows the control arm to swing up and down on the frame.

Types of Suspension Systems

Suspension systems may be grouped into two broad categories: independent and nonindependent. See **Figure 75-2**. Both can be found on today's cars and trucks. Passenger cars normally use independent suspension at all four wheels. Pickup trucks often have a solid rear axle with a nonindependent suspension at the rear.

Independent Suspension



Independent suspension allows one wheel to move up and down with minimal effect on the other wheels. Look at **Figure 75-2A**. Since each wheel in an independent suspension system is attached to its own suspension unit, movement of one wheel does *not* cause direct movement of the wheel on the other side of the vehicle.

There are many types of independent suspension systems, many of which will be discussed later in this chapter. Independent suspension is widely used on modern vehicles, especially passenger cars.

Nonindependent Suspension

Nonindependent suspension has both the right and left wheels attached to the same solid axle. A truck's solid axle carries and pulls a heavier load than a lighter

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 75-2. Comparison of independent and nonindependent suspension systems. A—Independent suspension allows one wheel to roll over a bump with minimal effect on the other wheel. B—Nonindependent suspension causes the action of one wheel to tilt and affect the other wheel.

independent car suspension system. When one tire hits a bump in the road, its upward movement causes a slight upward *tilt* of the other wheel. Hence, neither wheel is independent of the other, **Figure 75-2B**.

Understeer and Oversteer

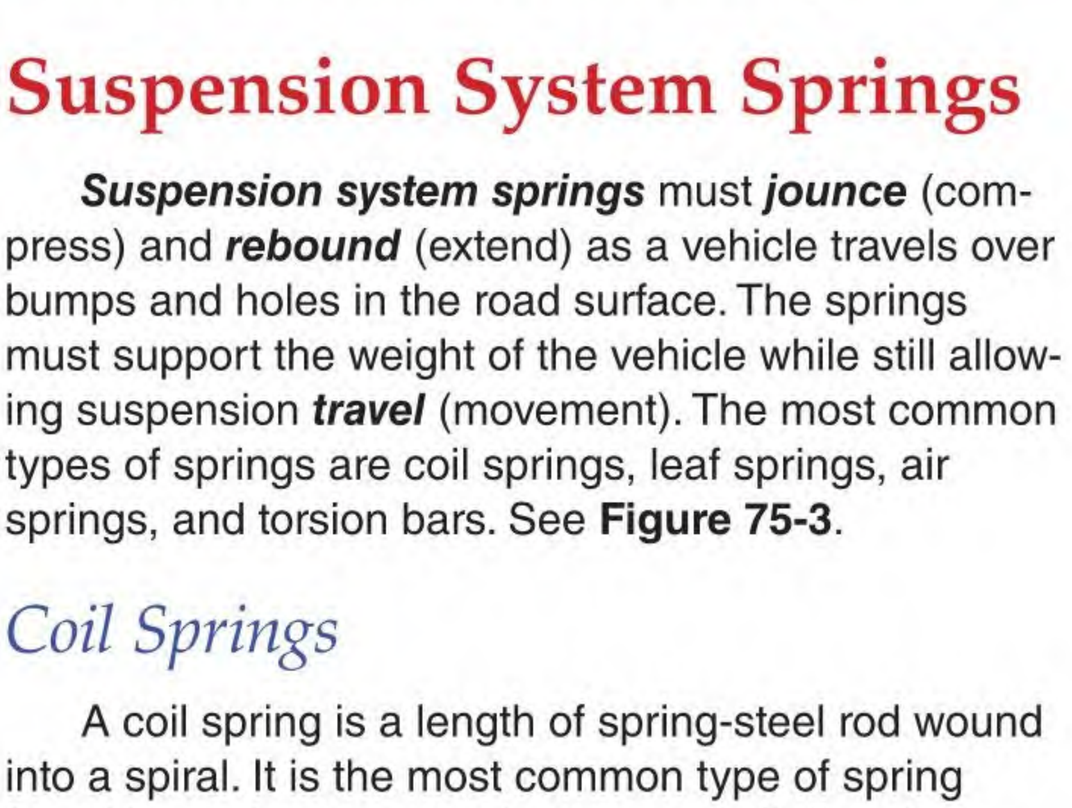
Understeer means that the vehicle is slow to respond to steering changes in a turn. The rear tires retain traction, but the front tires may slip on the road surface due to lack of downforce or other factors.

Oversteer basically means that the rear tires try to skid around sideways in a sharp or hard turn. The front tires retain traction, but the rear tires skid.

Suspension systems are designed to balance oversteer and understeer. The perfect suspension system provides ***neutral steering***—all four wheels have equal traction in turns.

Lateral Acceleration

Lateral acceleration is the amount of side force a vehicle can handle before its tires lose traction and skid in a sharp turn. It is measured in units of gravity, or "g-force," usually on a ***skidpad*** (round or circular driving course). The higher the "Gs," the better. Passenger cars can attain a lateral acceleration of about 1.0 G, while race cars can produce more than 3.0 Gs in turns.

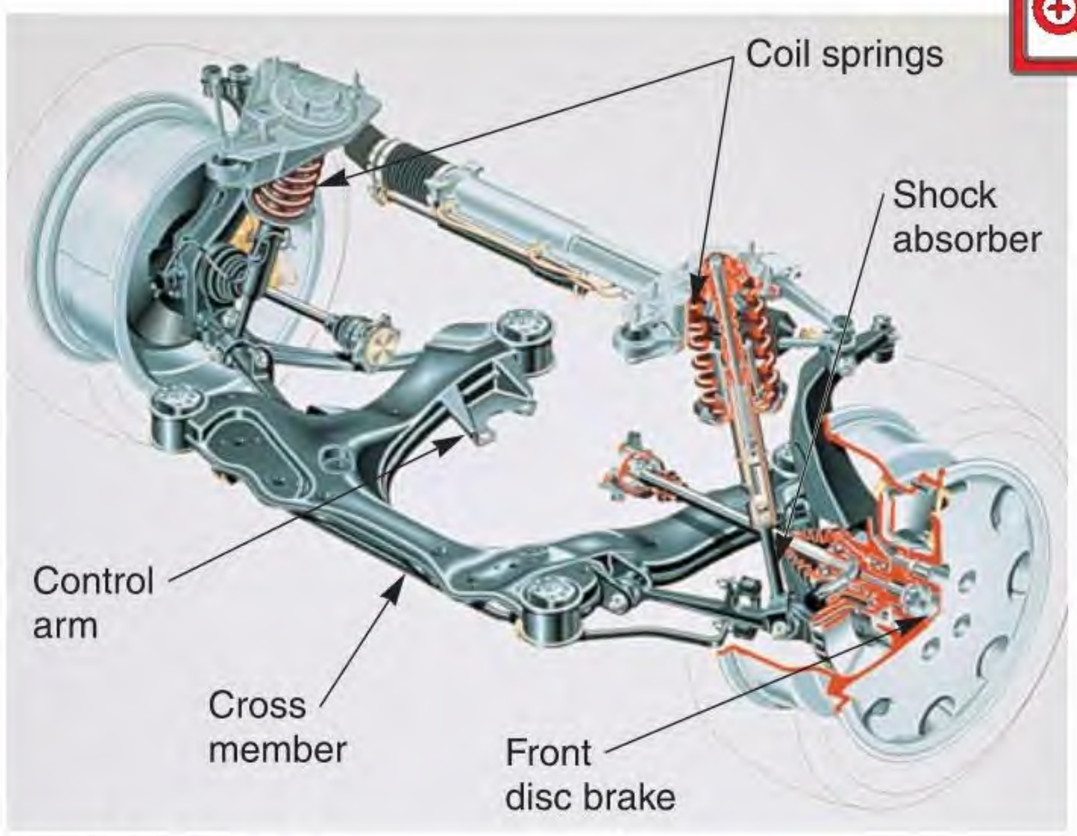


Independent suspension systems generally obtain higher lateral acceleration than nonindependent designs. Independent suspension systems are able to keep all four tires in full contact with the road surface better than older, heavier, solid-axle designs.

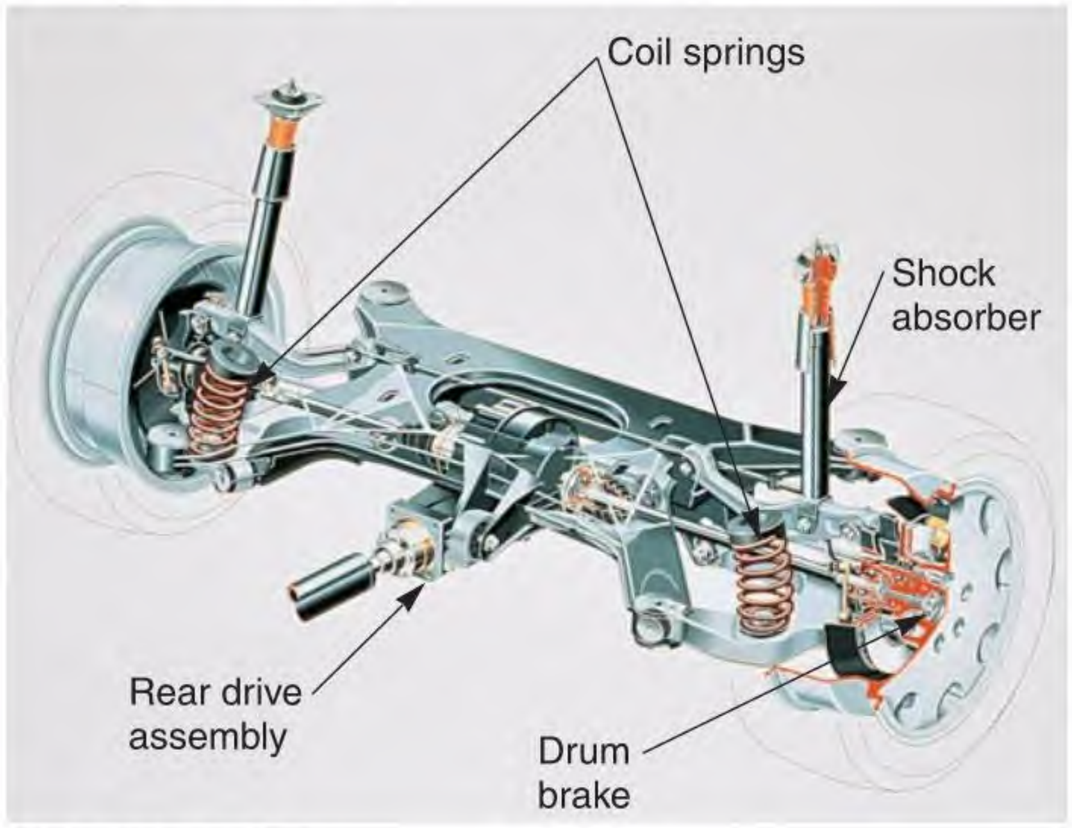
Suspension System Springs

Suspension system springs must ***jounce*** (compress) and ***rebound*** (extend) as a vehicle travels over bumps and holes in the road surface. The springs must support the weight of the vehicle while still allowing suspension ***travel*** (movement). The most common types of springs are coil springs, leaf springs, air springs, and torsion bars. See **Figure 75-3**.

Coil Springs



A coil spring is a length of spring-steel rod wound into a spiral. It is the most common type of spring found in modern suspension systems. Coil springs may be used on both the front and rear of a vehicle. See **Figure 75-4**.



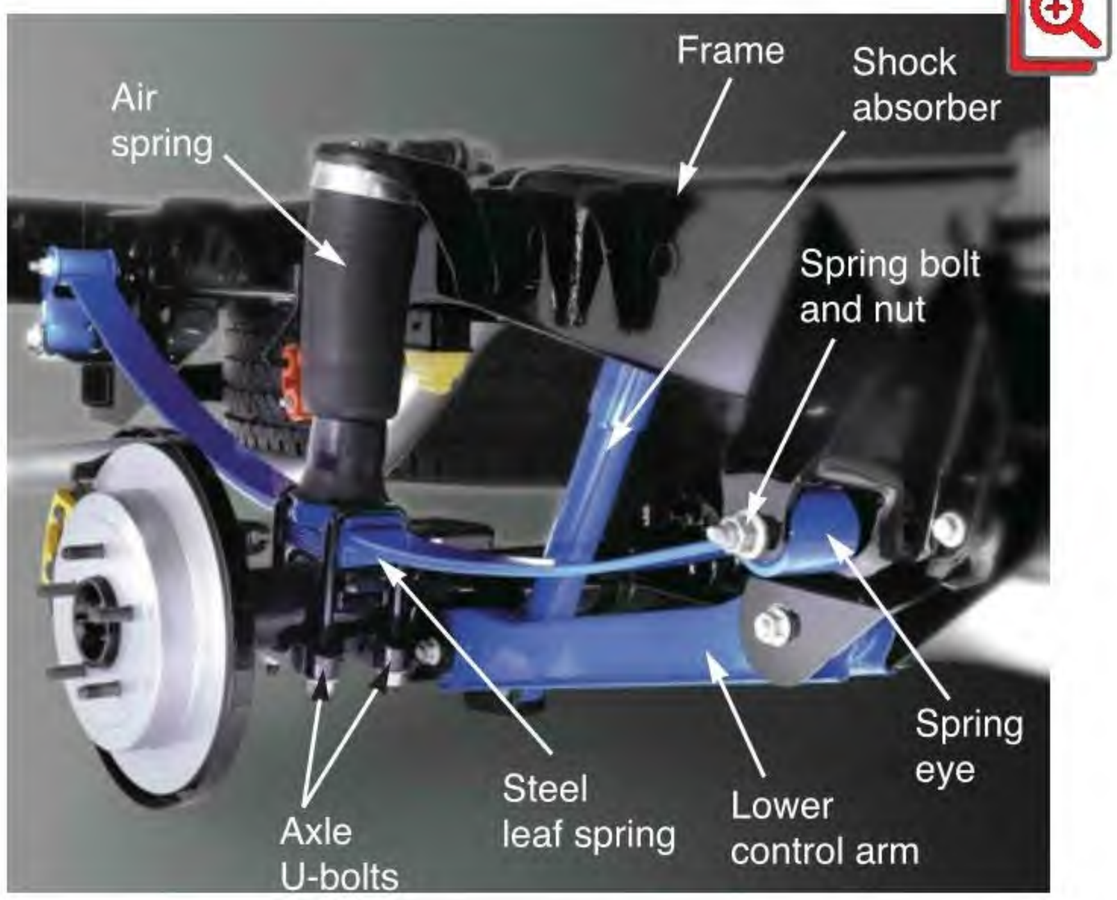
Goodheart-Willcox Publisher

Figure 75-3. Suspension system springs. A—Coil spring. B—Leaf spring. C—Air spring. D—Torsion bar.

Copyright Goodheart-Willcox Co., Inc.

Front suspension

Rear suspension



Audi

Figure 75-4. Both the front and rear of the vehicle may use coil springs. They are the most common springs used on passenger cars and light trucks.

Leaf Springs

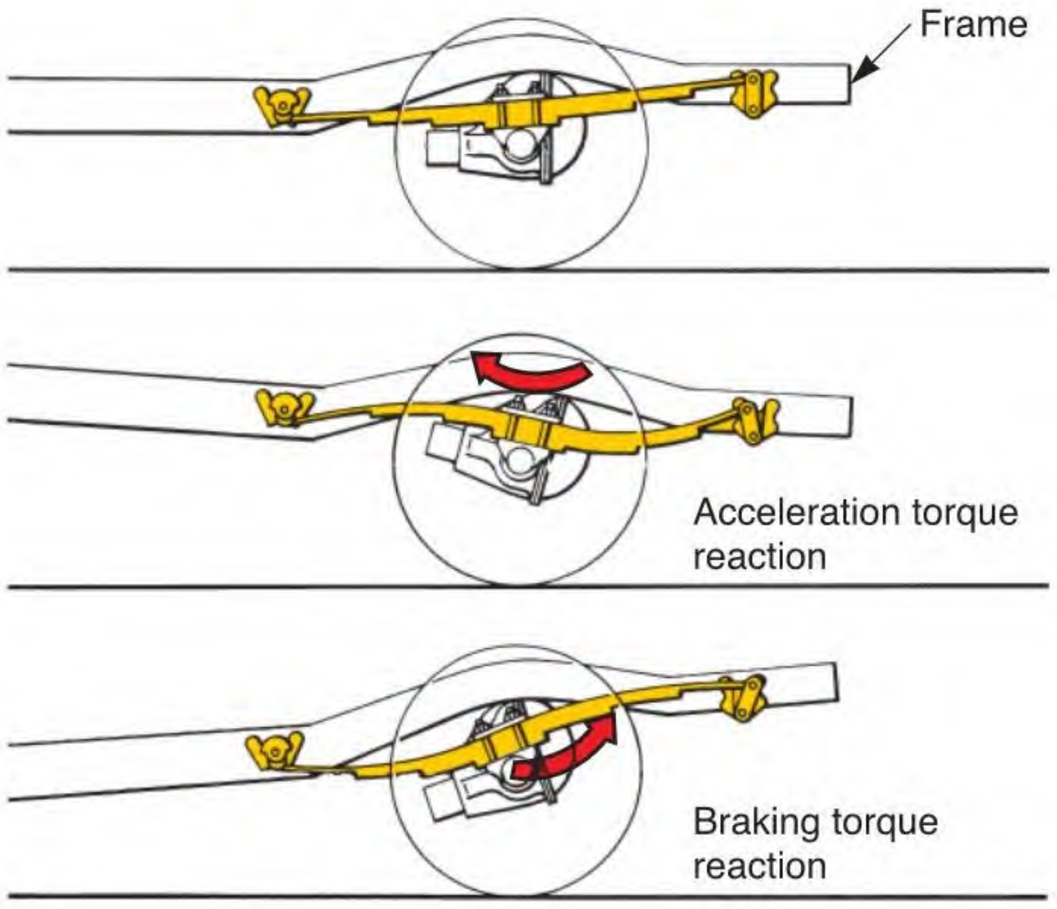
A ***leaf spring*** is commonly made of flat plates or strips of spring steel that are bolted together. A few are made of fiberglass. Although leaf springs were once used on front suspension systems, they are now limited to the rear of some cars. An exploded view of a leaf spring assembly is given in **Figure 75-5**.

A monoleaf spring is made of a single, thick leaf, which is usually made of reinforced fiberglass. Multiple-leaf springs have several thin steel leaves sandwiched together.

Ford

Figure 75-5. This single leaf spring is aided by an air spring that supports the weight of the truck and can adjust the ride height with different cargo loads.

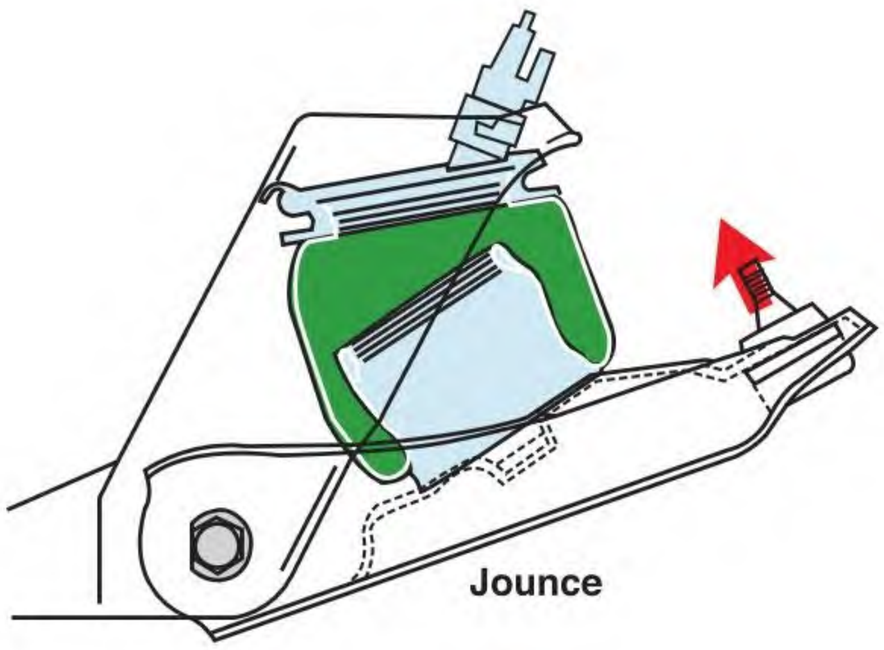
Each end of the leaf spring has an eye (cylinder shaped hole), which holds a bushing. The front spring eye normally bolts directly to the frame structure. Two large U-bolts secure the axle or axle housing to the leaf springs. A ***shackle*** fastens the rear leaf spring eye to the vehicle's frame and allows the spring to change length when bent. Shackles are short brackets that allow one end of the leaf spring to move from front to rear as its effect length changes with suspension movement. ***Insulators*** are synthetic rubber bushing and metal inserts that press-fit into the leaf spring eyes. They are placed between the springs to prevent squeaks and rattles.



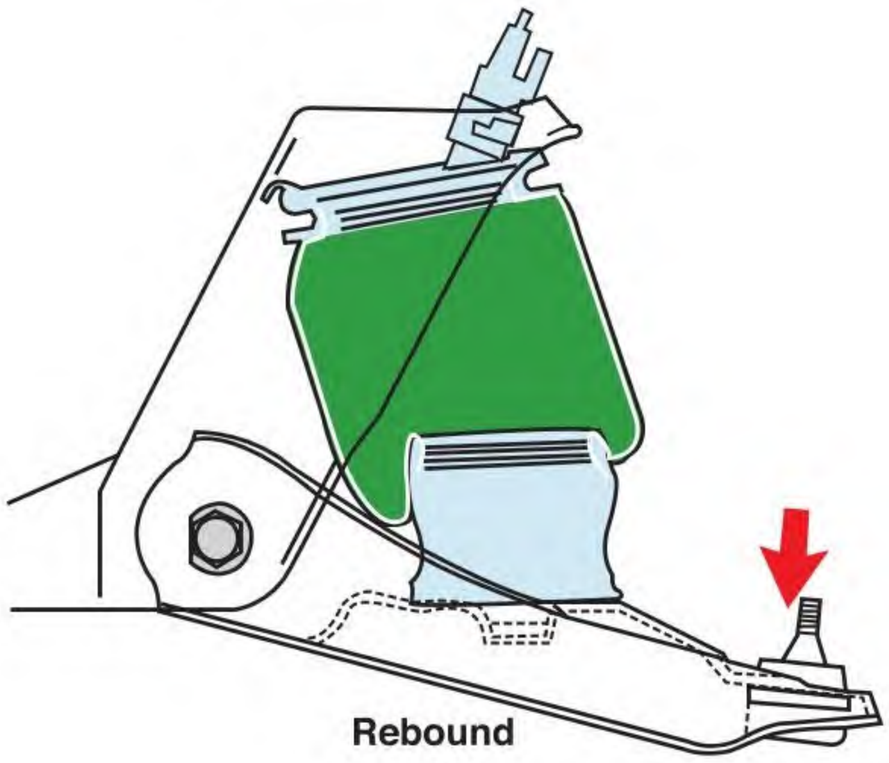
Leaf spring windup is a condition that causes the rear leaf springs to flex when driving or braking forces are applied to the suspension system. The twisting and distortion of the spring can cause body squat and dive, **Figure 75-6**.

Air Springs

An ***air spring*** is typically a two-ply rubber cylinder that is filled with air. End caps are formed on the air spring for mounting. Air pressure in the rubber cylinder gives the unit a spring action, similar to that of a coil spring. Refer to **Figure 75-7**.



An air spring is lighter than a coil spring. This gives an air spring the potential to produce a smoother ride than a coil spring. Special synthetic rubber compounds must be used so the air spring can



Copyright Goodheart-Willcox Co., Inc.

Ford

Figure 75-6. Leaf spring windup is a problem when leaves support driving axle. Torque tends to twist the springs.

Ford

Figure 75-7. Air springs are used on some late-model cars. They are especially adaptable to automatic leveling systems.

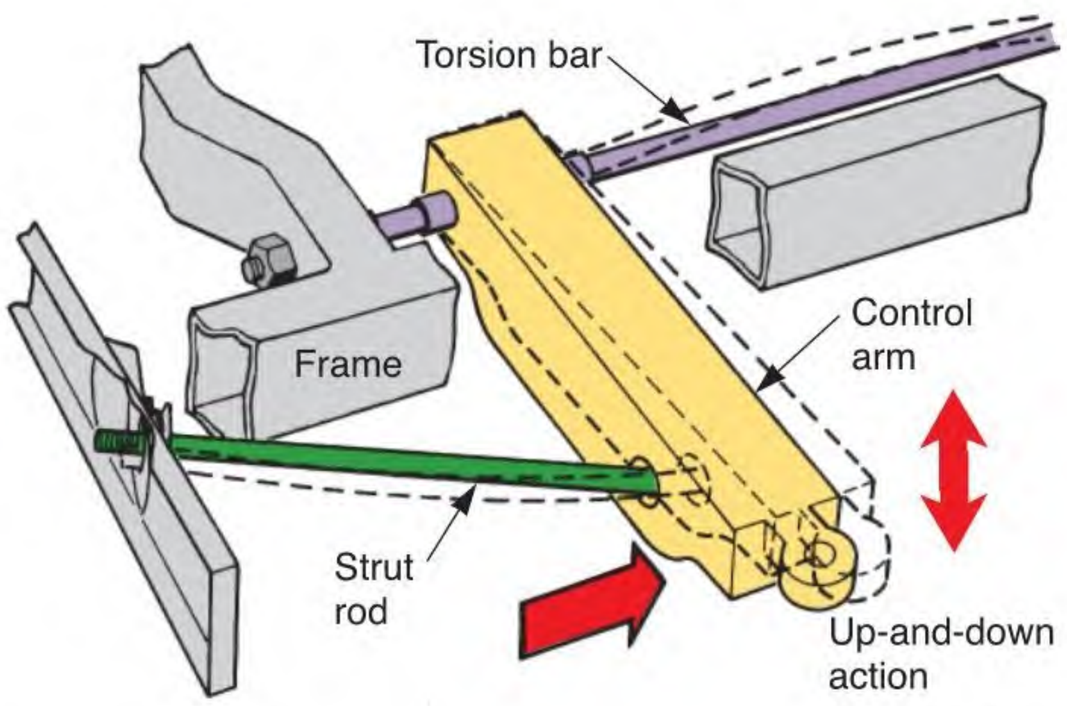
operate properly in cold weather—low temperatures tend to stiffen rubber.

Torsion Bars (Springs)

A ***torsion bar*** is made of a large spring-steel rod. One end of the torsion bar is attached to the frame. The other end is fastened to the suspension system control arm. See **Figure 75-8**.

Up-and-down movement of the suspension system twists the torsion bar. The bar then tries to return to its original shape, moving the control arm back into place.

Suspension Spring Specifications



There are several specifications relating to springs that you should understand. A few of the most important ones are discussed in the following section.

Spring rate refers to the stiffness, or tension, of a spring. The rate of a spring is determined by the weight needed to bend and compress it.

Sprung weight is the weight of the parts that are supported by the springs and suspension system. Sprung weight should be kept high in proportion to unsprung weight.

The ***unsprung weight*** is the weight of the parts that are *not* supported by the springs. The tires, wheels, wheel bearings, steering knuckles, and axle housing would be considered unsprung weight.

Unsprung weight should be kept *low* to improve ride smoothness. Movement of a high unsprung weight (heavy wheel and suspension components) would tend to transfer vibration to the passenger compartment.

Moog

Figure 75-8. The torsion bar is twisted with control arm movement. The bar resists twisting action and acts like a conventional spring.

Copyright Goodheart-Willcox Co., Inc.

Suspension System Construction

Now that you have been introduced to suspension system basics, we will cover the construction of each part in detail.

Control Arms

A ***control arm*** holds the steering knuckle, bearing support, or axle housing in position as the wheel moves up and down. Look at **Figure 75-9**.

The outer end of a control arm contains a ball joint; the inner end contains bushings. A rear suspension control arm may have bushings on both ends. Many modern suspension systems use four control arms: two on the top and two on the bottom. This helps reduce unsprung weight and adds more ball joints to carry the weight of the vehicle.

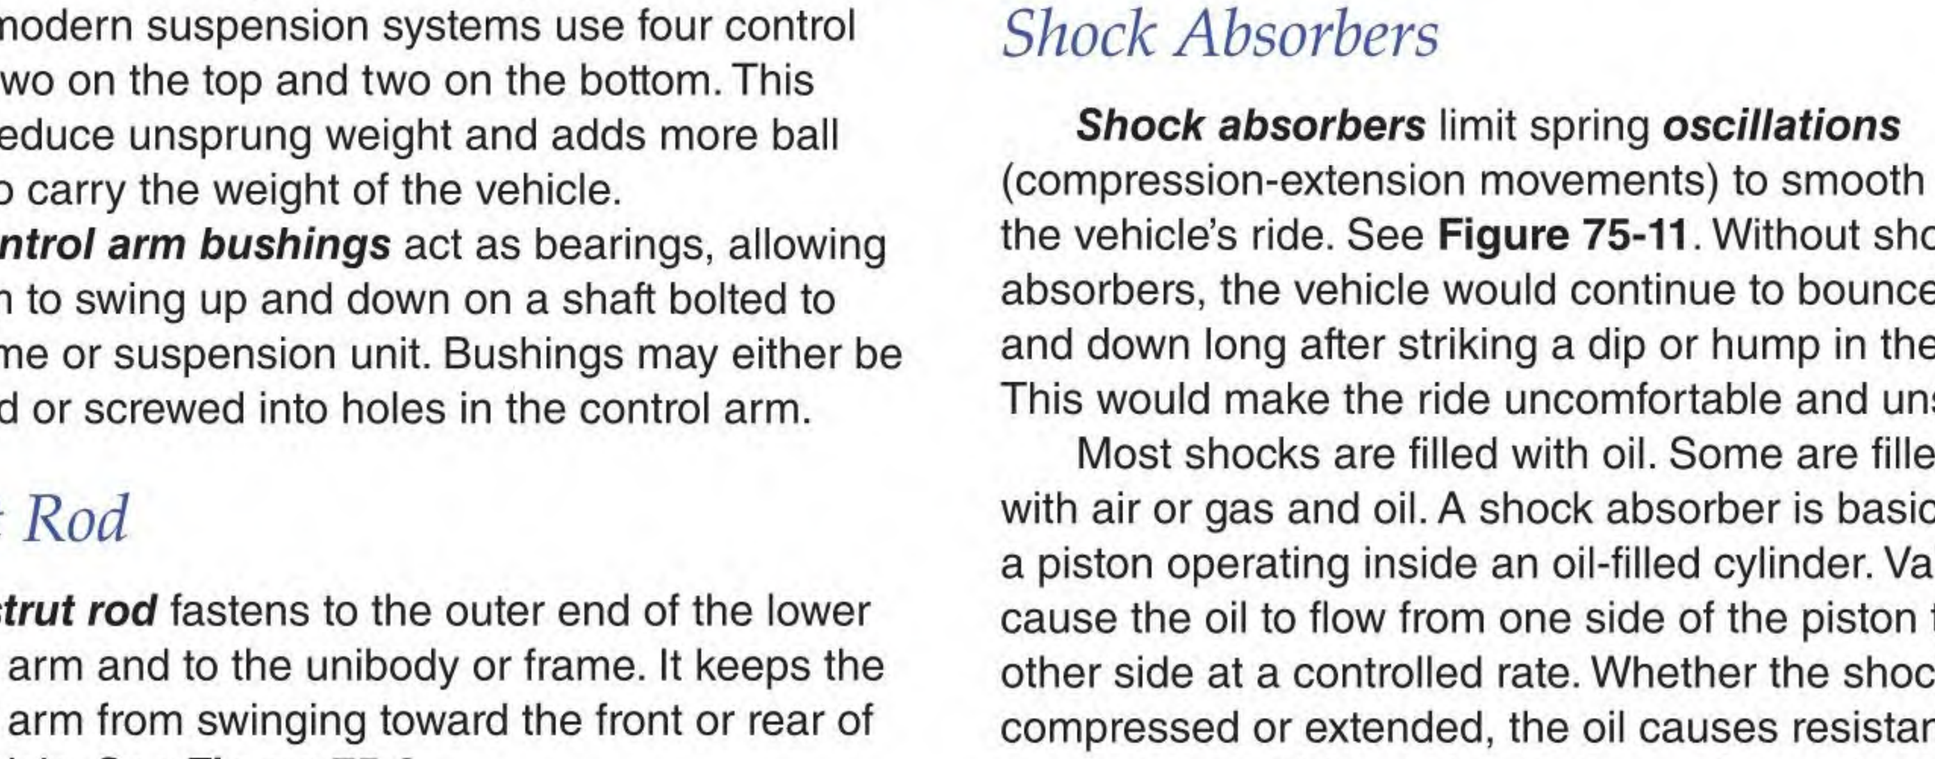
Control arm bushings act as bearings, allowing the arm to swing up and down on a shaft bolted to the frame or suspension unit. Bushings may either be pressed or screwed into holes in the control arm.

Strut Rod

A ***strut rod*** fastens to the outer end of the lower control arm and to the unibody or frame. It keeps the control arm from swinging toward the front or rear of the vehicle. See **Figure 75-8**.

The front of the strut rod contains rubber bushings that soften the action of the rod. They permit a controlled amount of lower control arm front-to-rear flex, while allowing full suspension travel.

Ball Joints

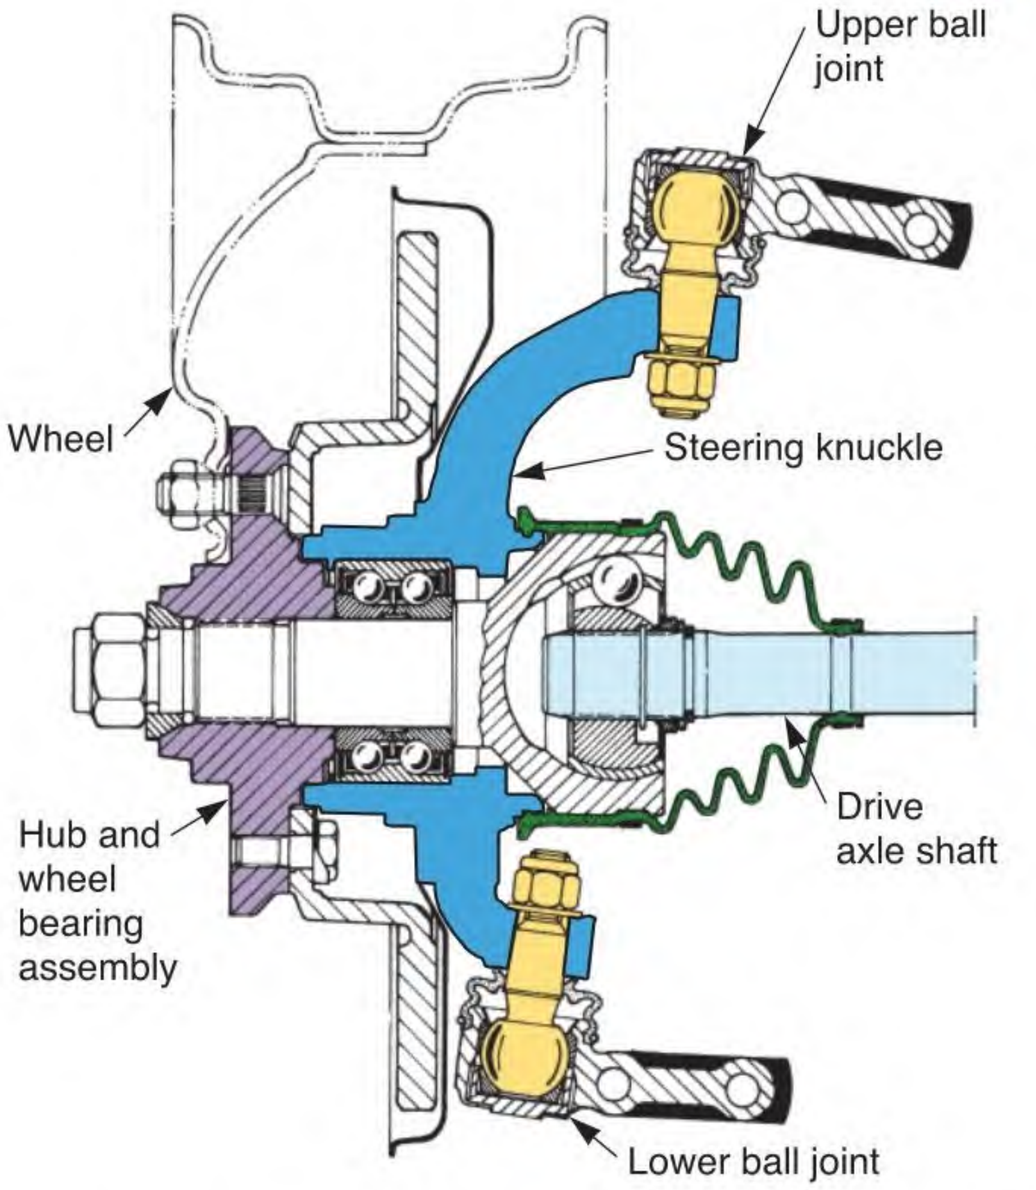


Ball joints (short for ball-and-socket joints) are connections that allow limited rotation in every direction. They connect the outer ends of control arms to the steering knuckle. See **Figure 75-10**.

Since the ball joint must be filled with grease, a grease fitting and a grease seal are normally placed on the joint. The end of the stud on the ball joint is threaded for a large nut. When the nut is tightened, it draws the tapered stud into the steering knuckle or bearing support, creating a force fit.

Shock Absorbers

Shock absorbers limit spring ***oscillations*** (compression-extension movements) to smooth the vehicle's ride. See **Figure 75-11**. Without shock absorbers, the vehicle would continue to bounce up and down long after striking a dip or hump in the road. This would make the ride uncomfortable and unsafe.



Most shocks are filled with oil. Some are filled with air or gas and oil. A shock absorber is basically a piston operating inside an oil-filled cylinder. Valves cause the oil to flow from one side of the piston to the other side at a controlled rate. Whether the shock is compressed or extended, the oil causes resistance to movement. This produces dampening action that restricts spring oscillations. Gas-pressure dampened shocks operate like conventional oil-filled shocks.

Fiat

Chrysler

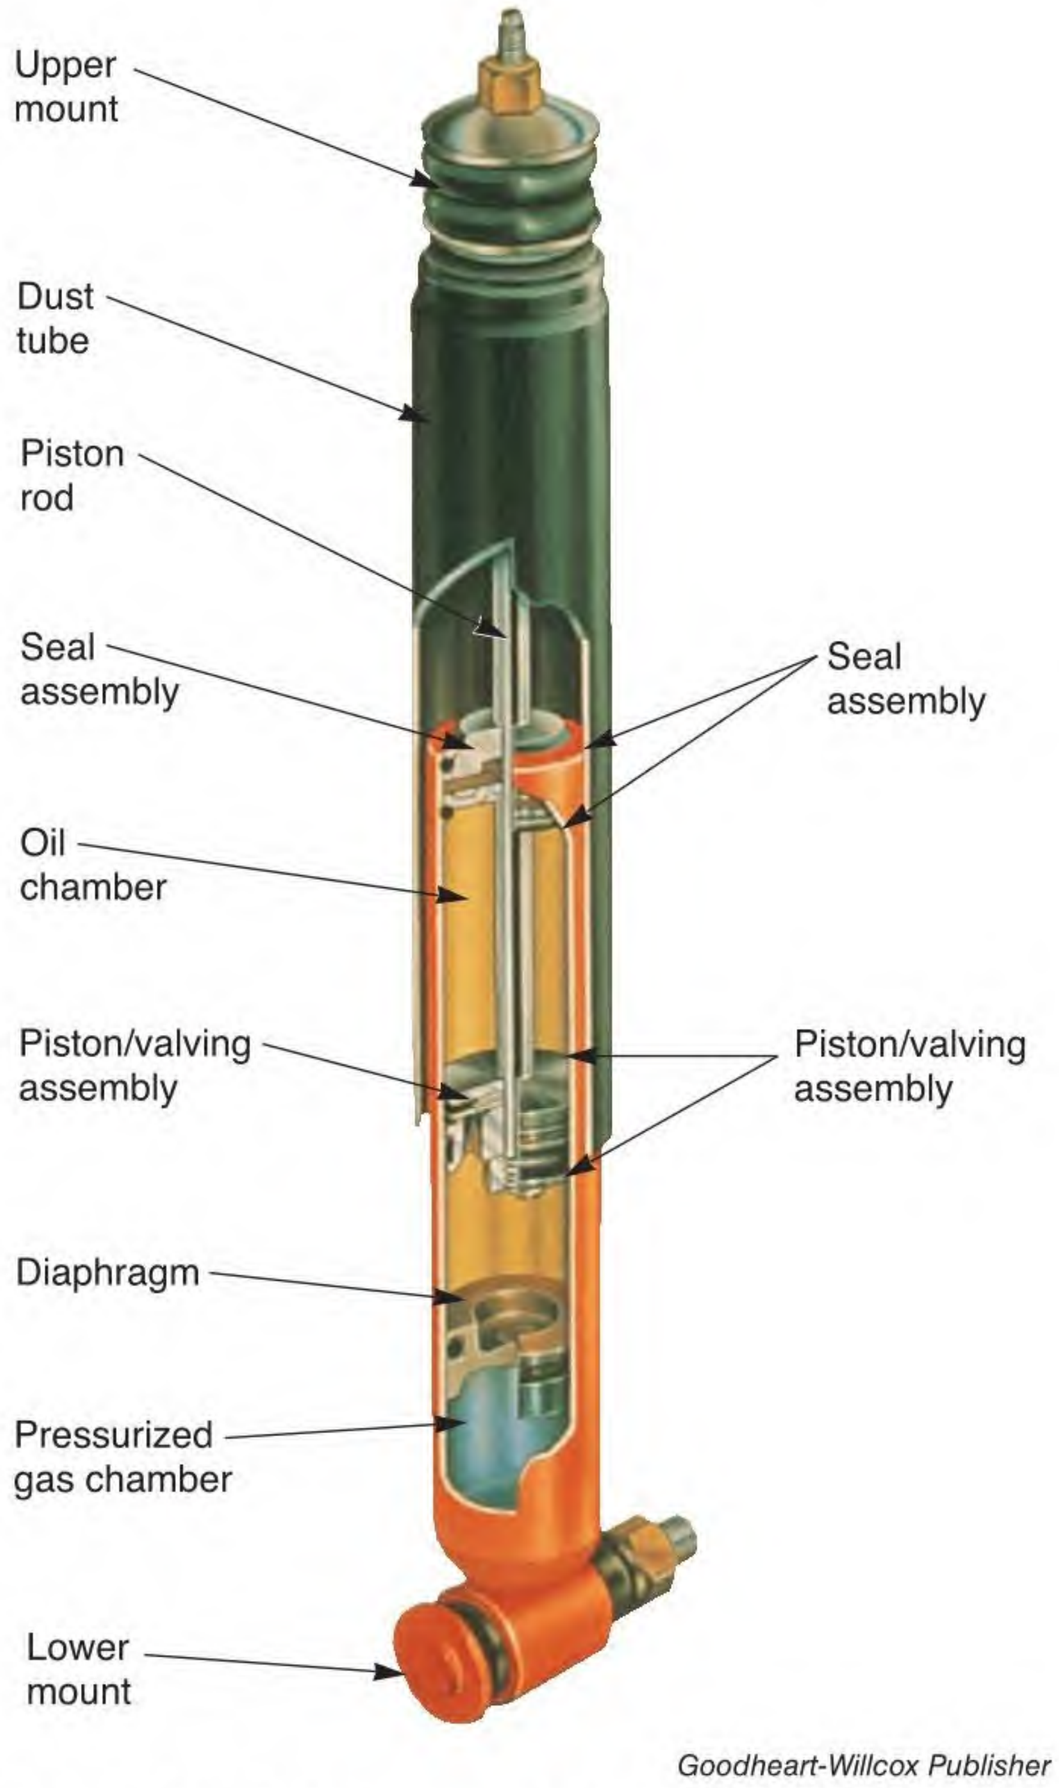

Figure 75-10. Cutaway view shows the ball joints, steering knuckle, and driving hub for a front-wheel-drive vehicle. Study the construction of the parts.

One end of the shock absorber connects to a suspension component, such as a control arm. The other end of the shock fastens to the vehicle's body or frame. In this way, the shock rod is pulled in and out and resists suspension system movements.

Shock absorber operation is illustrated in **Figure 75-12**. ***Shock absorber compression*** occurs when the vehicle's tire is forced upward upon hitting a bump. This compresses the coil spring and hydraulic shock absorber. ***Shock absorber extension*** is the outward movement of the piston and rod as the control arm moves down. This occurs right after a compression stroke or when the tire encounters a hole in the road.

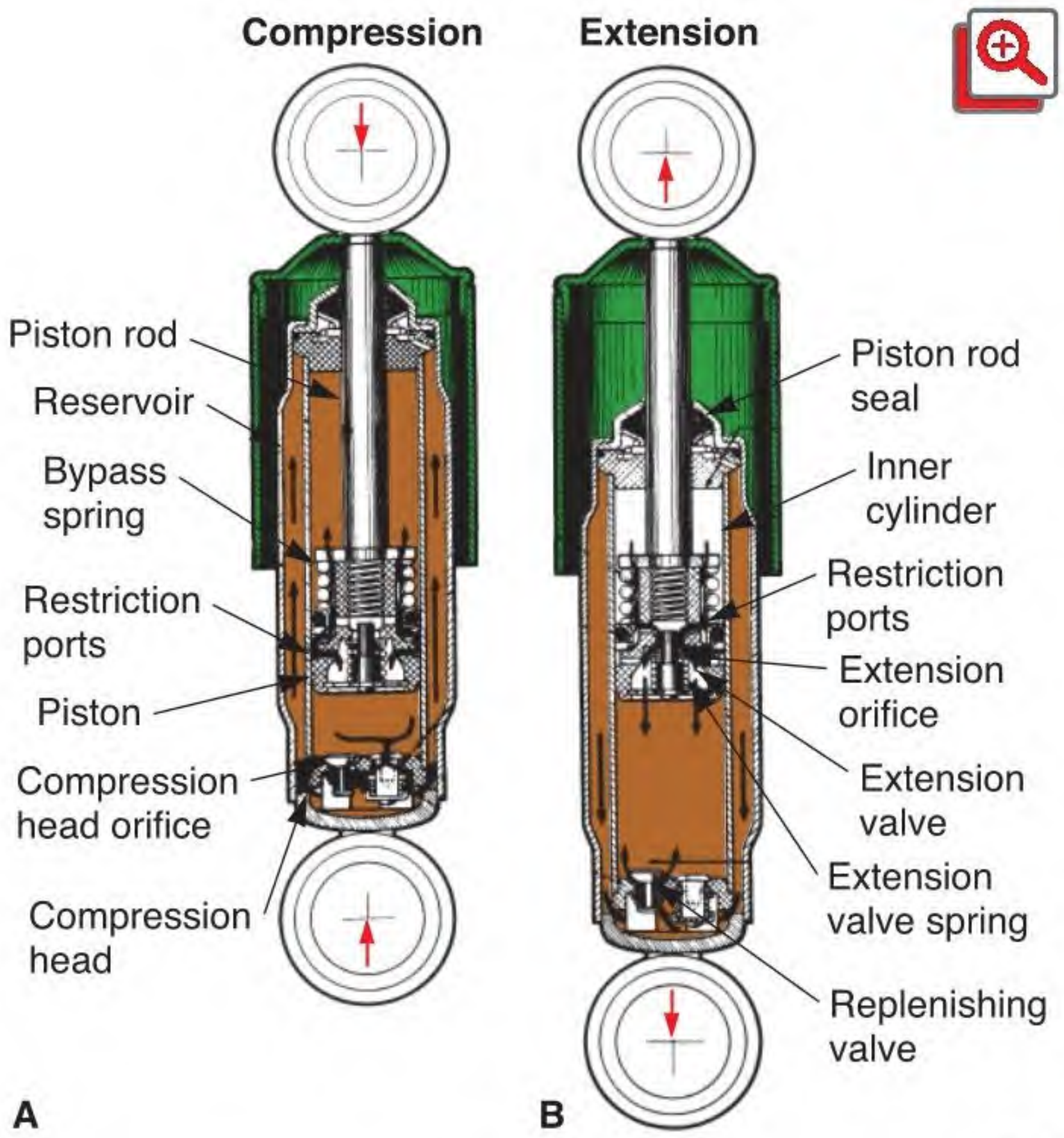
Gas-Charged Shock Absorbers

Gas-charged shock absorbers use a low-pressure gas to help keep the oil in the shock from foaming. Usually, nitrogen gas is enclosed in a chamber separate from the main oil cylinder. The shock piston operates in the oil. The gas maintains constant pressure on the oil to stop air bubbles from forming.

Goodheart-Willcox Publisher

Figure 75-11. Basic components of a shock absorber.

Self-Leveling Shock Absorbers



A ***self-leveling shock absorber*** uses a special design that causes a hydraulic lock action to help maintain normal vehicle curb height.

A valve system in each shock retains hydraulic pressure when the shock is compressed near its minimum length setting. This hydraulic lock action helps keep the shock rod at the same length with changes in force or curb weight. This tends to help keep the vehicle level under varying conditions.

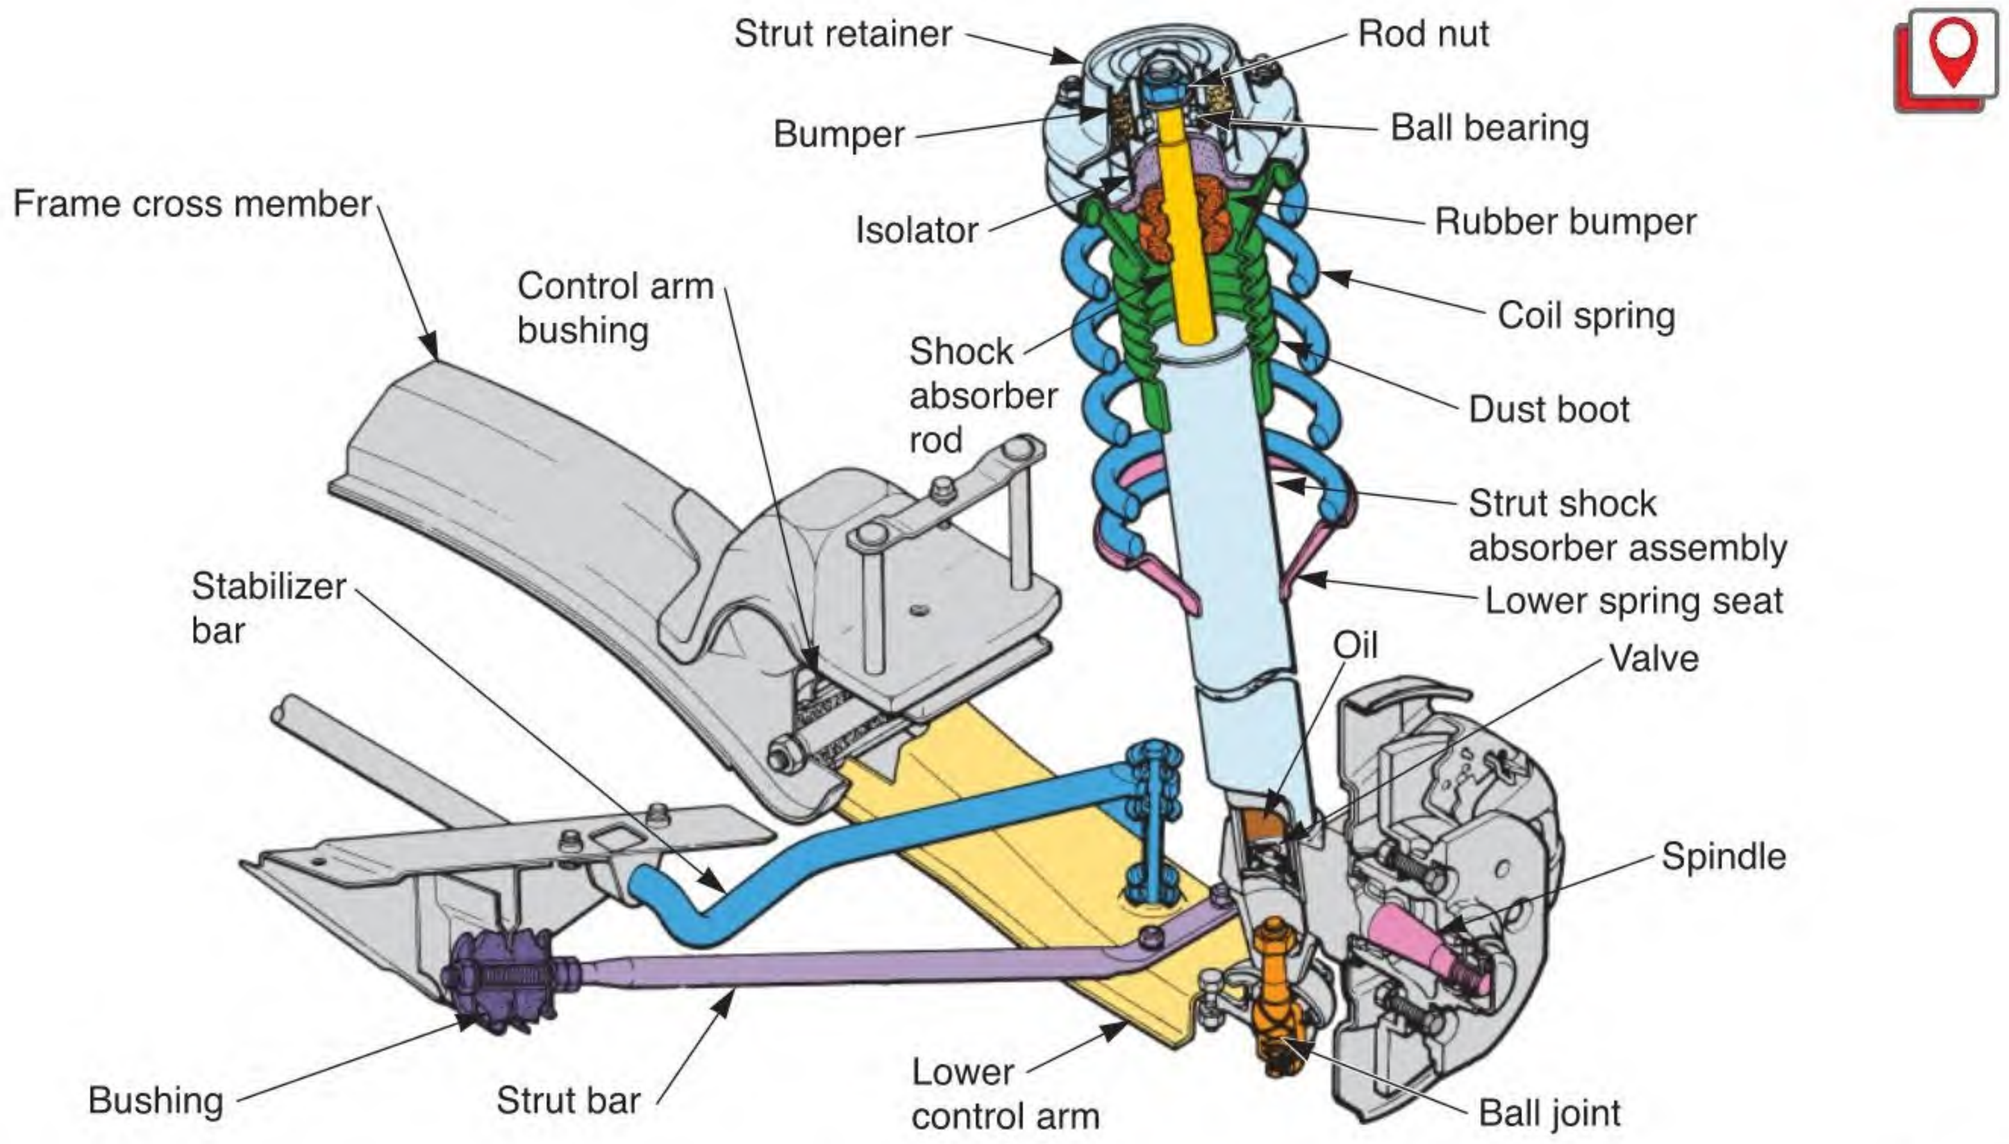
Adjustable Shocks

Adjustable shock absorbers provide a means of changing shock stiffness. Usually, by turning the shock outer body or an adjustment knob, you can set the shock soft for a smooth ride or stiff for better handling.

Copyright Goodheart-Willcox Co., Inc.

Gabriel

Figure 75-12. Cutaway view of a shock absorber in action. A—Compression stroke forces the piston down in the cylinder. Oil is forced into the upper area of the shock. B—Extension stroke causes oil to be pulled back into the lower area. Note the valve action.



Some electronic (computer-controlled) suspension systems automatically change shock dampening stiffness with road and driving conditions.

Strut Assembly

A ***strut assembly*** consists of a shock absorber, a coil spring (most types), and an upper damper unit. The strut often replaces the upper control arm. Only the lower control arm and the strut are needed to support the front wheel assembly.

The basic parts of a typical strut assembly are shown in **Figure 75-13**. They include:

- ***Strut shock absorber***—The strut shock absorber is a piston operating in an oil-filled (or oil and gas) cylinder to prevent coil spring oscillations.
- ***Dust shield***—A dust shield is a metal shroud or rubber boot that keeps road dirt off the shock absorber rod.
- ***Lower spring seat***—The lower spring seat is a lower mount formed around the shock body for the coil spring.
- ***Coil spring***—The coil spring supports the weight of the vehicle and allows suspension action.

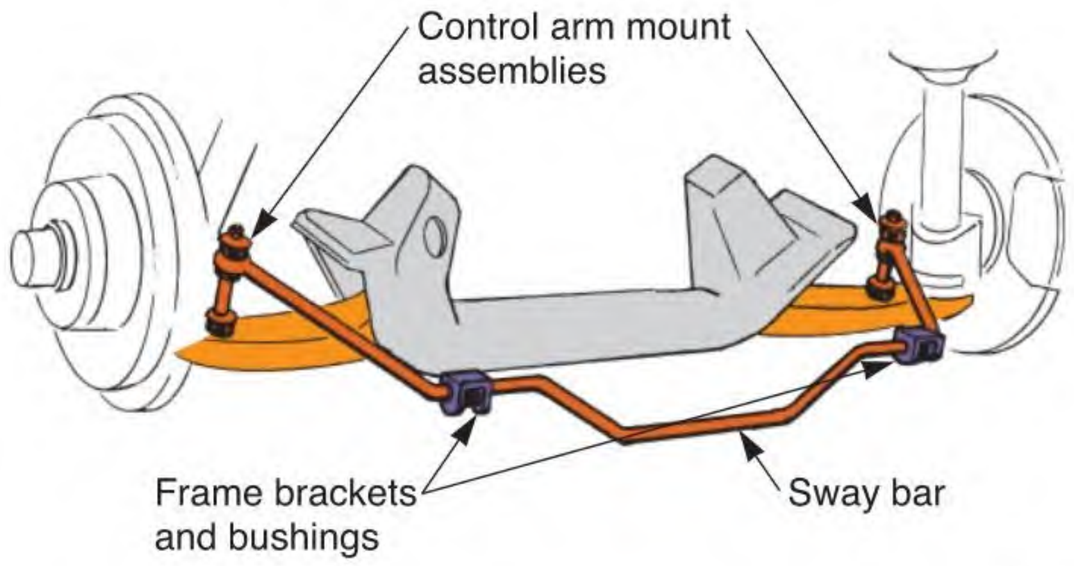
Chrysler

Figure 75-13. Study the parts of this strut assembly closely. This is one of the most modern suspension systems and is commonly used on today's vehicles.

Copyright Goodheart-Willcox Co., Inc.

- ***Upper spring seat***—The upper spring seat holds the upper end of the coil spring and contacts the strut bearing.
- ***Strut bearing***—The strut bearing is a ball bearing that allows the shock-and-spring assembly to rotate for steering action. It is only used on the front of the vehicle.
- ***Rubber bumpers***—Rubber bumpers are jounce and rebound bumpers that prevent metal-to-metal contact during extreme suspension compression and extension.
- ***Rubber isolators***—Rubber isolators prevent noise from transmitting into the body structure of the vehicle.
- ***Upper strut retainer***—The upper strut retainer secures the upper end of the strut assembly to the frame or unibody.
- ***Strut rod nut***—A strut rod nut is a hex nut that holds the shock absorber rod in the upper strut retainer.
- ***Damper unit***—The damper unit is a shock that fits inside a coil spring to prevent excessive jounce and rebound.

A strut shock absorber is similar to a conventional shock absorber. However, it is longer and has provisions (brackets or connections) for mounting and holding the steering knuckle (front of vehicle) or bearing support (rear of vehicle) and spring.



Sway Bar (Stabilizer Bar)

A ***sway bar***, or ***stabilizer bar***, is used to keep the body from leaning excessively in sharp turns. The sway bar is made of spring steel. It fastens to both lower control arms and to the frame. Rubber bushings fit between the bar and the control arms. Brackets and bushings are used to secure the bar to the frame. ***Sway bar links*** connect the sway bar to the control arms. See **Figure 75-14**.

When a vehicle rounds a corner, centrifugal force makes the outside of the body drop and the inside of the body rise. This twists the sway bar. The bar's resistance to this twisting motion limits body lean in corners.

Track Rod (Lateral Control Rod)

A ***track rod***, also known as a ***lateral control rod***, is sometimes used on rear suspension systems to prevent side-to-side axle movement during cornering. The track rod is almost parallel to the rear axle. One end of the rod is fastened to the axle, and the other end of the rod is fastened to the frame or body structure on the opposite side of the vehicle, **Figure 75-15**.

Moog

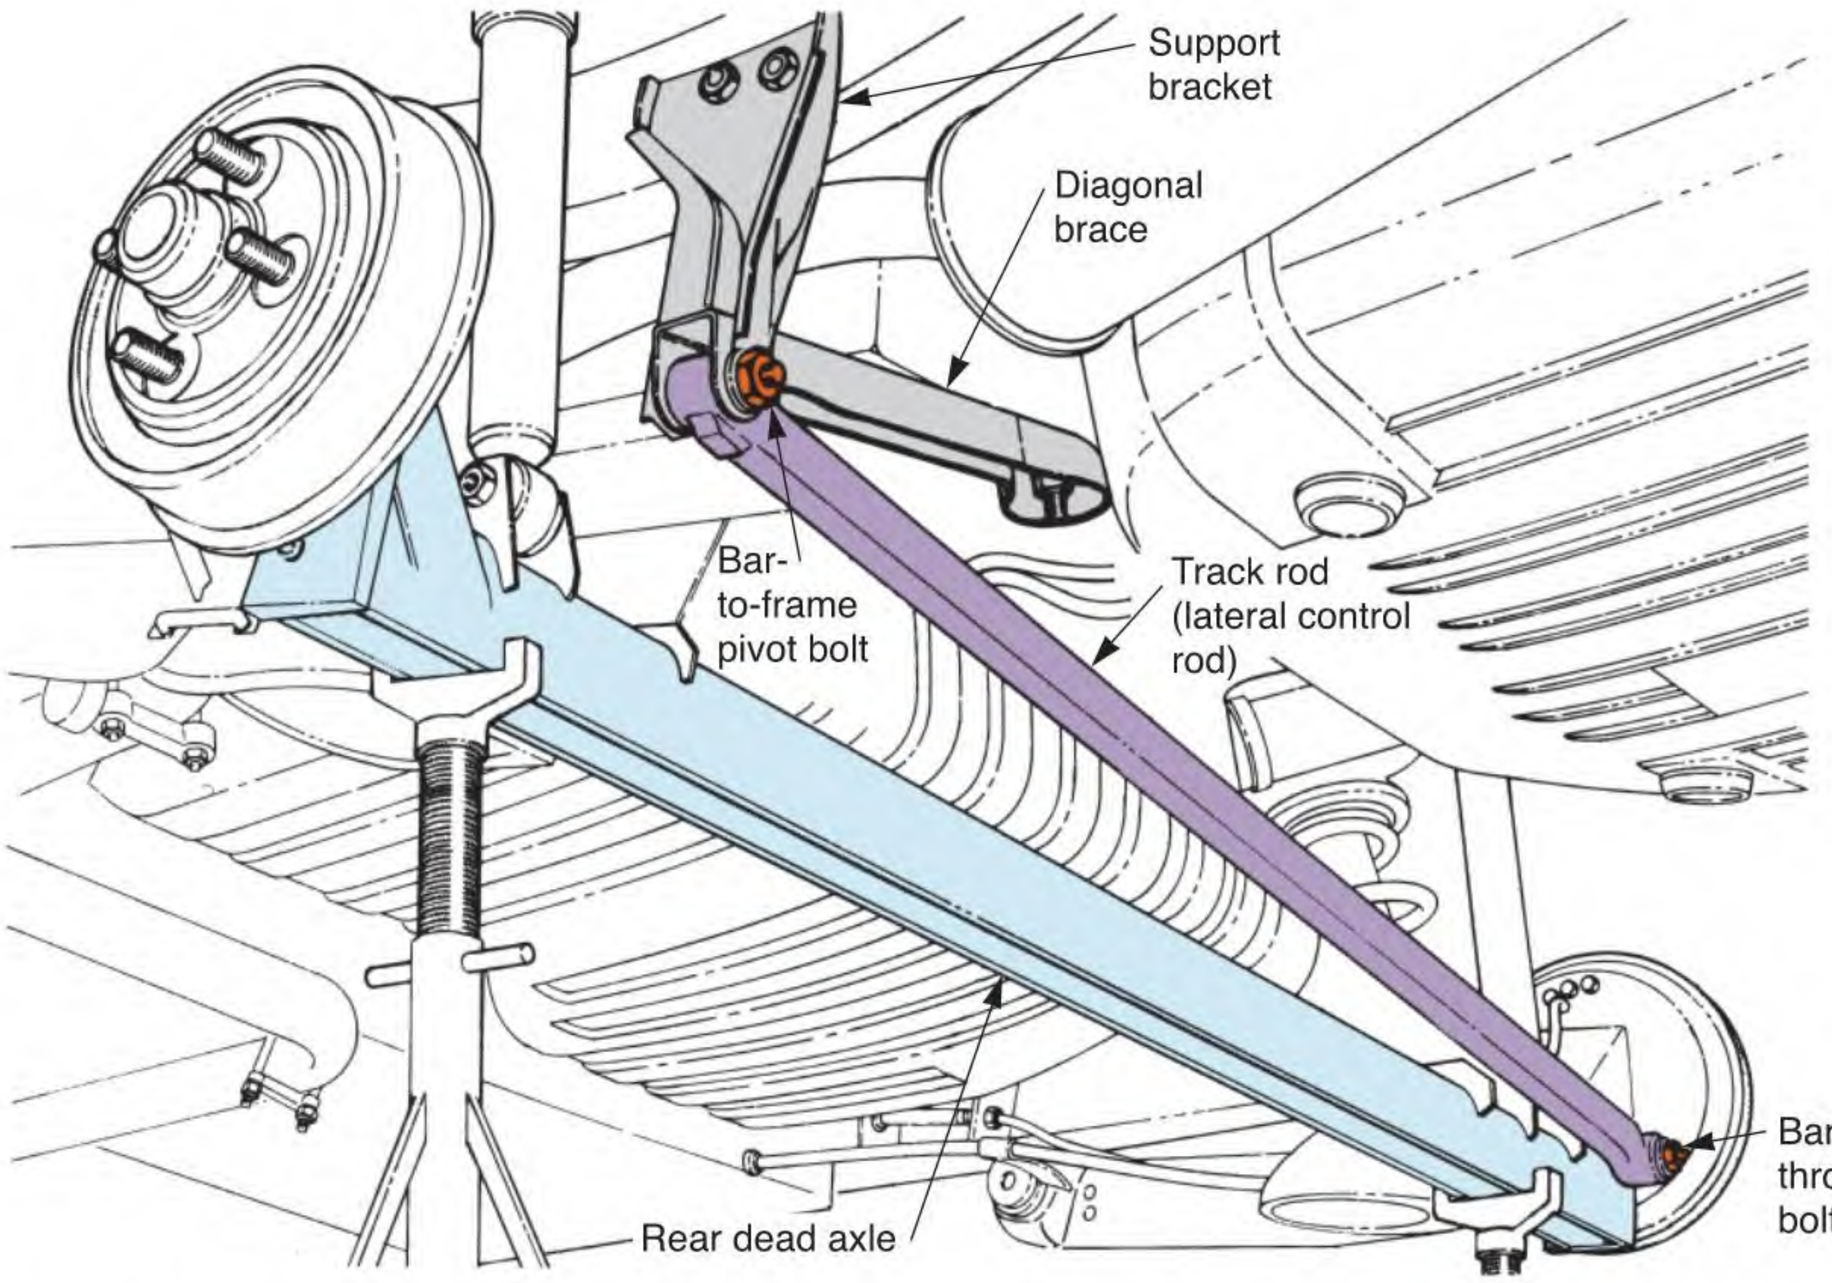
Figure 75-14. The sway bar attaches to both control arms. When the car rounds a corner, its body leans to one side. The sway bar bends, which lessens sway, or body lean, in turns.

Jounce Bumpers

Jounce bumpers are blocks of hard rubber that keep the suspension system parts from hitting the frame or body when the car hits large bumps or holes.

If you drive over a large hump in the road too quickly, you will hear the suspension arms hit the jounce bumpers with a loud bang or thud. This warns you that the tires are leaving the road surface.

Long-Short Arm Suspension



A ***long-short arm suspension*** uses control arms of different lengths to keep the tires from tilting with suspension action. The upper control arms are shorter than the lower control arms. See **Figure 75-16**.

If the control arms were the same length, the front tires would pivot outward at the top when the vehicle hits a bump. This would cause undue tire scuffing and wear.

Torsion Bar Suspension

A ***torsion bar suspension*** is a suspension system that contains torsion bar springs instead of coil springs. Most torsion bar suspensions allow easy adjustment of ***curb height*** (distance from the road up to a specific point on the car). By turning an adjustment bolt, you can increase or decrease the tension on the torsion bar. This either raises or lowers the frame and/or body of the vehicle.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 75-15. A track rod is commonly used on the rear axle to prevent side-to-side movement. Note how the rod connects to the frame and axle.

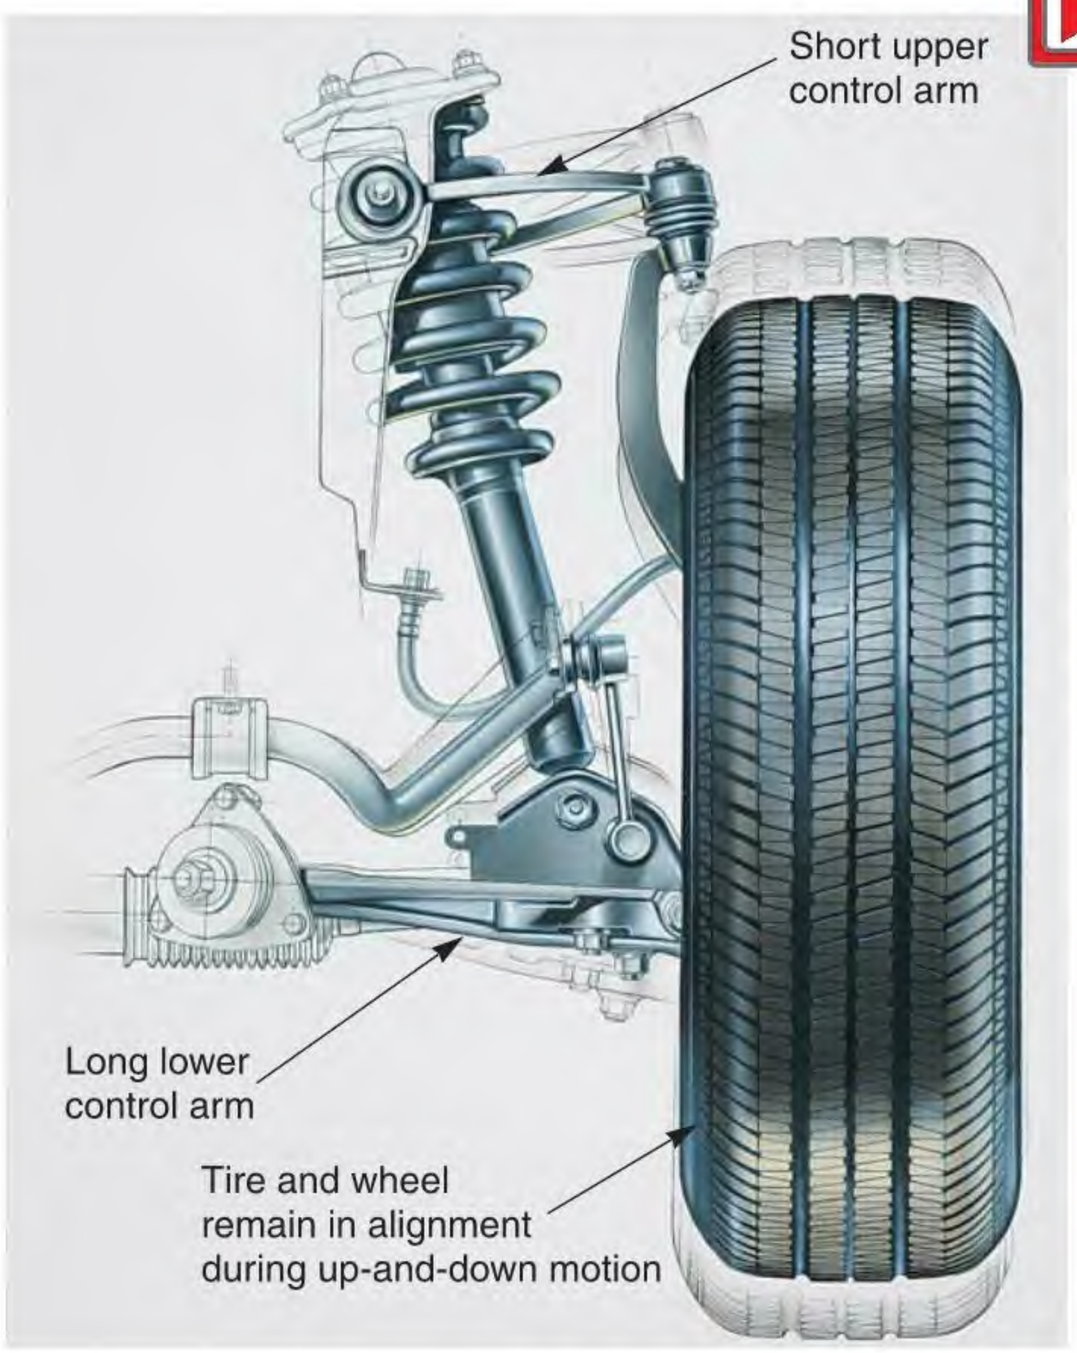
MacPherson Strut Suspension

A ***MacPherson strut suspension*** uses only *one* control arm and a *strut assembly* (spring, damper, and shock absorber unit) to support each wheel assembly, **Figure 75-17**. Note that the ***modified strut suspension*** has the coil spring mounted on top of the lower control arm, not around the strut.

A conventional lower control arm attaches to the frame and to the lower ball joint. The ball joint holds the control arm to the steering knuckle or bearing support. The top of the steering knuckle or bearing support is bolted to the strut assembly. The top of the strut is fastened to the reinforced body structure, **Figure 75-18**.

MacPherson strut suspension is the most common type of suspension found on late-model cars, and may be used on both the front and rear wheels. It reduces the number of parts in the suspension system, lowering the unsprung weight and smoothing the ride, **Figure 75-19**.

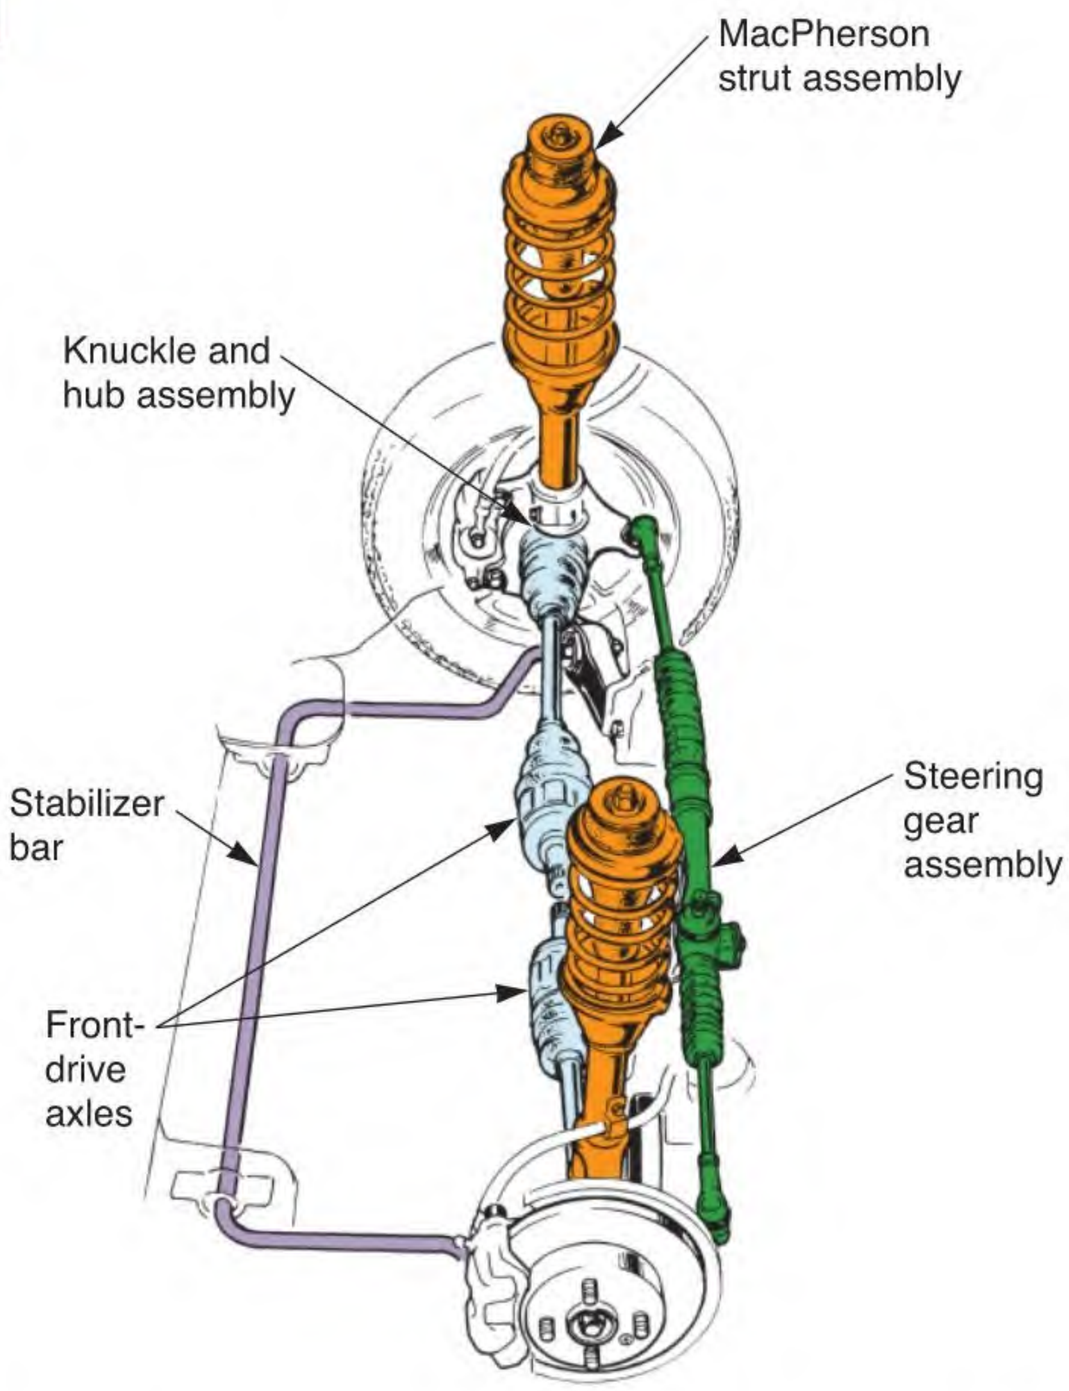
Pickup Truck Suspension Systems



Pickup trucks use numerous suspension system designs: long-short control arm, MacPherson strut, solid axle, and twin axle (or twin I-beam) suspension. The control arm and strut types are basically the same as those used on passenger cars, but are heavier and stronger. **Figure 75-20** shows a twin-axle, or twin I-beam, suspension.

A four-wheel-drive truck can have a solid axle housing and differential in the front. The steering knuckles are mounted on the axle housing so that they will swivel left or right for cornering.

Rear Suspension Systems



Rear suspension systems are similar to front suspension systems, but they normally do *not* provide for steering. Look at **Figure 75-21**. With a rear-wheel-drive vehicle, the rear axle housing may be solid, resulting in nonindependent suspension. However,

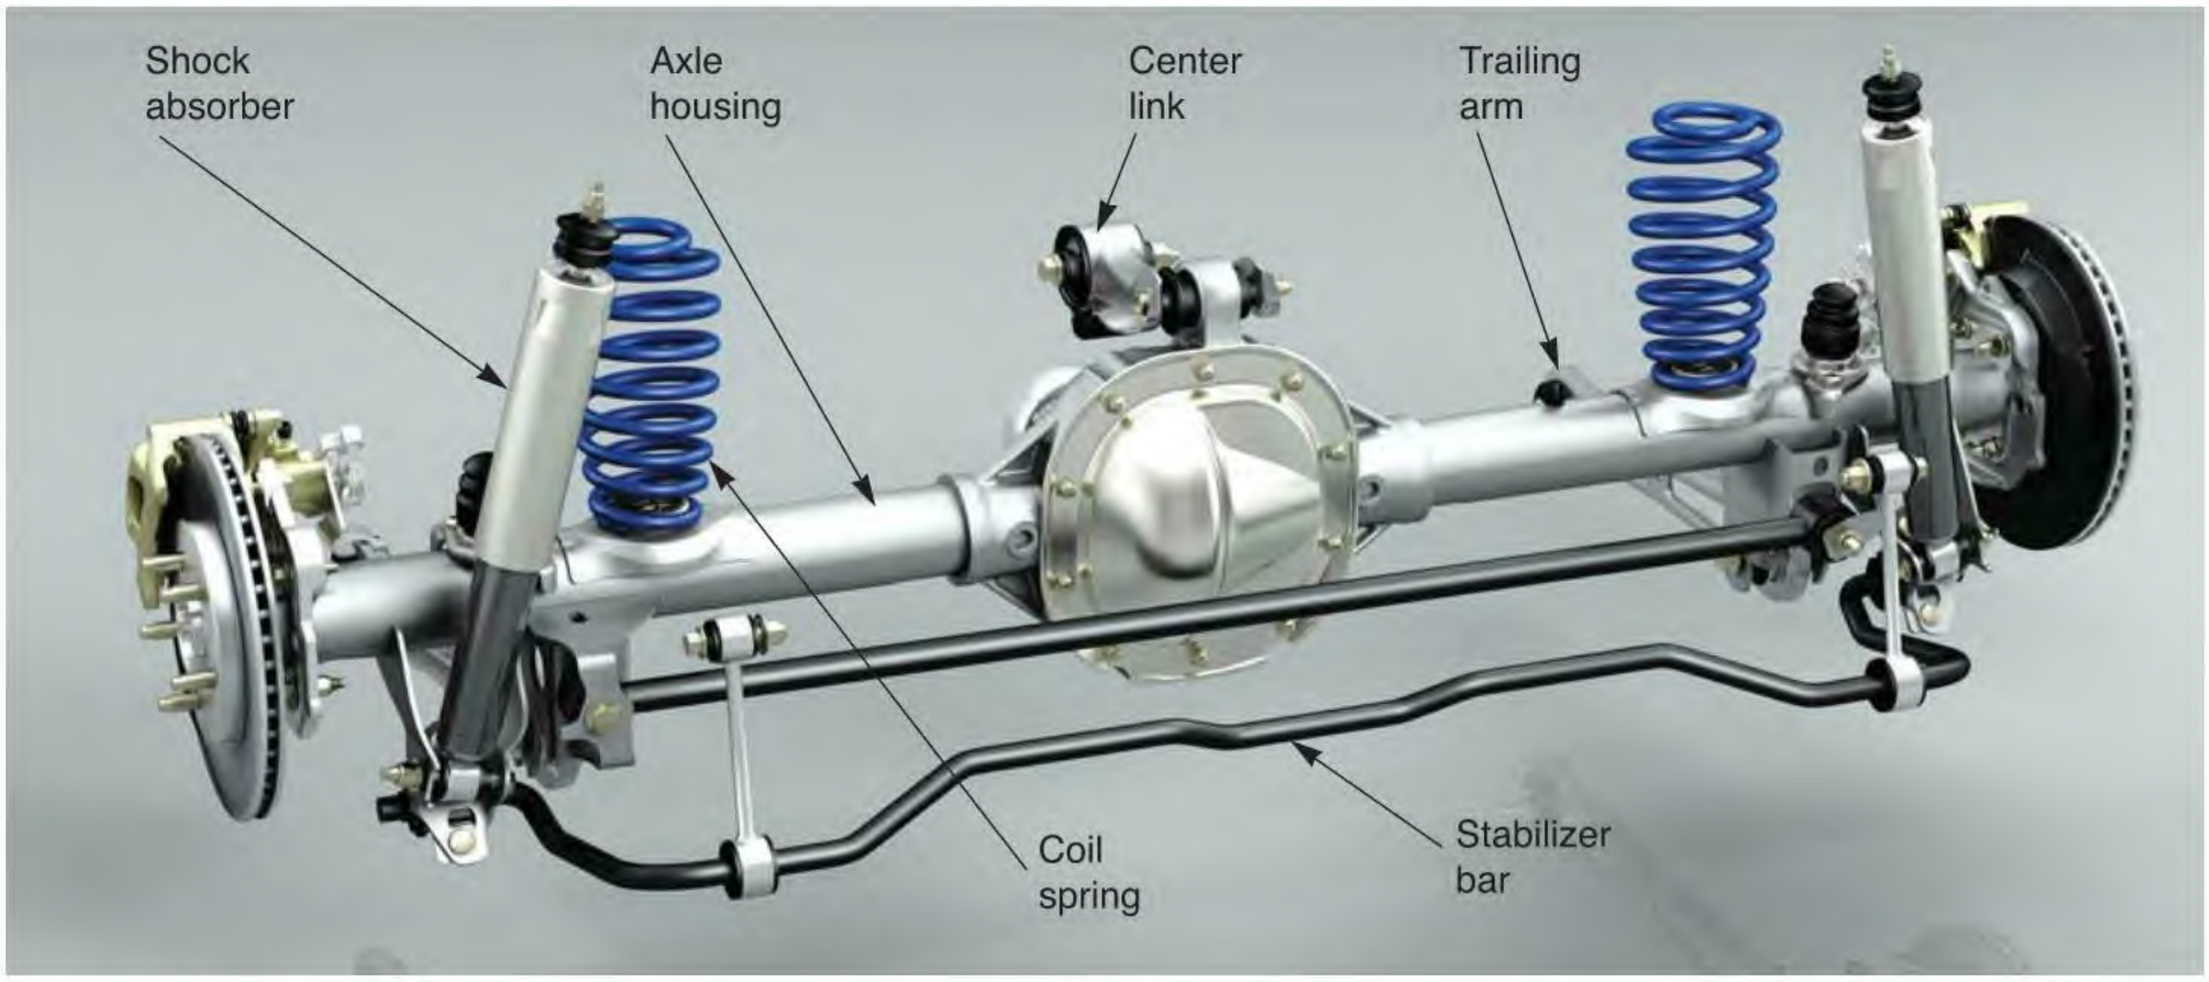
Ford

Figure 75-20. Twin I-beam suspension is used on a few pickup trucks.

rear swing axles and independent suspension can also be used.



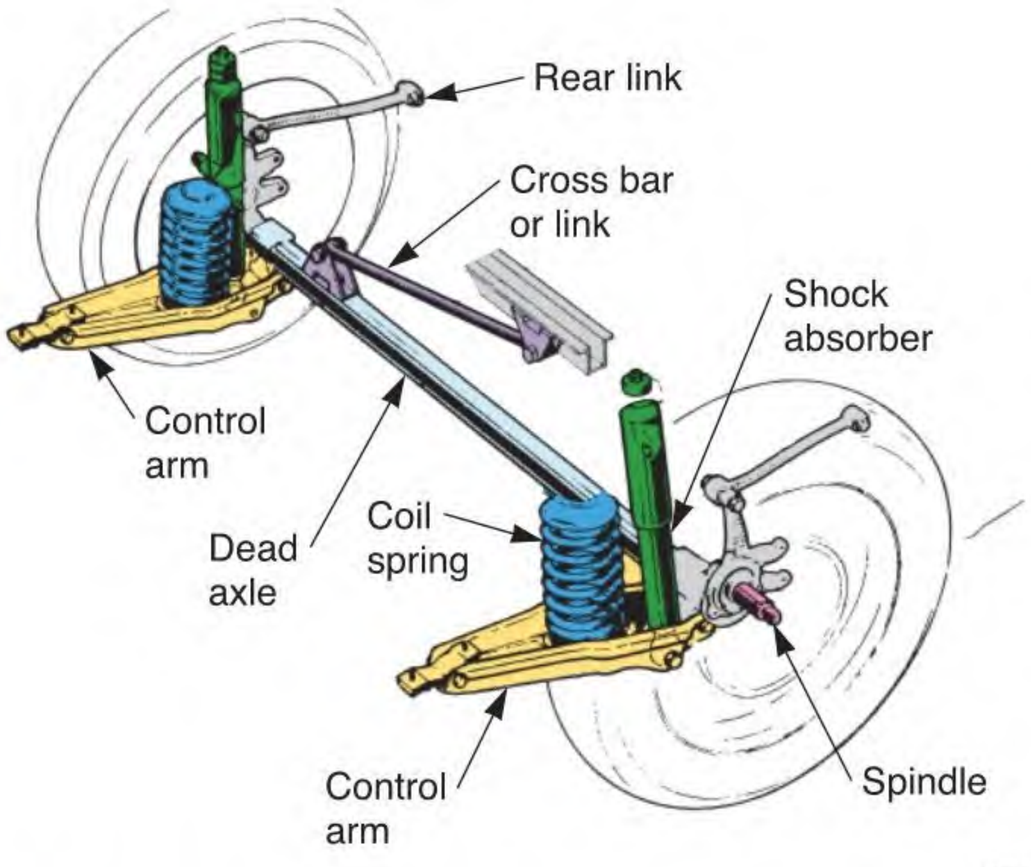
Dead Axle

A ***dead axle*** is a term used to describe a solid rear axle on a front-wheel-drive vehicle. Since the front wheels transfer driving power to the road, the rear axle is simply a straight, or solid, axle, **Figure 75-22**.

Semi-Independent Suspension

Semi-independent suspension means that the right and left wheels are partially independent of each other. This type of suspension uses a flexible axle. When one tire hits a bump, its control arm moves up. Since the axle can flex or twist, the effect on the other tire is minimized.

Copyright Goodheart-Willcox Co., Inc.



Ford

Figure 75-21. Solid axle housing rear suspension for rear-wheel-drive vehicle. Solid rear axles are commonly used on pickup trucks and full-size cargo vans. Study the parts.

Independent Rear Suspension

Most new cars use independent rear suspension to improve handling and ride quality. As with front suspension, independent suspension increases ride smoothness and cornering capabilities. Variations of this modern suspension design can be used with either a front- or rear-wheel-drive vehicle. Refer to **Figures 75-23** through **75-25**.

Saab

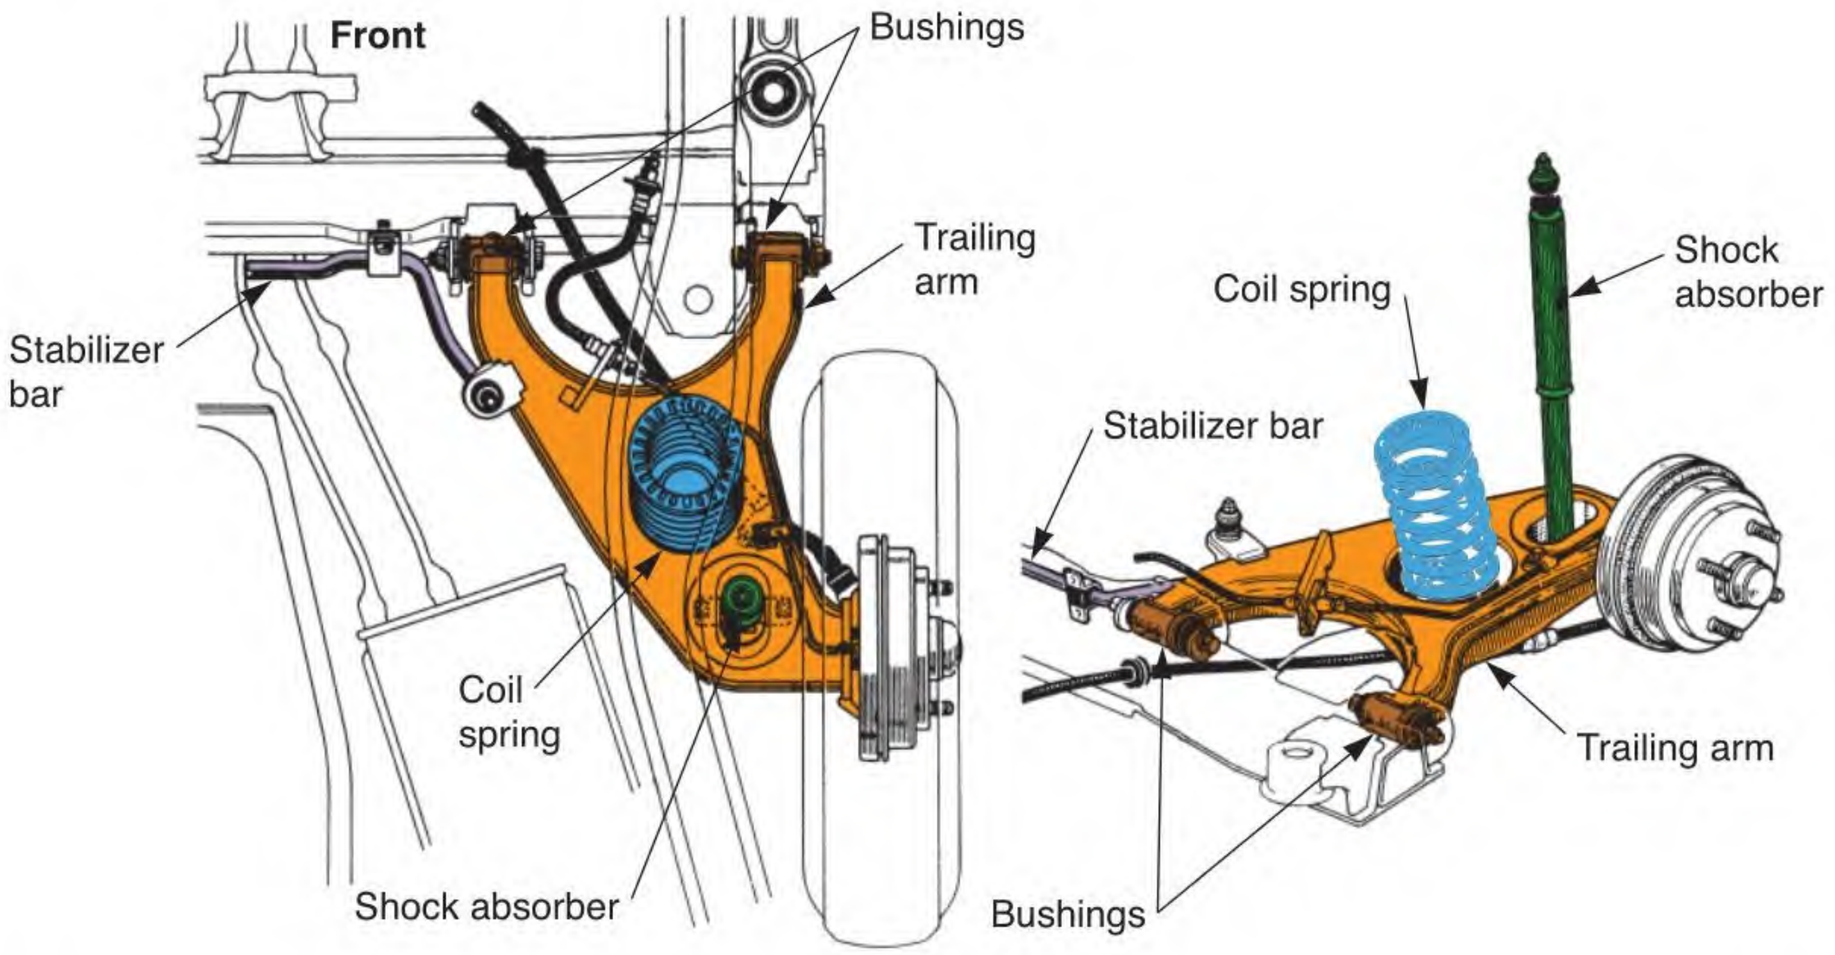
Figure 75-22. The term *dead axle* generally refers to a solid axle that does not drive wheels.

Suspension Leveling Systems

A ***suspension leveling system*** is used to maintain the ride height and vehicle ***attitude*** (height ratio between front and rear of body) with changes in the amount or distribution of weight in the car. For example, if weight is added in the trunk, the suspension leveling system keeps the springs from compressing and lowering the body height.

There are two classifications of suspension leveling systems: manual and automatic.

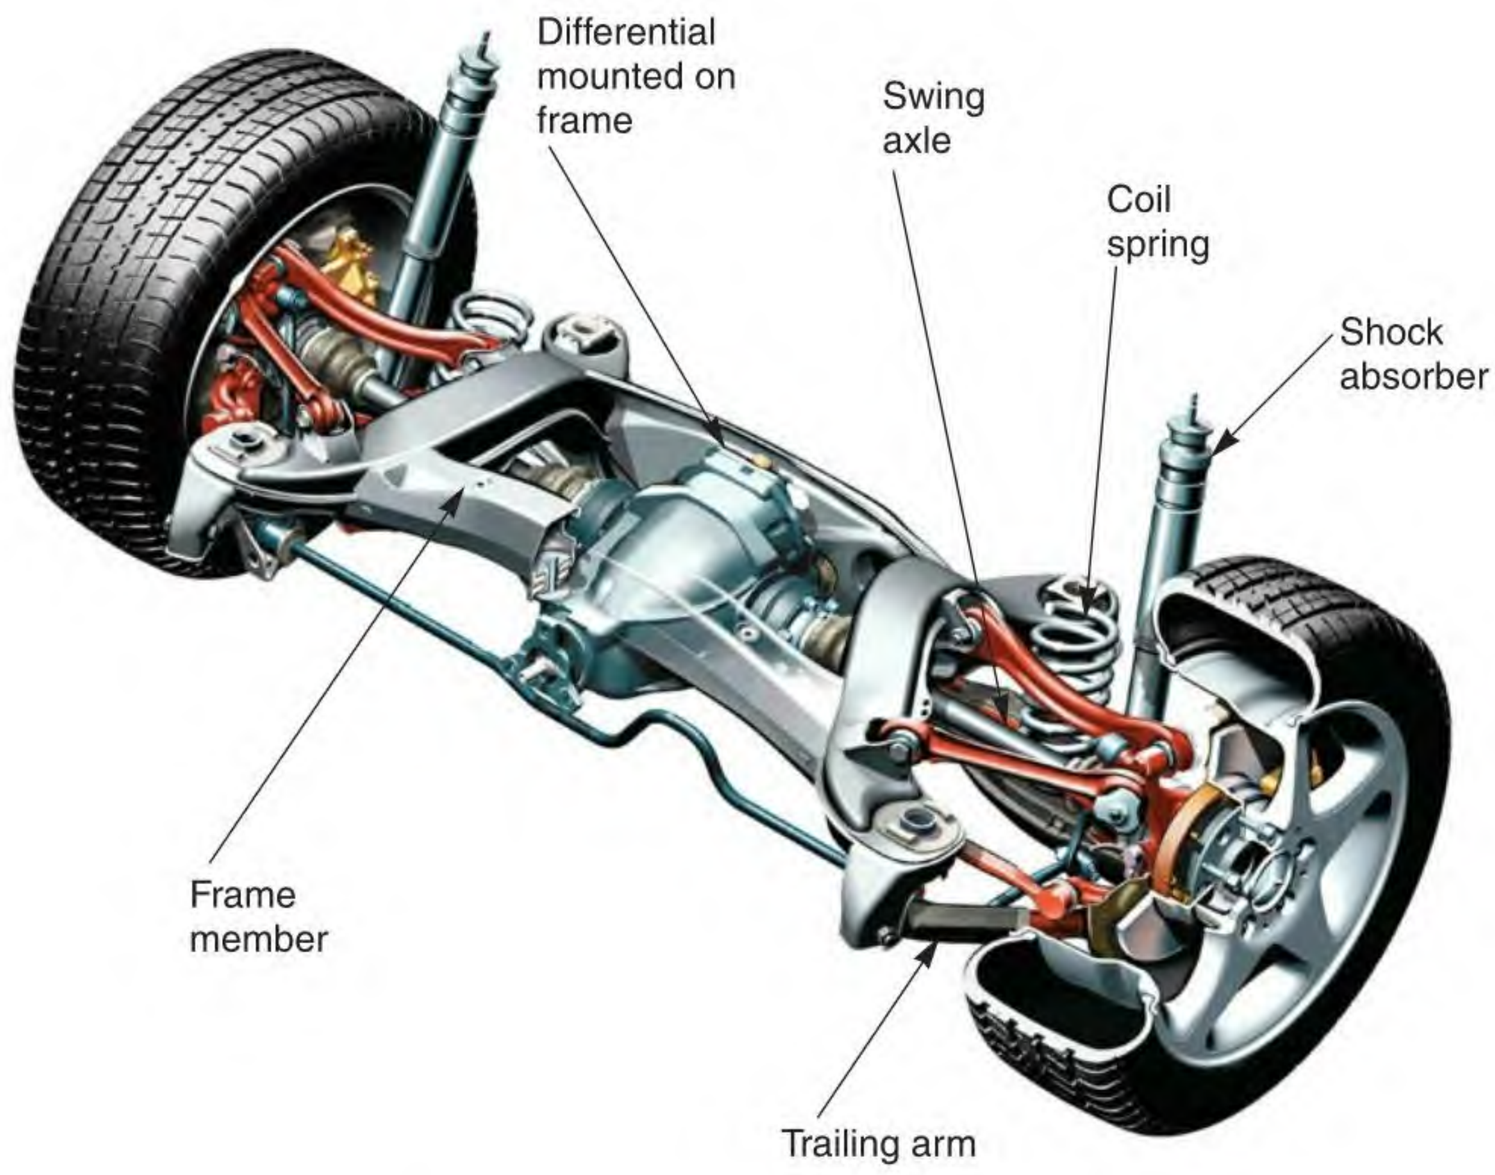
Manual Suspension Leveling System



A ***manual suspension leveling system*** uses air shocks and an electric compressor to counteract changes in passenger and luggage weight. A manual switch is used to activate the compressor to alter air shock pressure and body height.

Automatic Suspension Leveling System

Automatic suspension leveling systems use air shocks or air springs, height sensors, and a compressor to maintain curb height. System designs vary. Refer to **Figure 75-26**.



Most automatic suspension leveling systems use air shock absorbers. See **Figure 75-27**. A height sensor is connected to the frame and to the axle housing.

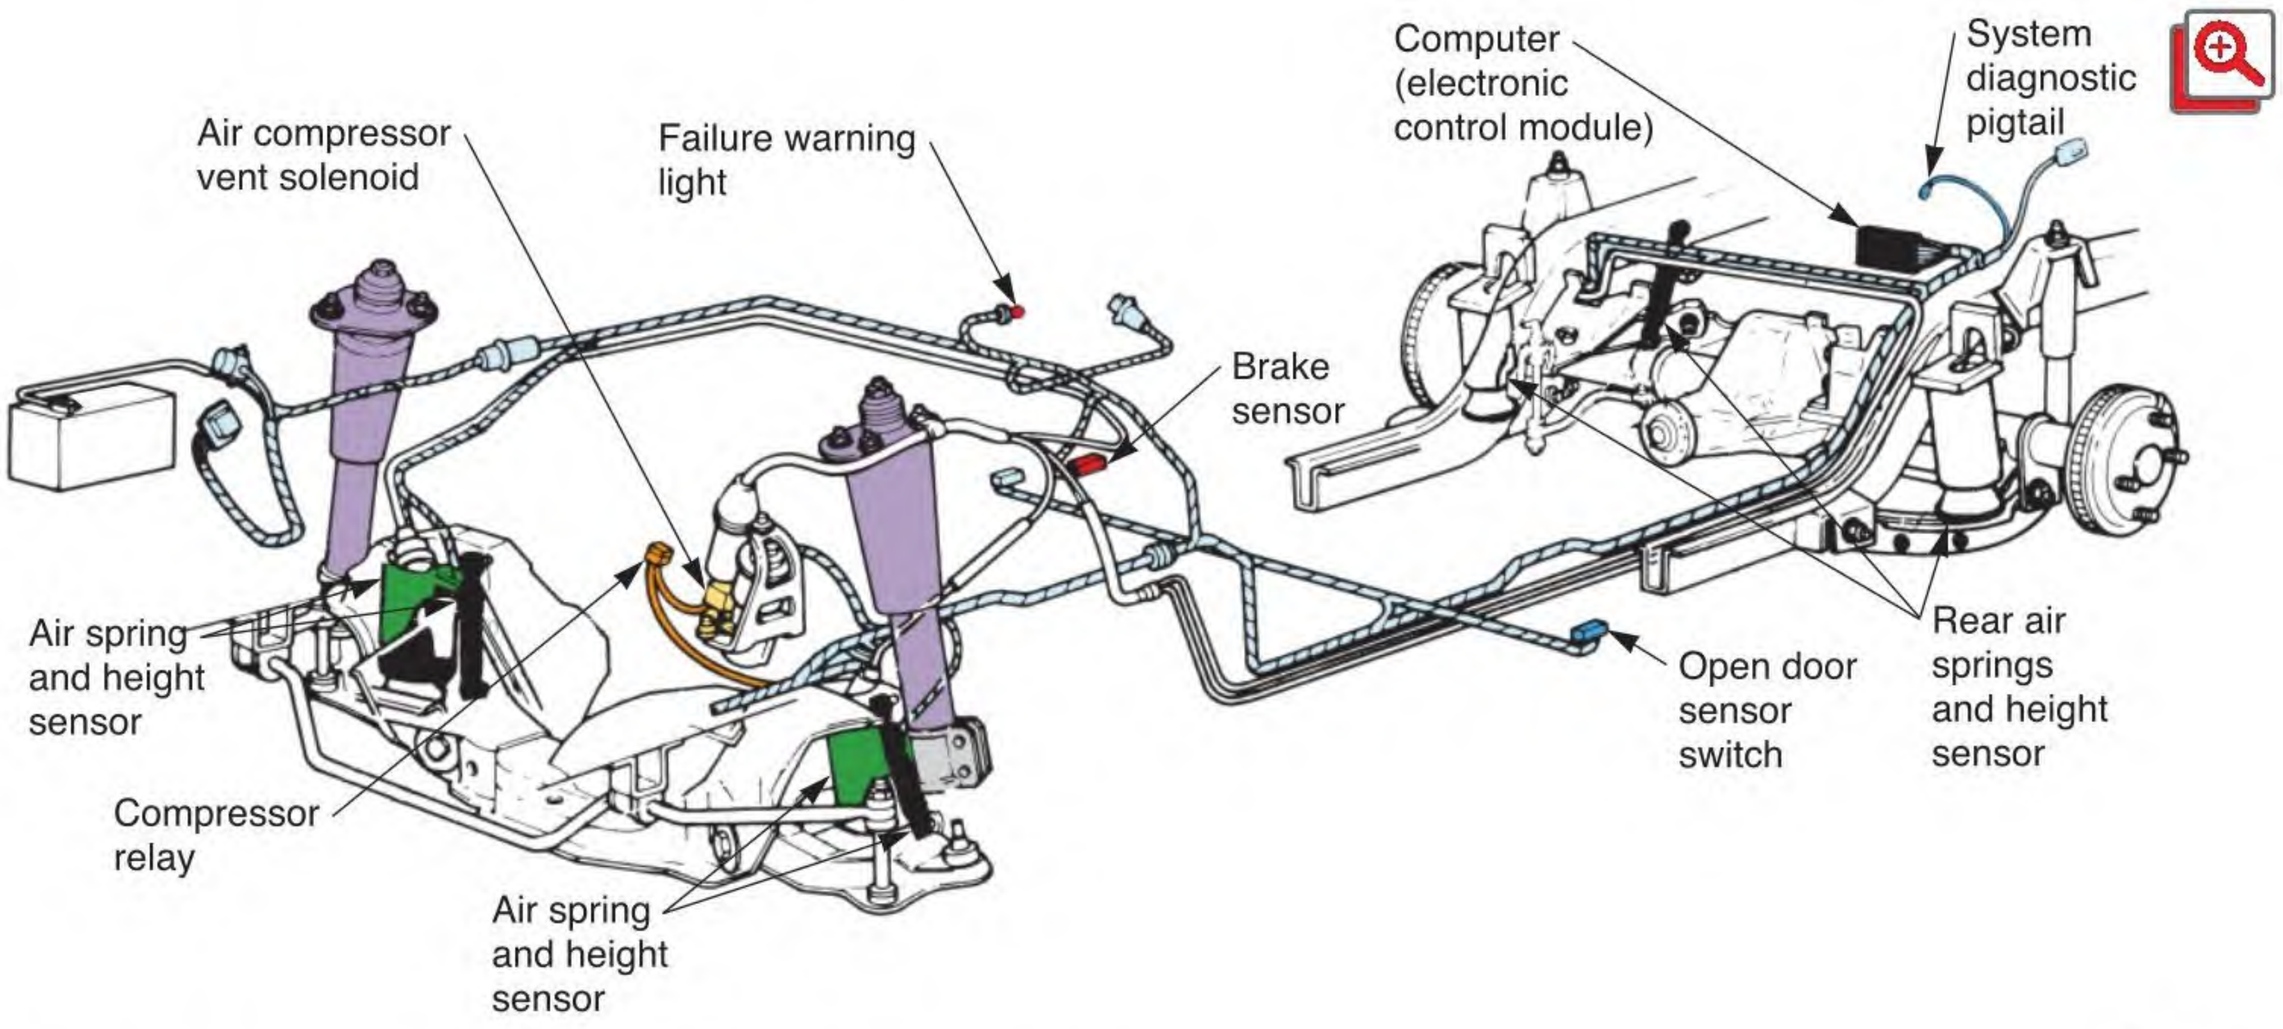
Honda

Figure 75-25. This double wishbone suspension system is a long-short arm design. The lower trailing arms have been lightened by forming holes in them. This improves ride smoothness.

Chrysler

Figure 75-26. Major parts of suspension leveling system. Basically, the height sensor triggers the air pump. The air pump operates the air shocks to maintain the correct vehicle height.

If load changes, the sensor can turn the compressor on, increasing pressure in the air shocks to counteract the increased load. It can also bleed air out of the shocks to counteract decreased load.



Electronic Height Control System

An ***electronic height control system*** uses height sensors and an electronic control module to control the operation of a small electric air compressor, which maintains the correct ride height. This system is used on the rear of the car to compensate for loads placed in the trunk or for the weight of passengers in the back-seat.

The main parts of an electronic height control system include:

- ***Height sensor***—The height sensor is a lever-operated switch that reacts to changes in body height and suspension movement.
- ***Compressor assembly***—The compressor assembly is a motor-powered air pump that produces pressure for the system.

Copyright Goodheart-Willcox Co., Inc.

Ford

Figure 75-27. Suspension leveling system using air springs. Study the parts.

- ***Pressure lines***—Pressure lines are air hoses that connect the compressor to the air shock absorbers.
- ***Air shocks***—These air-filled shock absorbers act on the suspension system to alter ride height.
- ***Sensor link***—A sensor link is a linkage rod that connects the height sensor to the suspension.
- ***Solenoid valve***—A solenoid valve is a solenoid-operated air valve that can release air pressure from the system.
- ***Suspension control module***—The suspension control module is an ECM, or small computer, that operates the solenoid valve by responding to signals from the height sensor.

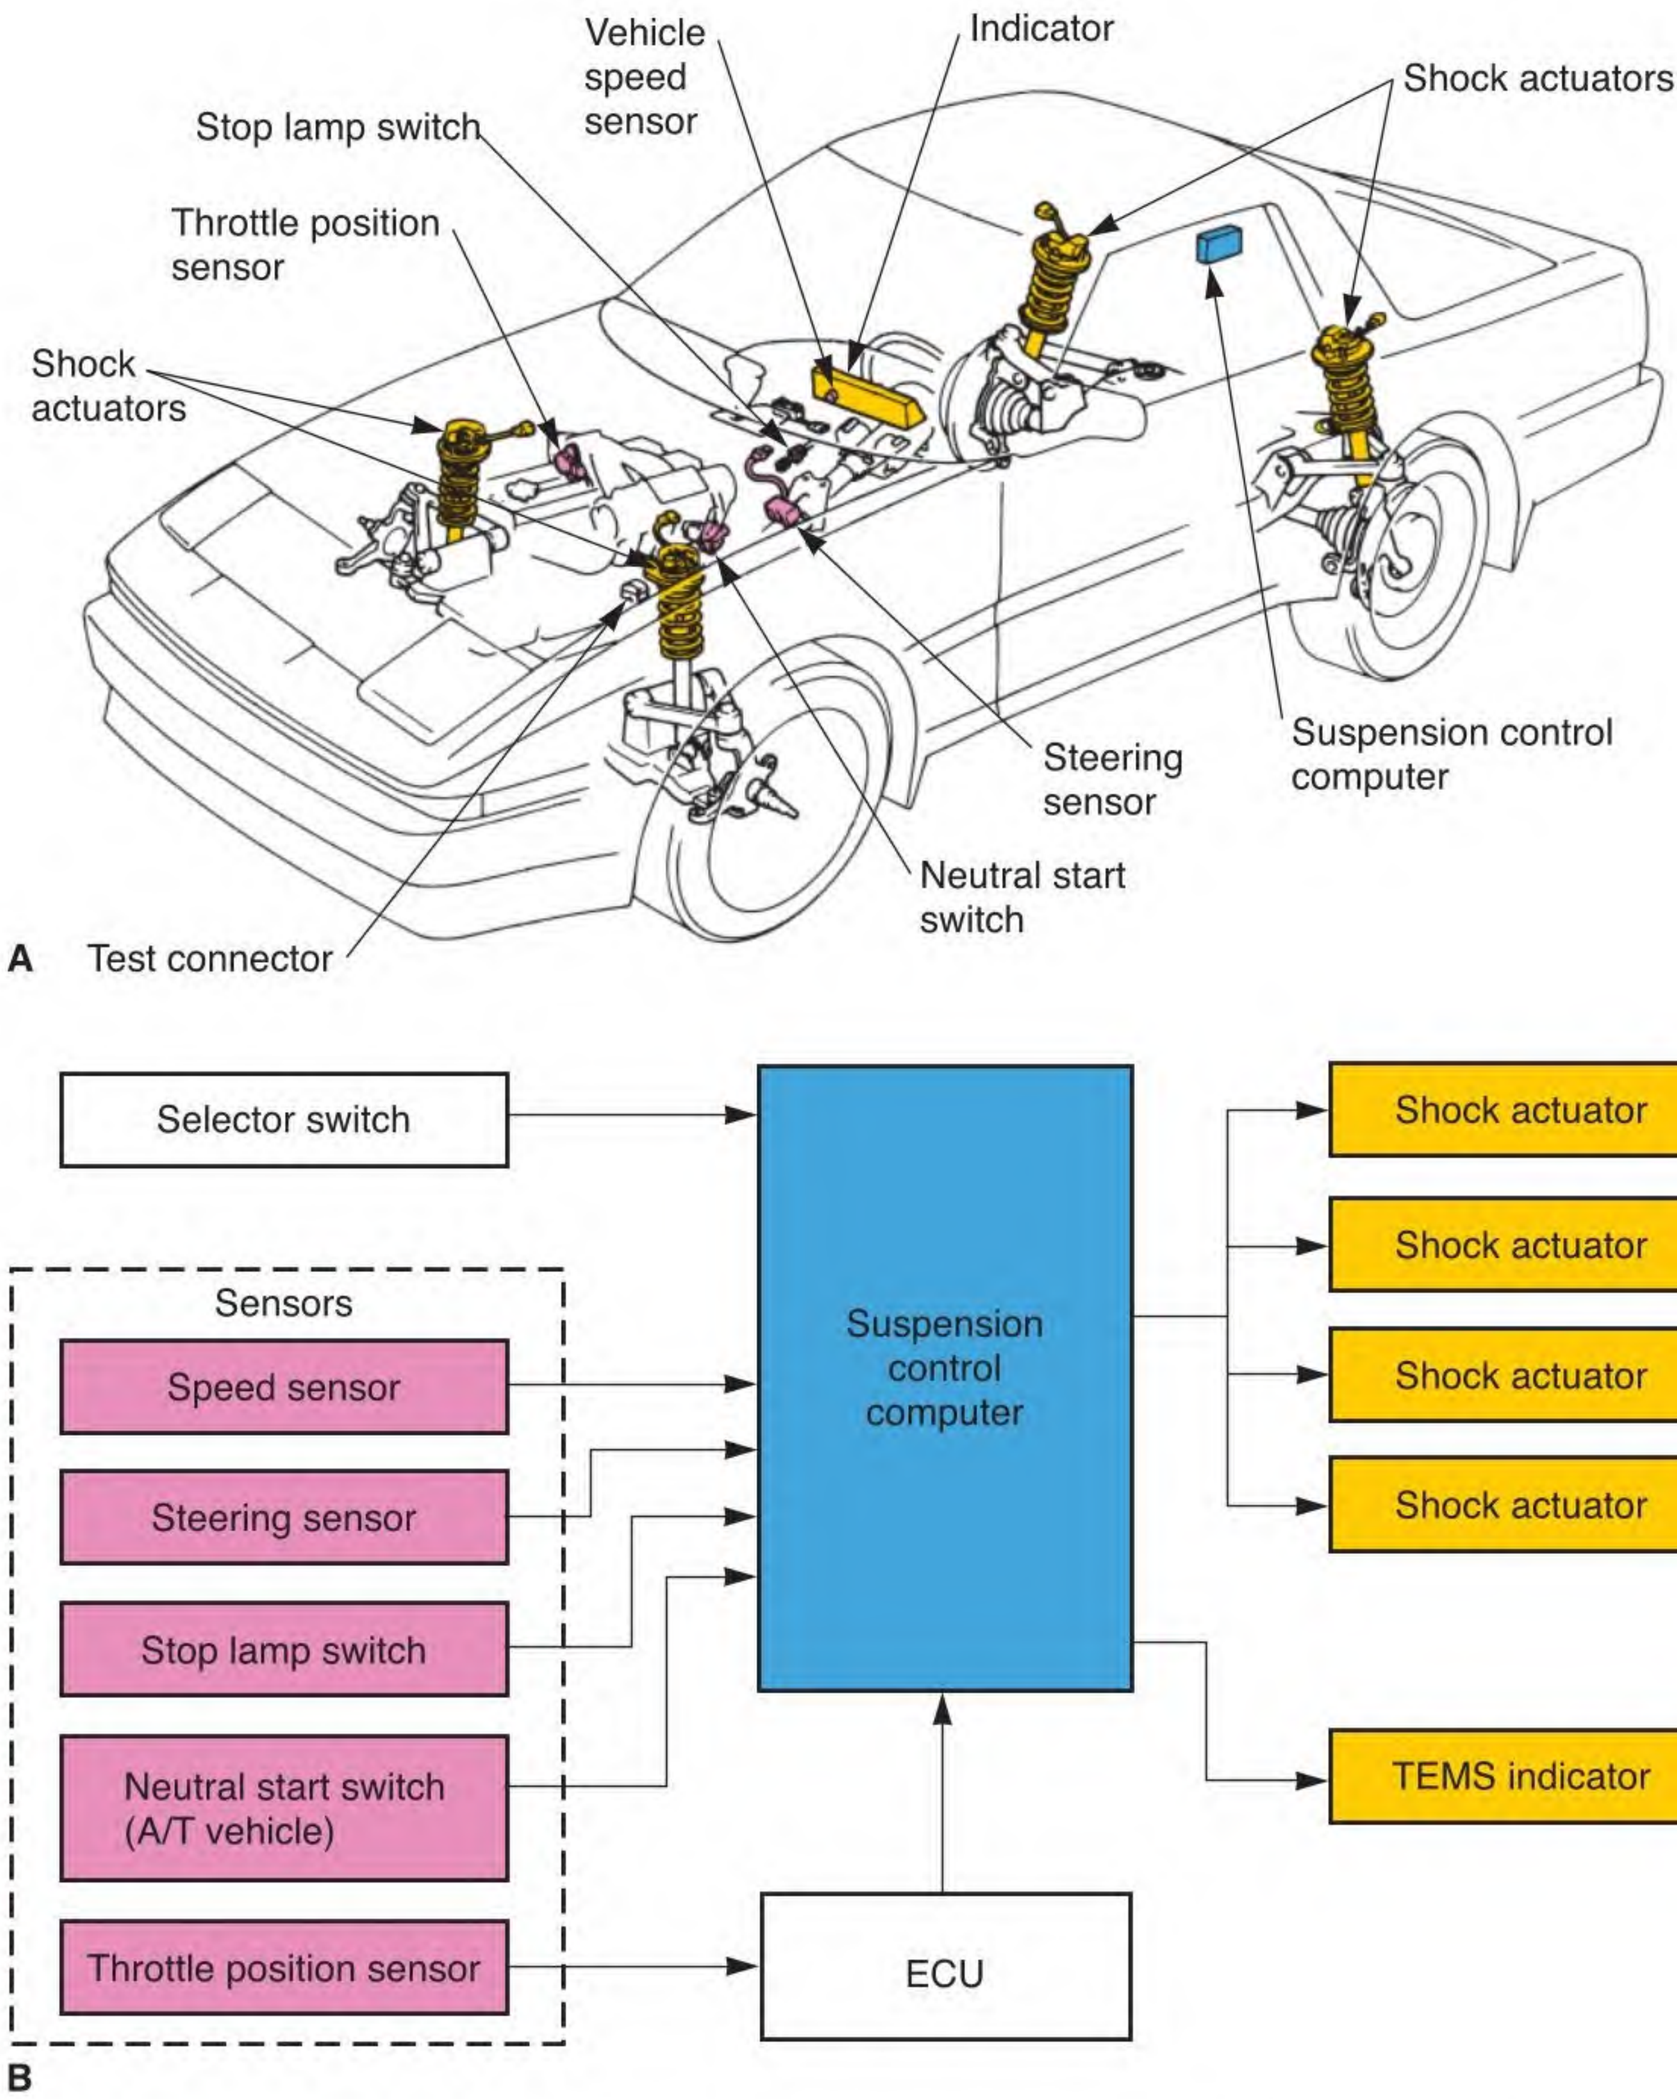
When the car body is at a normal riding height, the electronic height control system is off. Air pressure in the shocks is adequate to keep the car body at the correct distance from the road surface. The height sensor does not feed current to the control module.

If the trunk is loaded with heavy luggage, the weight of the luggage compresses the rear air shocks. This lowers the ride height. When the car is started, the height sensor is activated by the action of the sensor link and the sensor switch closes. The signal from the height sensor prompts the suspension control module to energize the compressor. The compressor pumps more air pressure into the rear shock absorbers, extending the shocks and raising the car body.

When the specific ride height is reached, the height sensor switch opens to turn off the compressor. This restores the vehicle to the correct ride height, even with extra weight in the trunk.

When the weight is removed from the trunk, the car body will rise. The height sensor switch is then moved in the other direction by the link. This closes another set of contacts in the switch, energizing the pressure release solenoid valve. Air pressure is then expelled from the rear shocks until the body drops down to the correct ride height.

Electronic Suspension System

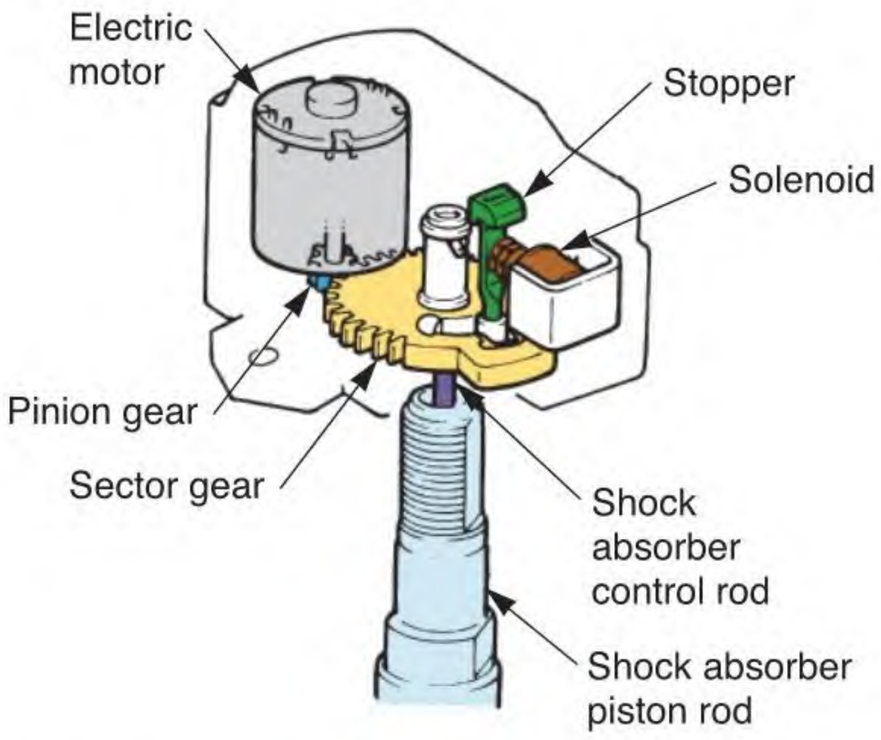


An ***electronic suspension system*** uses various sensors, a computer, and shock absorber actuators to control ride stiffness. It is designed to increase comfort and safety by matching suspension system action to driving conditions, **Figure 75-28**.

The major components of a typical electronic shock absorber system include:

- ***Steering sensor***—The steering sensor detects steering wheel rotational direction and speed, and feeds data about vehicle direction to the computer.
- ***Brake sensor***—Usually, the brake light switch is used to report when the brakes are applied.

Copyright Goodheart-Willcox Co., Inc.



- ***Acceleration sensor***—Usually, the throttle position sensor and accelerator pedal sensor are used to detect when the car is accelerating rapidly.
- ***Mode switch***—This dash-mounted switch allows the driver to choose the desired shock action or stiffness, and sometimes ride height.
- ***Electronic control module***—This small computer uses sensor inputs to control the shock actuators.
- ***Shock actuators***—Shock actuators are solenoid-operated valves that control fluid flow inside the shock absorbers. See **Figure 75-29**.

Toyota

Figure 75-28. This electronic suspension system automatically adjusts shock stiffness to match driving and road conditions. A—Note the major components of an electronic suspension system. B—This block diagram shows how the sensors feed data to the suspension control computer. The computer then energizes the shock actuators to modify ride stiffness and shock action.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 75-29. This shock actuator uses a small electric motor and a solenoid to move the shock piston rod in and out. Piston rod movement alters shock dampening action.

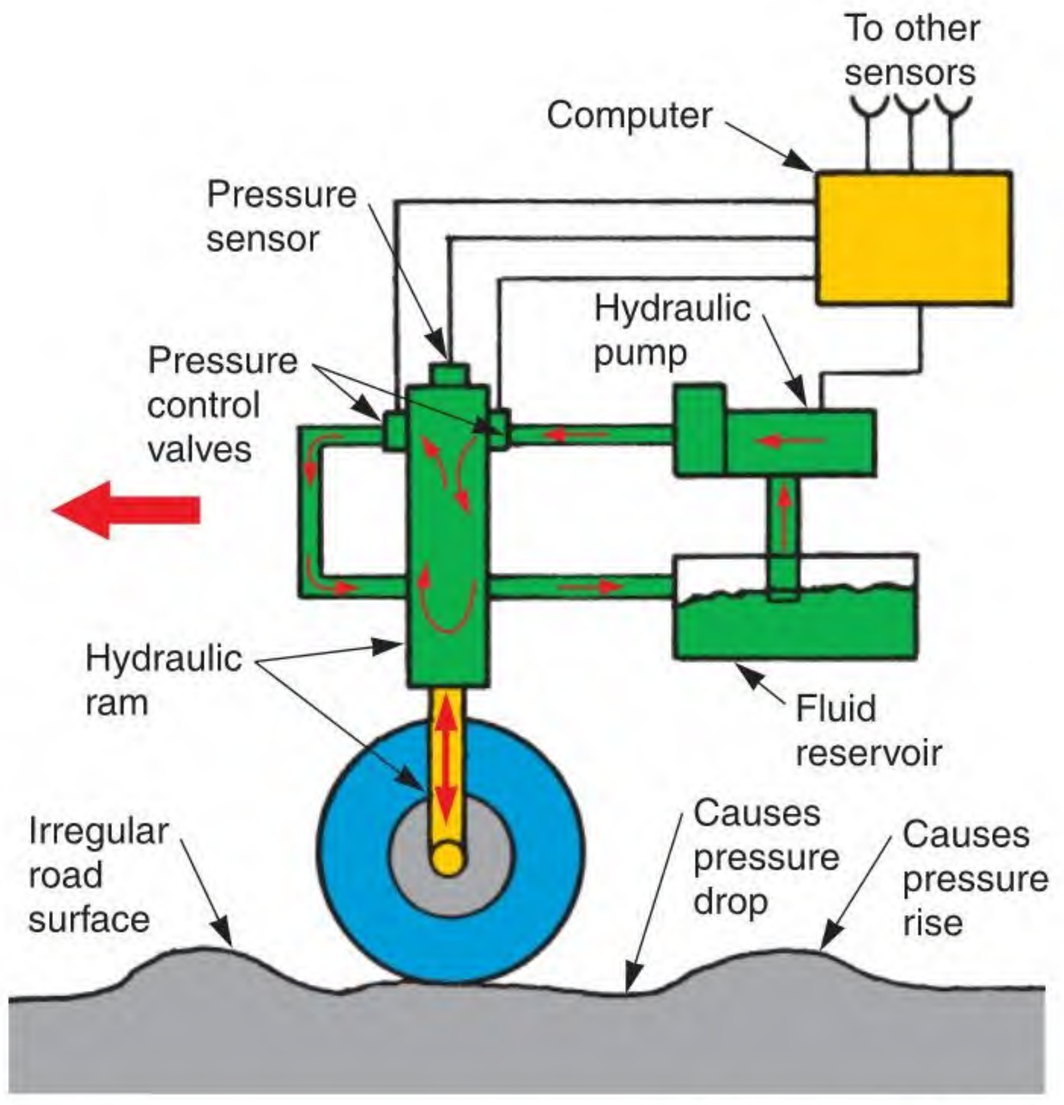
If a car is being driven on curving country roads, the driver might switch to a stiff setting with the mode switch. The electronic control module would then energize the shock actuators to close or restrict the shock absorber valves to increase dampening action. This stiffens the ride and makes the car corner better.

If driving on a rough highway, the mode switch might be moved to a soft setting. The electronic control module would then energize the shock actuators to open the valves more. This softens the ride by allowing easier shock movement.

Under hard braking, the brake sensor could send a signal to the electronic control module. The control module could then stiffen the shocks to prevent the front of the car from diving.

With rapid turning or cornering, the steering sensor could also signal the electronic control module. The module could then stiffen the shocks to prevent excess body roll, or lean, in turns.

Some cars use air shocks or air bags instead of hydraulic shock absorbers. The operation of these systems is similar.



One type of electronic shock absorber system uses a sonar sensor to detect changes in road conditions. The sensor is mounted at the front of the vehicle and produces sound waves. These waves bounce off the road and back into the sensor. The sensor's output signal is determined by the amount of time needed for the waves to strike the road surface and bounce back. The computer uses the output signals from the sonar sensor to determine proper ride stiffness. If, for example, there is a dip in the road, the sound waves take longer to return to the sensor. This causes the sensor to modify its output signal. The computer analyzes the sensor's output signals and adjusts shock action as necessary.

Active Suspension System

An ***active suspension system*** uses computer-controlled hydraulic rams instead of conventional springs and shock absorber actuators to control ride characteristics. A fully active suspension is called an "intelligent suspension" because a computer controls the hydraulic system.

The hydraulic rams support the weight of the car and react to the road surface and driving conditions. An active suspension system is similar to an electronic shock absorber system, but it is more complex. Refer to **Figure 75-30**.

Basically, pressure sensors on each hydraulic ram provide the main control for the system. The sensors react to suspension system movement and send signals to the computer. The computer can then extend or retract each ram to match the road surface. A hydraulic pump provides pressure to operate the rams. Pressure control valves are located on each ram. By opening and closing these valves, the computer can

Goodheart-Willcox Publisher

Figure 75-30. This simplified illustration shows the major components of an active suspension system.

Copyright Goodheart-Willcox Co., Inc.

adjust the pressure of the rams and the resulting height of each corner of the vehicle.

For example, if one side of the vehicle travels over a bump in the road, the pressure sensors can instantly detect a rise in pressure inside the ram as the tire and wheel push up on the suspension and the hydraulic ram. Instead of the vehicle's body rising with spring action, the computer can release enough ram pressure to allow the suspension to move up over the bump without causing body movement. Then, as the tire travels back down over the bump, the sensor detects a pressure drop in the ram and the computer increases ram pressure so the tire follows the road surface.

The active suspension system can make a car feel as if it is floating on a cushion of air. It can, theoretically, eliminate most body movement as the car travels over small dips and bumps in the road. It can also help keep the body level under various driving conditions. During hard braking, the active suspension system can keep the front of the body from diving and the rear from rising, thus improving action.

In turns, the active suspension system's ability to prevent body roll (lean) can make the car stay level to increase cornering ability. It can tilt the vehicle's body against a turn to improve handling. It can also be used to lower the body for highway driving aerodynamics and to raise the body for added ground clearance during city driving.

Many auto manufacturers are experimenting with active suspension systems of this type. We may see them in the future, at first on more exotic sports cars, but someday on everyday passenger cars.

In the Rearview Mirror

The Ford Model-T was the first mass-produced passenger car. Affectionately called the "Tin Lizzie," this vehicle was first introduced in 1908. It was deemed "the car for the multitude" and was an instant success. Henry Ford developed this car and succeeded in building one of the largest automobile-manufacturing companies in the world. Not much more than a horse buggy with an engine, the Model-T drove like a log wagon and belched smoked like a steam engine.

Summary

- The suspension system allows the tires and wheels to move up and down over bumps and holes in the road surface.
- Chassis stiffness is a primary factor affecting how quiet and smooth a vehicle drives—the stiffer the chassis, the better.
- Independent suspension allows one wheel to move up and down with little effect on the other wheels.
- Nonindependent suspension has both the right and left wheels attached to the same solid axle.
- Lateral acceleration is the amount of side force a vehicle can handle in a sharp turn or curve before its tires lose traction and skid.
- Suspension system springs must jounce (compress) and rebound (extend) with bumps and holes in the road surface.
- A control arm holds the steering knuckle, bearing support, or axle housing in position as the wheel moves up and down.
- A strut rod fastens to the outer end of the lower control arm and to the frame. It keeps the control arm from swinging toward the rear or front of the vehicle.
- Ball joints (short for ball-and-socket joints) are connections that allow limited rotation in every direction.
- Shock absorbers limit spring oscillations (compression-extension movements) to smooth the vehicle's ride.
- A strut assembly consists of a shock absorber, a coil spring (most types), and an upper damper unit.
- A sway bar, also called stabilizer bar, is used to keep the body from leaning excessively in sharp turns.
- Jounce bumpers are blocks of hard rubber that keep the suspension system parts from hitting the frame or body when the vehicle hits large bumps or holes.
- A long-short arm suspension uses control arms of different lengths to keep the tires from tilting with suspension action.
- A MacPherson strut suspension uses only one control arm and a strut assembly (spring, damper,

Copyright Goodheart-Willcox Co., Inc.

and shock absorber unit) to support each wheel assembly.

- A dead axle is a term used to describe a solid rear axle on a front-wheel-drive vehicle.
- A suspension leveling system is used to maintain a constant vehicle attitude (height ratio between front and rear of body) as the amount or distribution of weight in the vehicle changes.
- To maintain correct ride height, an electronic height control system uses height sensors and an ECM to control the operation of a small electric air compressor.
- An electronic shock absorber system uses various vehicle sensors, an electronic control module, and shock absorber actuators to control ride stiffness.
- An active suspension system uses computer-controlled hydraulic rams instead of conventional suspension system springs and shock absorbers.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

acceleration sensor
active suspension system
adjustable shock absorbers
air shocks
air spring
attitude
automatic suspension leveling systems
ball joints
body dive
body roll
body squat
brake sensor
chassis hertz
chassis stiffness
coil spring
compressor assembly
control arm
control arm bushings
curb height
damper unit
dead axle
dust shield
electronic control module
electronic height control system
electronic suspension system
gas-charged shock absorbers
height sensor
independent suspension
insulators
jounce
jounce bumpers
lateral acceleration
lateral control rod
leaf spring
leaf spring windup
long-short arm suspension
lower spring seat
MacPherson strut suspension
manual suspension leveling system
mode switch
modified strut suspension
neutral steering
nonindependent suspension
oscillations
oversteer
pressure lines
rebound
rubber bumpers
rubber isolators
self-leveling shock absorber
semi-independent suspension
sensor link
shackle
shock absorber compression
shock absorber extension
shock absorbers
shock actuators
skidpad
solenoid valve
spring rate
sprung weight
stabilizer bar
steering sensor
strut assembly
strut bearing
strut rod
strut rod nut
strut shock absorber
suspension control module
suspension leveling system
suspension system
suspension system springs
sway bar
sway bar links
torsion bar
torsion bar suspension
track rod
travel
understeer
unsprung weight
upper spring seat
upper strut retainer

Activities

1. Create a visual presentation (a poster-size drawing, a model, or a multimedia presentation) of a suspension system. Explain to the class the function of each part in the system.
2. Examine actual shop vehicles to determine the type of suspension used at each wheel.
3. In a group, discuss the merits of different suspension systems. Which suspension systems would be better for a sports car versus a pickup truck?

Copyright Goodheart-Willcox Co., Inc.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List eight functions of a suspension system.
2. List and explain the six major parts of a suspension system.
3. _____ suspension allows one wheel to move up and down with a minimum effect on the other wheels.
4. The most common type of suspension system spring is the _____ spring.
   (A) leaf
   (B) coil
   (C) air
   (D) torsion
5. A(n) _____ fastens the rear of a leaf spring to the car frame.
6. Define the phrase "leaf spring windup."
7. How does a torsion bar work?
8. The _____ weight of a car is the weight of the parts *not* supported by the springs.
9. A strut rod is used to keep the steering knuckle from swiveling. True or False?
10. Why are ball joints needed?
11. Summarize the basic operation of a conventional shock absorber.
12. What is the advantage of gas-charged shocks?
13. List and explain the eleven major parts of a strut assembly.
14. The _____ is used to keep the car body from rolling or leaning excessively in turns or corners.
    (A) strut rod
    (B) jounce bumper
    (C) track rod
    (D) sway bar
15. Describe a MacPherson strut suspension.

ASE-Type Questions

1. Technician A says an automotive suspension system supports the weight of the engine. Technician B says an automotive suspension system supports the weight of the transmission. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. All of the following are functions of an automotive suspension system, *except:*
   (A) helps provide a smooth ride for passengers.
   (B) keeps tires in firm contact with the road.
   (C) allows the front wheels to turn from side to side for steering.
   (D) allows the body to tilt when heavily loaded.
3. Technician A says an automotive suspension system works with the steering system to help keep the wheels in correct alignment. Technician B says an automotive suspension system works independently of the steering system and has no effect on wheel alignment. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. All of the following are basic components of an automotive suspension system, *except:*
   (A) control arm.
   (B) steering knuckle.
   (C) internal control shaft.
   (D) shock absorber.
5. Technician A says a suspension system's control arm fastens the steering knuckle to the shock absorber. Technician B says the control arm fastens the steering knuckle to the frame. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says a ball joint allows control arm movement. Technician B says a ball joint allows steering knuckle movement. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

7. Technician A says the control arm bushing allows the suspension system control arm to swing up and down on the vehicle frame. Technician B says the control arm bushing allows the control arm to move from side to side on the suspension system damper. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says that in an independent suspension system, movement of one wheel does not cause direct movement of the wheel on the opposite side of the vehicle. Technician B says that in a nonindependent suspension system, movement of one wheel does not cause direct movement of the other wheel on the opposite side of the vehicle. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says an independent suspension system has both the right and left wheels attached to the same solid axle. Technician B says a nonindependent suspension system has both the right and left wheels attached to the same solid axle. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says a coil spring is the most common spring used on modern automotive suspension systems. Technician B says a leaf spring is the most common spring used on modern automotive suspension systems. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
11. Technician A says coil springs are used on either the front or the rear of an automobile. Technician B says coil springs are only used on the front of an automobile. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
12. Technician A says a torsion bar fastens to the vehicle's frame. Technician B says a torsion bar fastens to the suspension system control arm. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Chapter 76
Suspension System Diagnosis and Repair

After studying this chapter, you will be able to:

- Diagnose problems relating to a suspension system.
- Replace shock absorbers and ball joints.
- Describe the removal and replacement of springs.
- Replace control arm bushings.
- Service a strut assembly.
- Use safe work procedures while repairing suspension systems.
- Diagnose and repair electronically-controlled suspension systems.
- Correctly answer ASE certification test questions about the diagnosis and repair of suspension systems.

A suspension system takes a tremendous pounding during normal vehicle operation as it supports the weight of a vehicle going over millions of road surface irregularities. Bumps and potholes in the road cause constant movement, fatigue, and wear of shock absorbers, ball joints, bushings, springs, and other parts. After prolonged use, major repairs may be needed to restore the suspension system to its original condition.

This chapter covers the most common procedures for diagnosing and repairing suspension system problems. You will learn how to properly inspect, remove, and replace suspension parts using specialized suspension system tools. You will also learn a few tricks of the trade for finding worn suspension parts.

Suspension System Diagnosis

Suspension system problems usually show up as:

- Abnormal noises—These noises include pops, squeaks, and clunks from suspension parts.
- Tire wear—Worn suspension system parts allow the wheels to go out of alignment.
- Steering wheel pull—Part wear and incorrect wheel alignment make the vehicle wander or veer to one side of the road.
- Front end shimmy—Side-to-side vibration of the front wheels is caused by part wear in suspension system.

Make sure that the trouble is in the suspension system, not in the steering system, wheel bearings, tires, or other related parts. Suspension system wear can upset steering system operation and change wheel alignment angles. Worn ball joints may let the steering

Copyright Goodheart-Willcox Co., Inc.

knuckles tilt sideways on their control arms. This, in turn, allows the wheels and tires to cock, or lean.

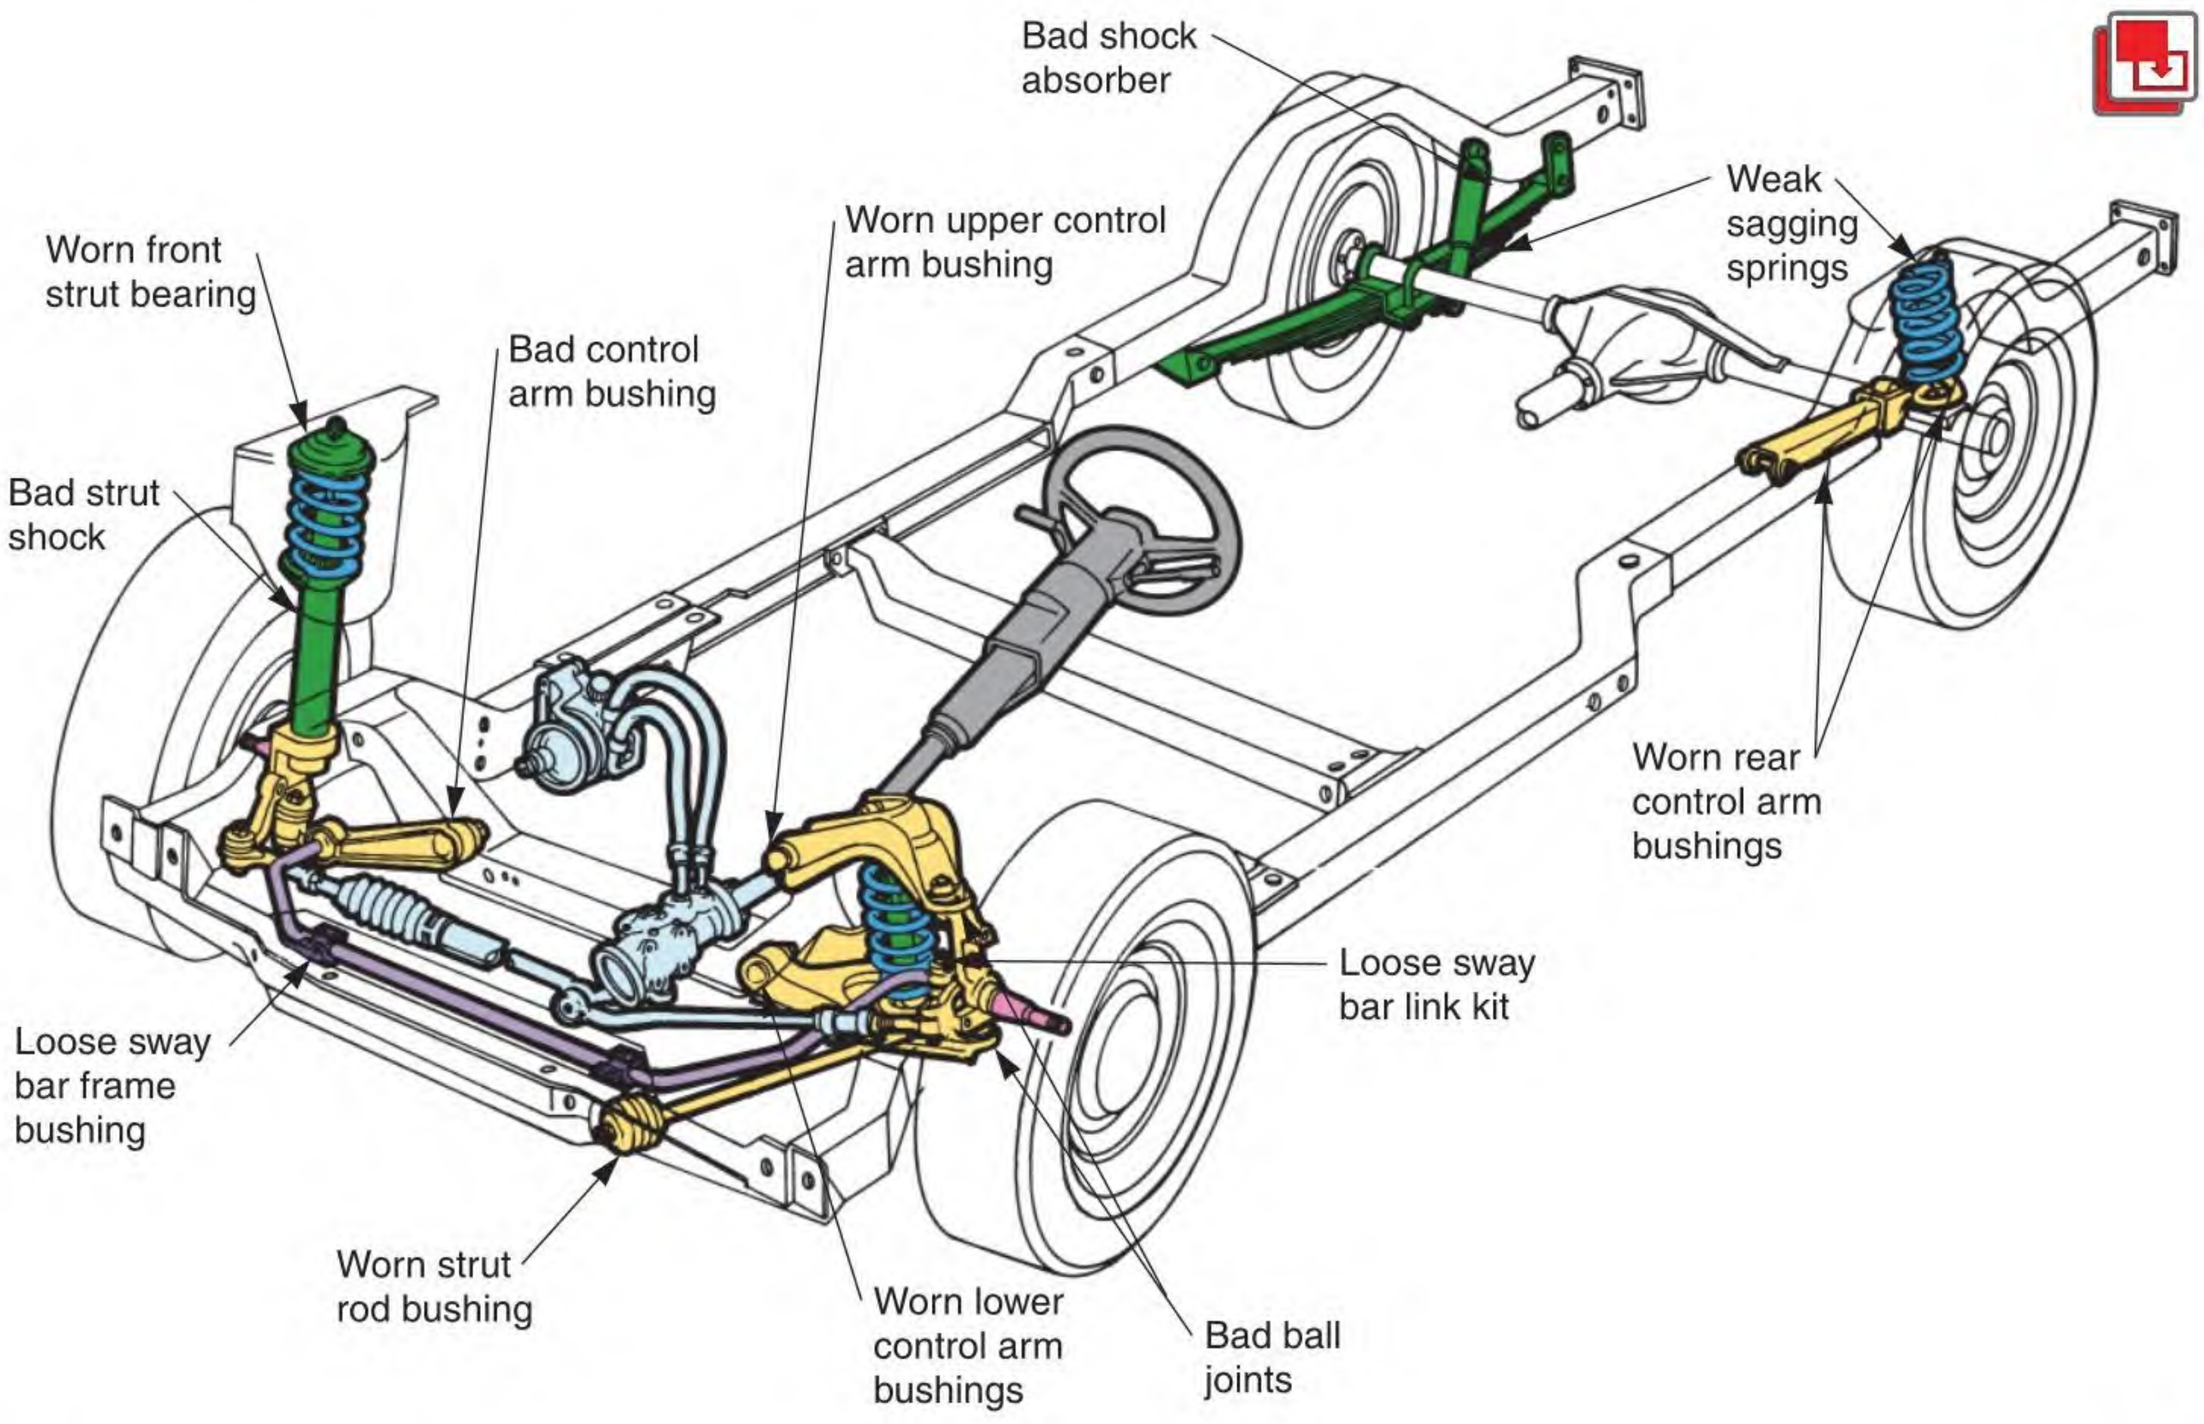
To begin diagnosis of a suspension system, talk to the customer or the service writer. Then, inspect the parts that could cause the problem or test-drive the vehicle.

Figure 76-1 shows typical problem areas. **Figure 76-2** is an exploded view of the parts of a common front-wheel suspension assembly. Study the relationship between parts.

Shock Absorber Service

Worn shock absorbers will cause a vehicle to ride poorly on rough roads. When the tire strikes a bump, a bad shock will not dampen spring oscillations. The suspension system will continue to jounce and rebound up and down. This movement is transferred to the frame, body, and passenger compartment.

A loose or damaged shock absorber may produce a loud clanking or banging sound. The rapid up-and-down suspension movement can hammer the loose shock absorber shaft against the body, shock tower, or control arm.



Checking Shock Absorber Condition

A ***shock absorber bounce test*** and visual inspection will normally locate shock absorber problems. To perform a shock absorber bounce test, simply push down on one corner of the vehicle's body. Then, release the body and count the number of times the vehicle rebounds (moves up and down).

Generally, good shock absorbers should stop body movement in one or two rebounds. Bad shock absorbers will let the body bounce three or more times. The bounce test should be performed on each corner of the vehicle.

Also, inspect the shock absorbers for signs of leakage (oily wetness) and damage. If the shock is leaking oil, new shocks are needed.

Check the rubber bushings on each end of the shock. They should not be smashed or split. Make sure the shock absorber fasteners are tight.

Moog

Figure 76-1. Study the types of problems that can develop in a suspension system.

Copyright Goodheart-Willcox Co., Inc.

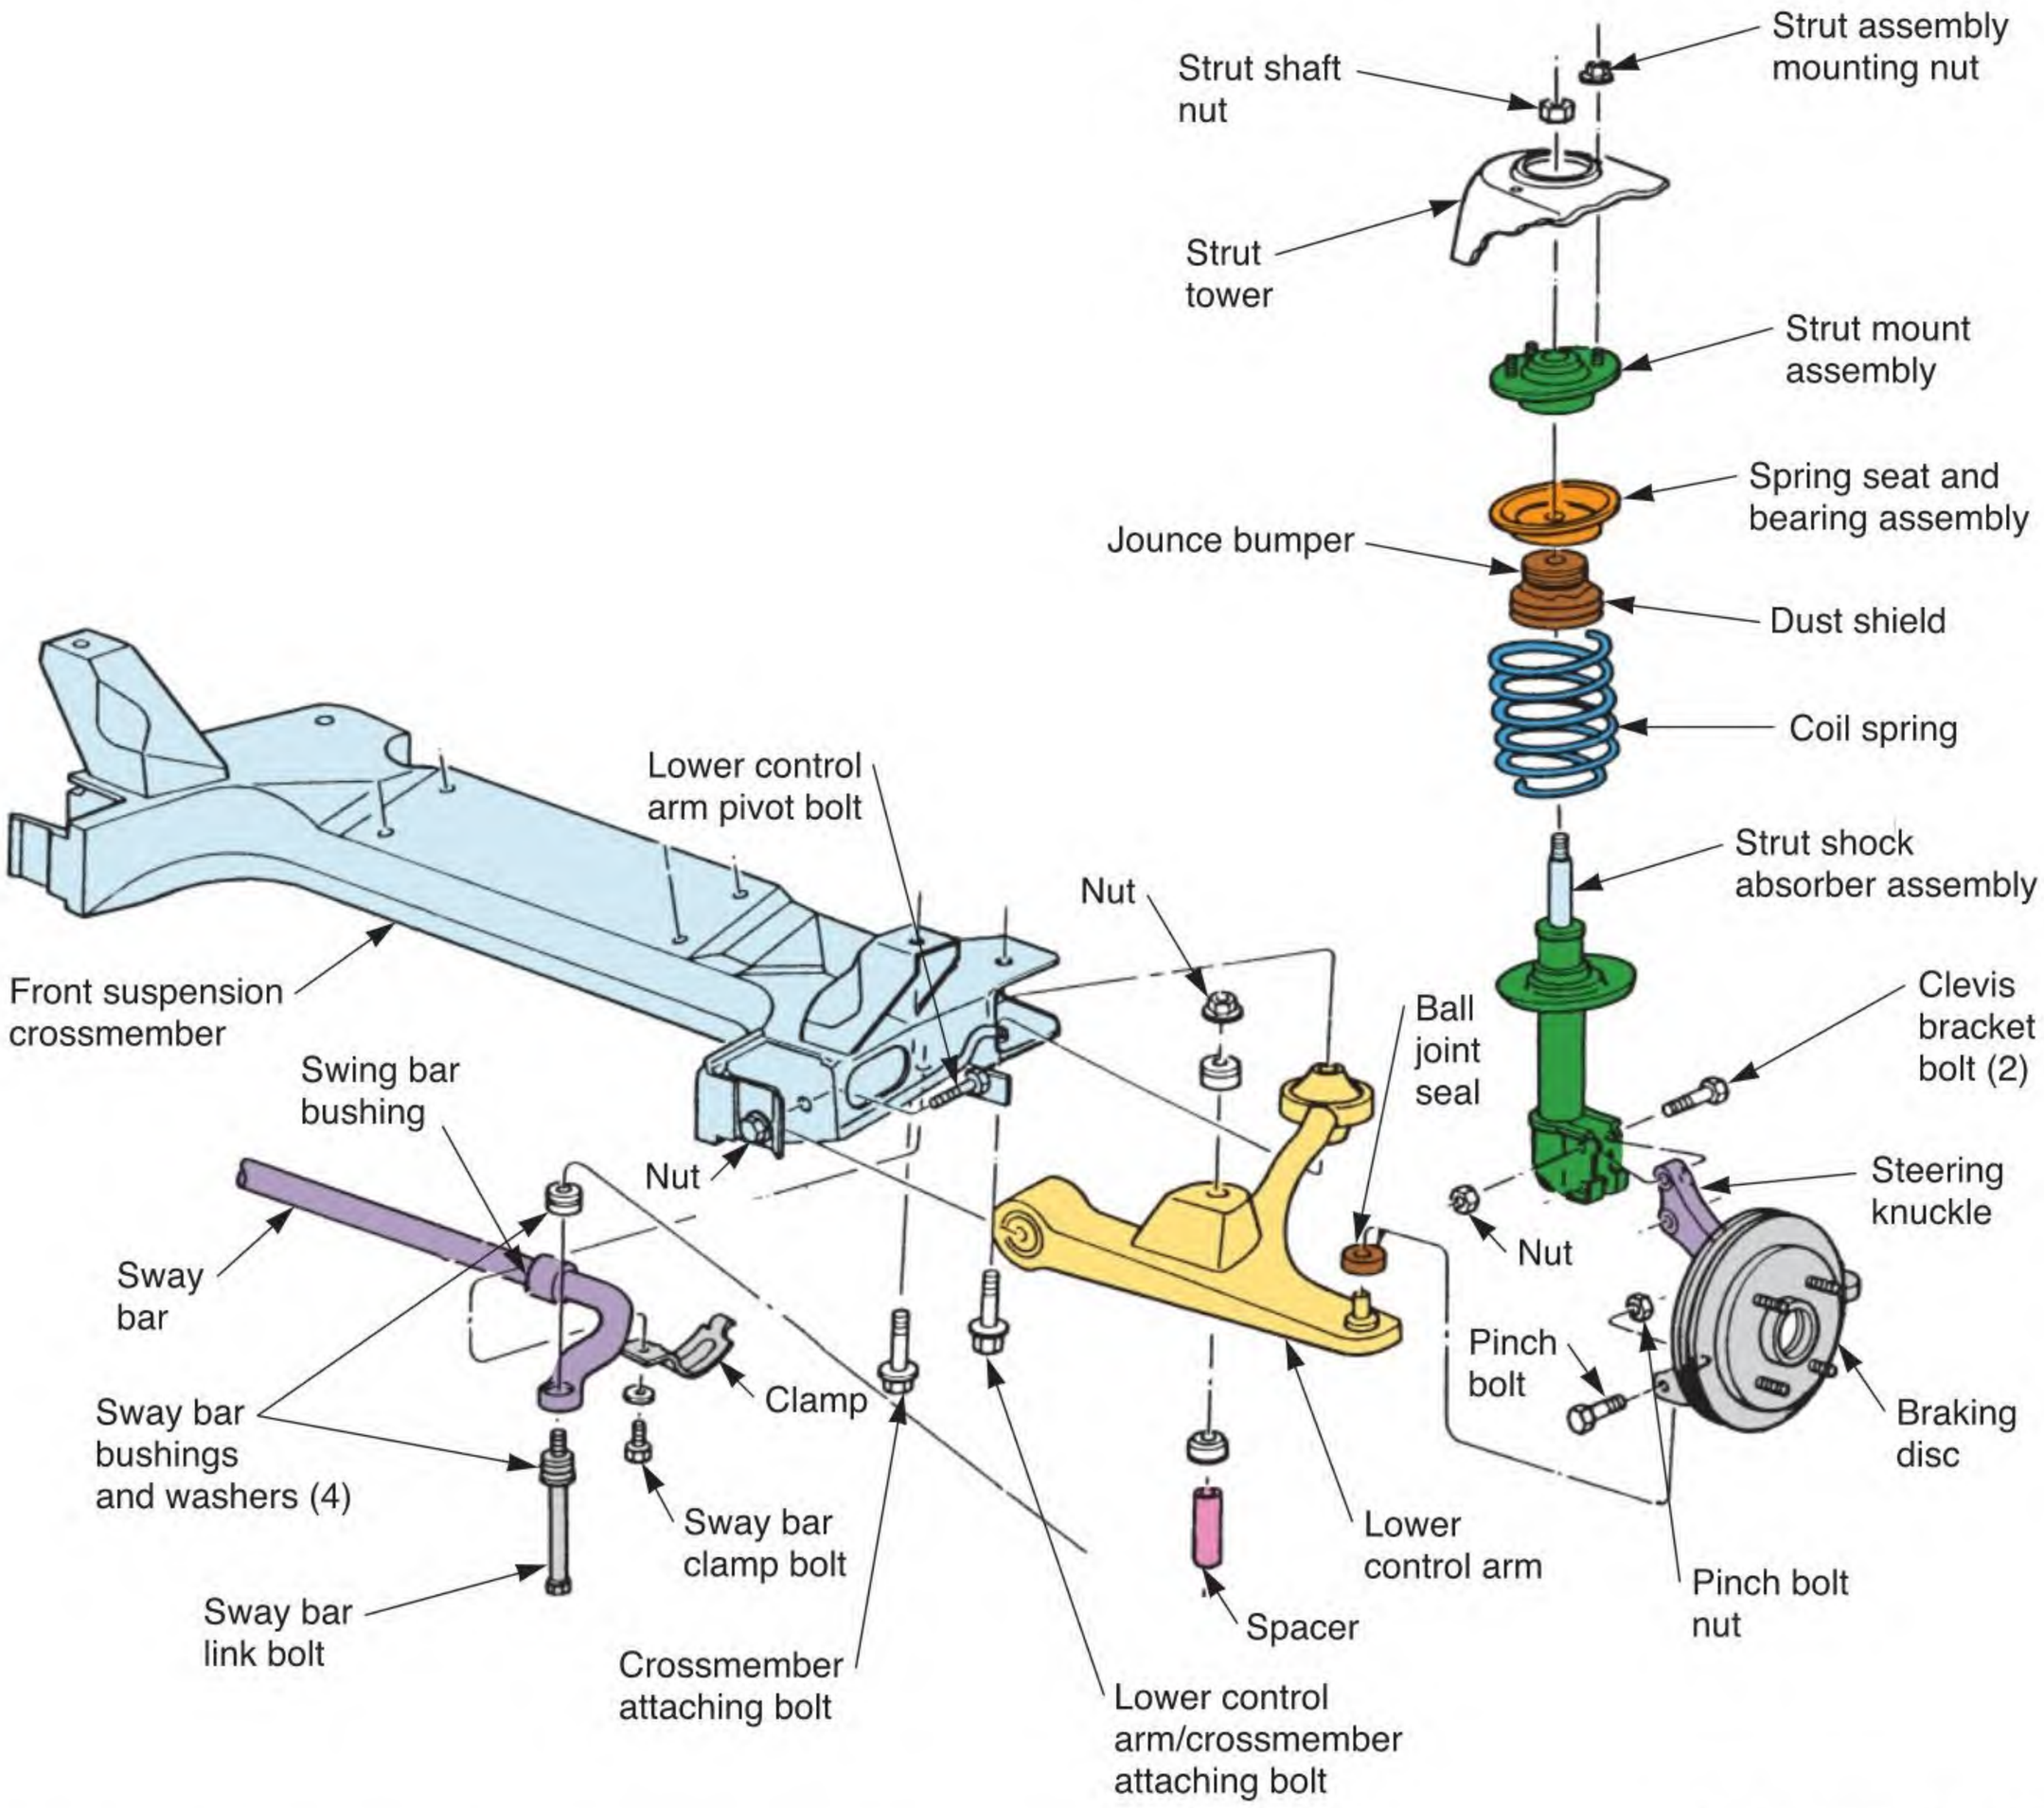


Figure 76-2. Note the parts of this front suspension system.

Replacing Shock Absorbers

When shock absorbers are faulty, they must be replaced.

Warning

With many suspension systems, you must place jack stands or lifting devices under the control arms or the axle before removing the shock absorbers. This will keep the control arms or axle from flying downward when the shocks are unbolted.

Service Procedure

The typical procedure for replacing shock absorbers is as follows:

1. Place the vehicle on jack stands or on a lift.
2. Remove the wheel-and-tire assemblies.
3. Place jack stands or other lifting devices under the control arms or the axle housing, if necessary. See **Figure 76-3A**. Raise the control arm or axle just enough so the shock rod is not

Copyright Goodheart-Willcox Co., Inc.

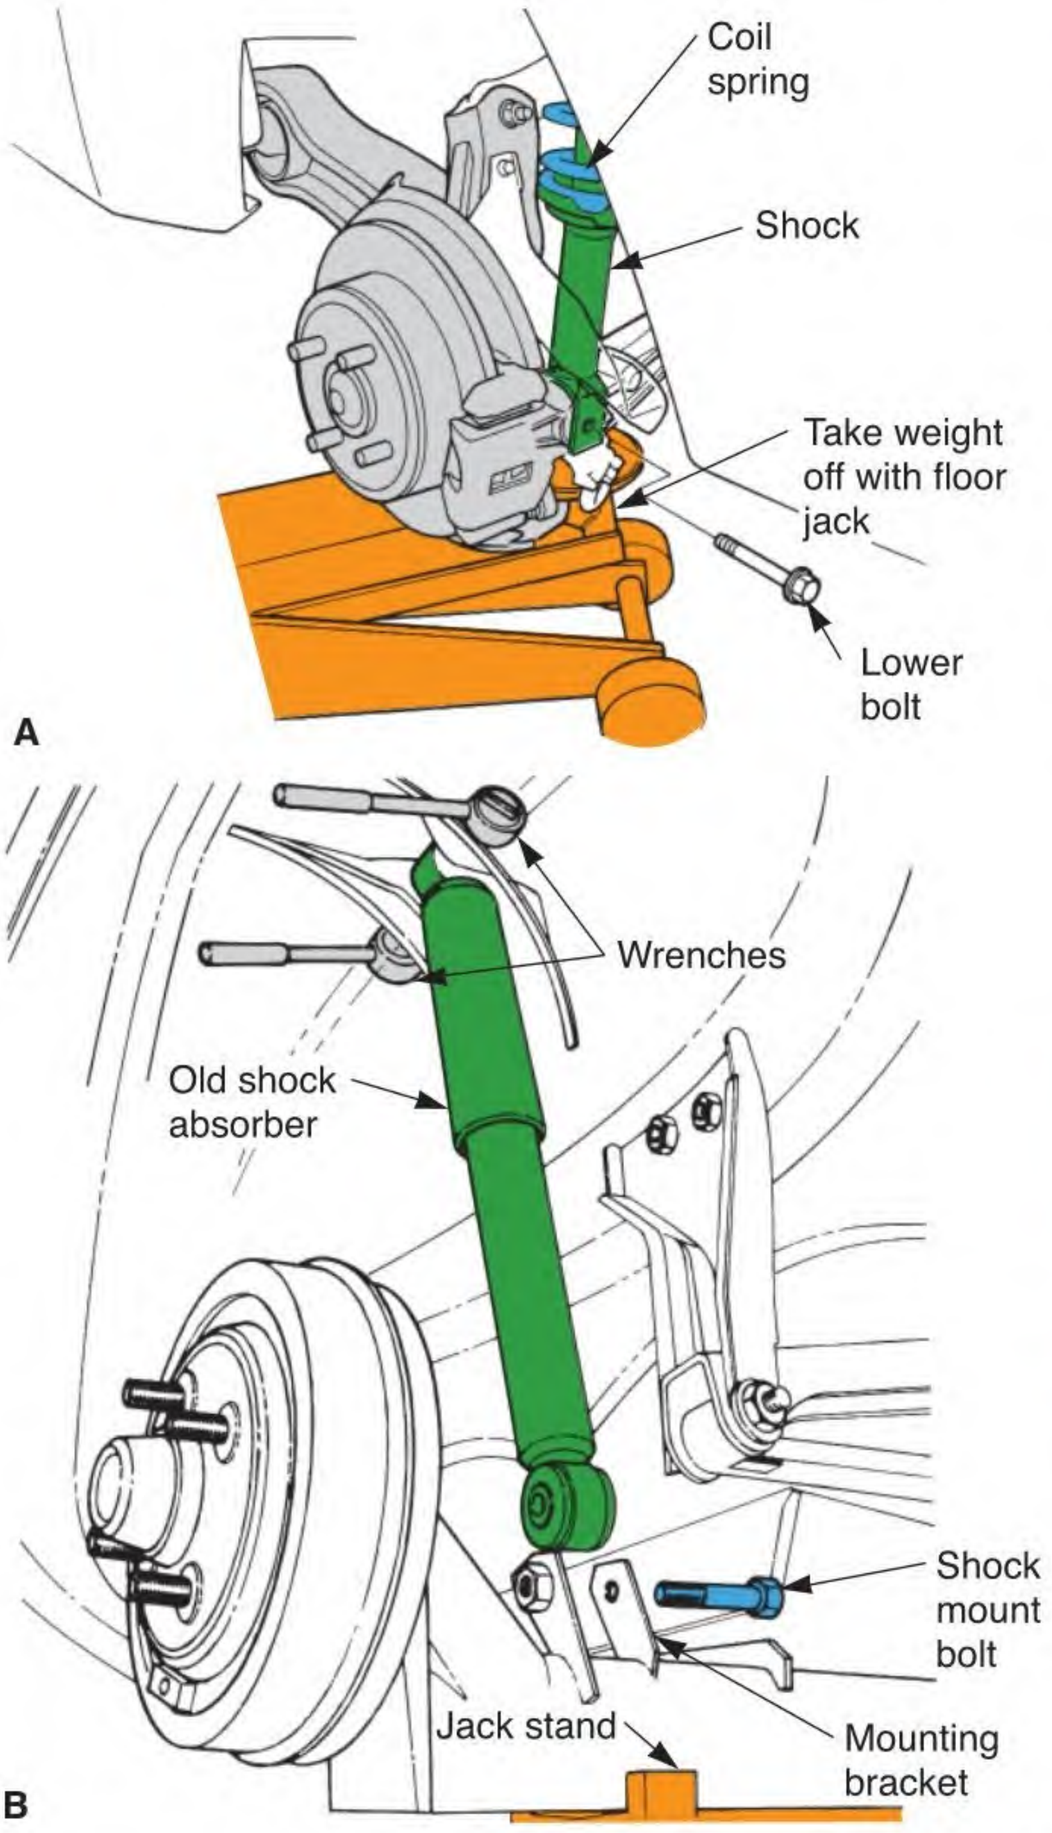

Figure 76-3. A—Before removing the bolts that secure the shock absorber, support the weight of the suspension system to keep the spring from forcing parts down violently. B—Conventional shock absorber removal simply involves unbolting the top and bottom of the shock.

fully extended. You do not want the weight of the axle or fully extended control arm to pull down on the shock rod during removal.

4. Using an air impact gun, remove the fasteners securing the old shock absorbers, **Figure 76-3B**. When a threaded stud and a nut are used, you may need to hold the stud while turning the nut.
5. If the fasteners are rusted, spray rust penetrant on the threads to ease removal of the nuts and bolts.
6. Install the new shock in reverse order of removal.

Air- and Gas-Charged Shock Service

Air- and gas-charged shocks are replaced using the same general procedures described for conventional shocks. Gas-filled shocks must be replaced when faulty. Air shocks may be repairable.

The most common problem with air shocks is air leakage. The air lines, air valve, or shocks can develop pinhole leaks that allow air pressure to bleed off.

To find air leaks, wipe on a soap-and-water solution at possible leakage points, such as air line fittings, shock boots, and air valves. Bubbles are signs of leakage. If a line, fitting, or shock leaks, it should be tightened or replaced.

Caution

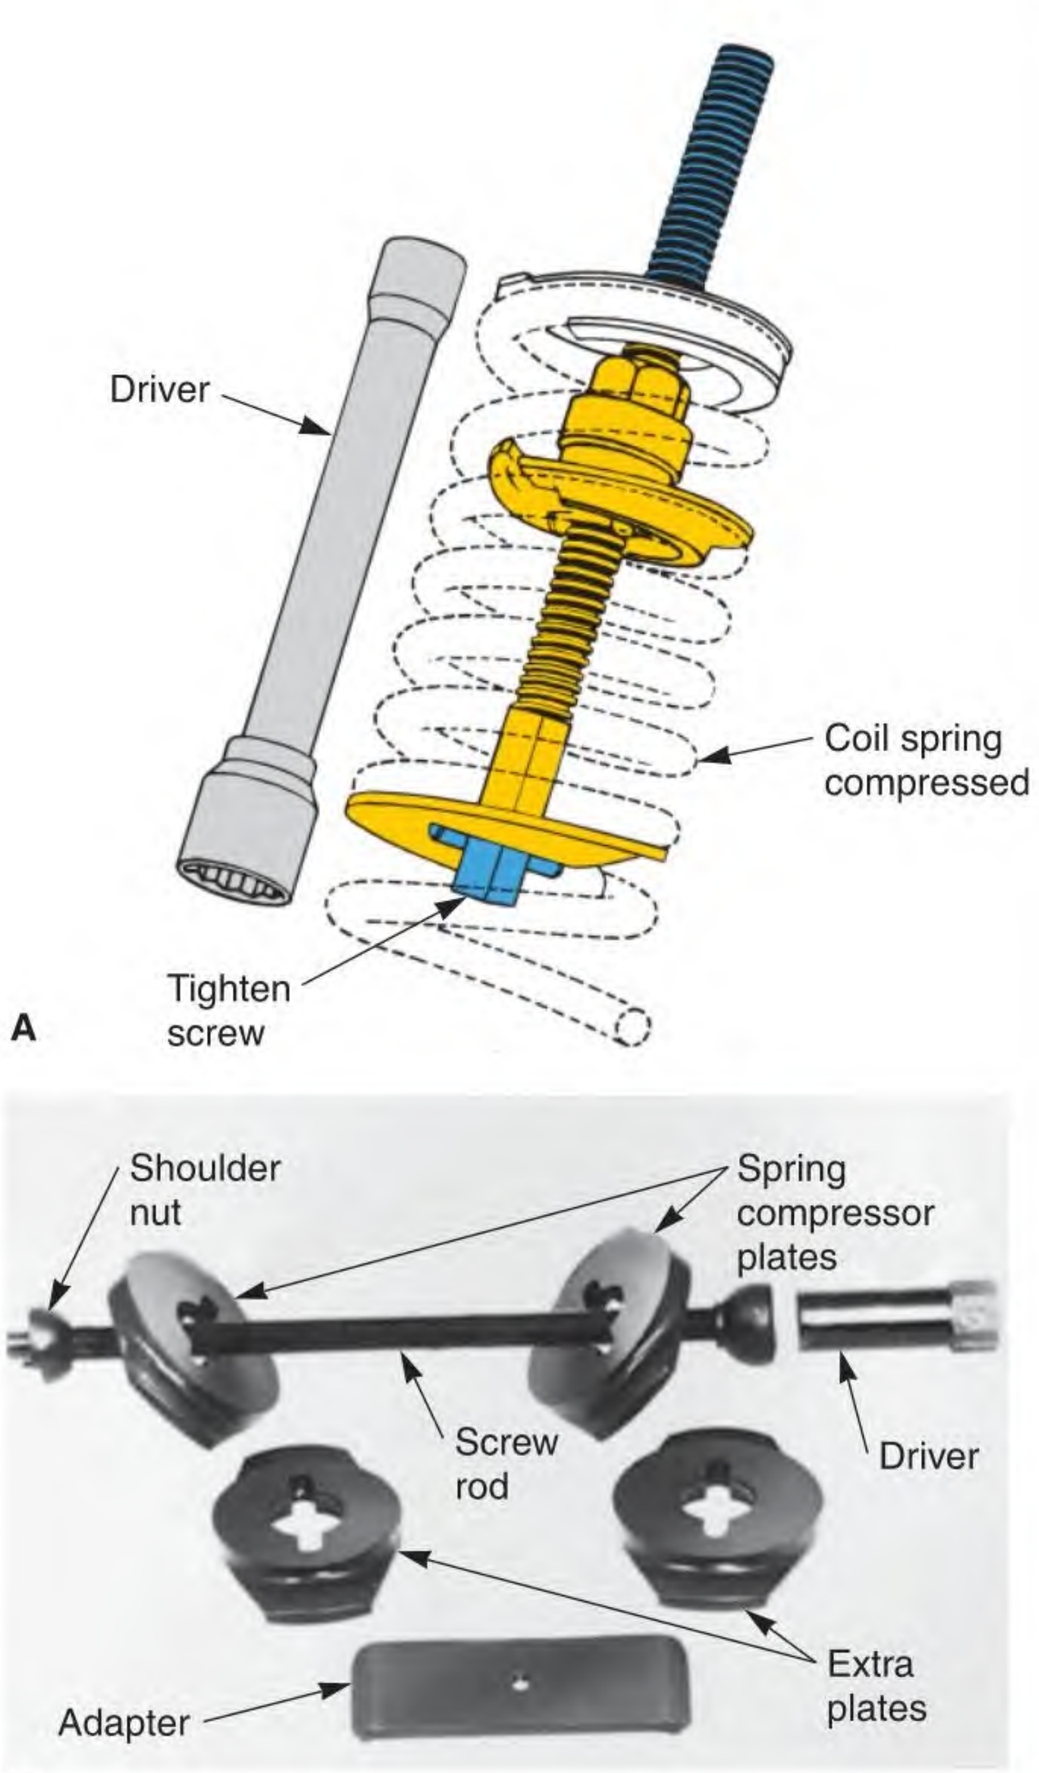
Never exceed the recommended maximum air pressure given for air shocks. If excess pressure is forced into the system, the shocks can be ruptured (blown apart) and ruined.

Suspension Spring Service

Spring fatigue (weakening) allows a vehicle's body to settle toward the axles, lowering vehicle ride height. This settling or sagging changes the position of the control arms, resulting in misaligned wheels. This condition also affects the ride and appearance of the vehicle. Fatigue can occur after prolonged service.

Curb Height and Curb Weight

To check spring condition, measure the vehicle's curb height when the vehicle is at a specified curb weight. ***Curb height*** is the distance from a specific point on the vehicle to the ground. ***Curb weight*** is generally the weight of the vehicle with a full tank of fuel and no passengers or luggage. It is given in pounds or kilograms.



The vehicle should be at curb weight when measuring curb height to determine spring condition. Remove everything from the trunk except the spare tire and jack. Also make sure nothing is in the back or front seats that could increase curb weight.

To measure curb height, place the vehicle on a level surface. Then, measure from a specified point on the frame, body, or suspension down to the shop floor. Compare your measurements to specifications. If the curb height is too low (measurement is too small), replace the fatigued springs.

Copyright Goodheart-Willcox Co., Inc.

Coil Spring Replacement

Fatigued coil springs lower the ride height of the vehicle and throw off the suspension geometry. A ***coil spring compressor*** is needed to remove and install a coil spring. The screw-type compressor squeezes the spring coils closer together, reducing the overall height of the coil spring. This gives you enough room to slide the spring out of the control arm. See **Figure 76-4**.

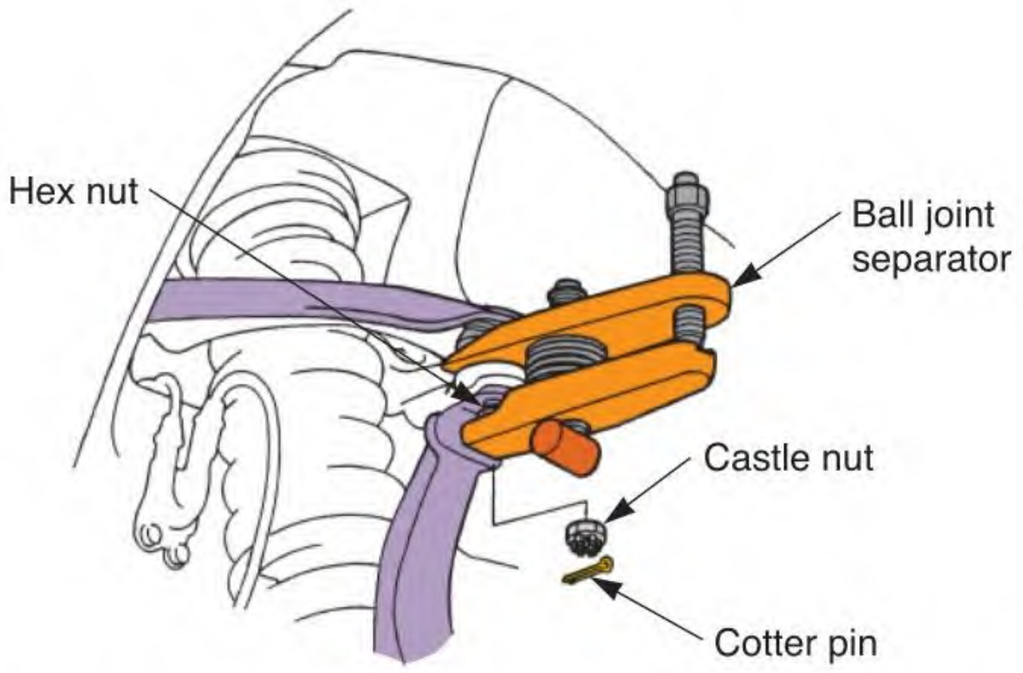
OTC Div. of SPX Corp.

Figure 76-4. A coil spring compressor must be used to squeeze the coils together before unbolting the ball joints. This will keep the spring from flying out with deadly force.

Tech Tip

Many full-size pickup trucks still use a large coil spring mounted against the control arm. They do not use a McPherson strut suspension because it cannot support such a heavy load.

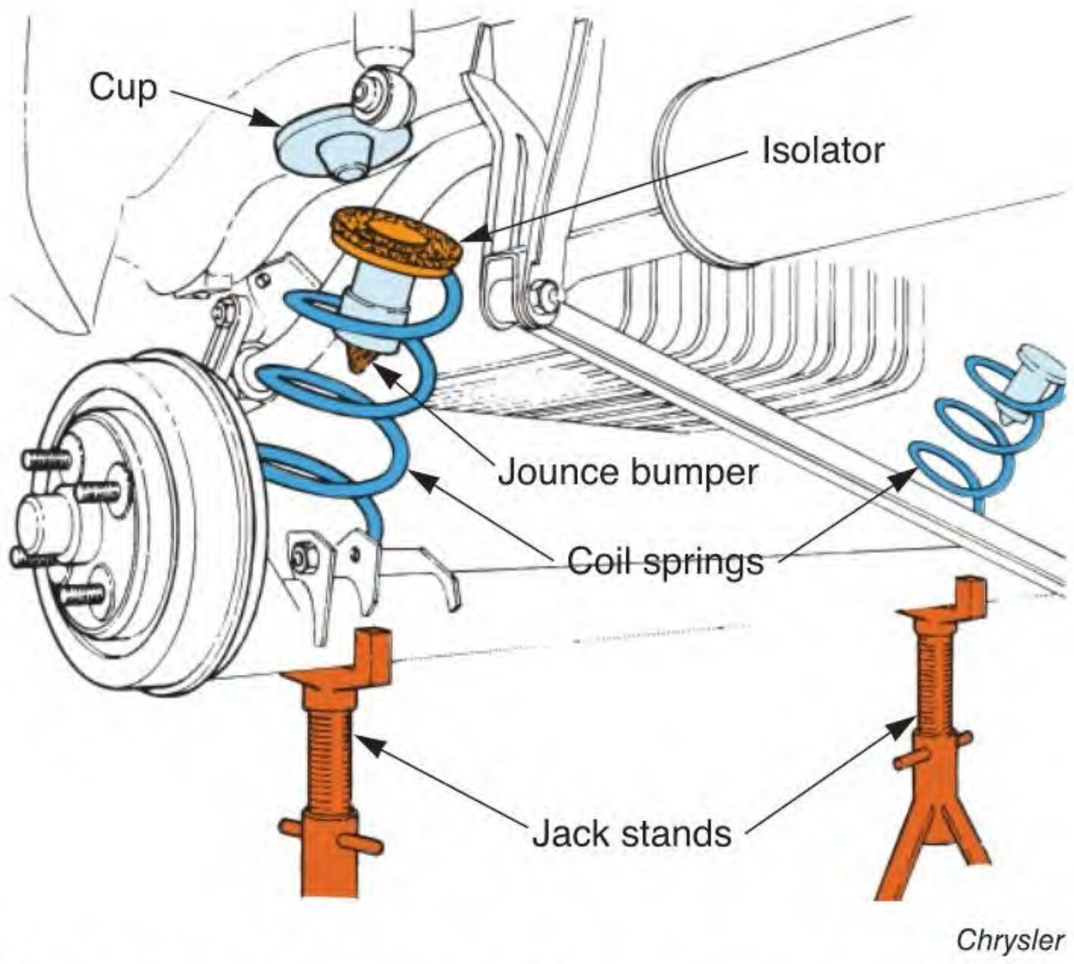
Service Procedure



To remove a coil spring:

1. Place the vehicle on jack stands and remove the shock absorber.
2. Install the spring compressor over the coil spring. Follow tool directions.
3. Oil the tool threads to ease spring removal. Then tighten the tool down to compress and shorten the spring.
4. Depending on the suspension system design, you may have to separate the lower or upper ball joint. Refer to the service manual for details.
5. Use a ***fork tool***, or ***ball joint separator***, and hammer blows to remove the ball joint from the steering knuckle. Special pullers and drivers are also available for ball joint separation, **Figure 76-5**.
6. Remove any other components (brake line, strut rod, steering linkage) that could be damaged when the control arm is lowered.
7. Pull the spring and the compressor out as a unit.

Warning



A compressed coil spring has a tremendous amount of stored energy. *Never* unbolt the ball joint without *first* compressing the coil spring. If the spring is *not* compressed, the lower control arm and the spring could shoot downward with *deadly force* as soon as the ball joint is unbolted. The suspension arm can fly down with enough force to break your legs!

Copyright Goodheart-Willcox Co., Inc.

Honda

Figure 76-5. A fork or ball joint separator is used to force the ball joint stud out of the steering knuckle.

Chrysler

Figure 76-6. A rear coil spring can usually be removed by simply dropping the axle slowly after unbolting the shock.

Service Procedure

To install a new coil spring:

1. Compress the new spring with the spring compressor.
2. Slip the spring into place and position the coil ends in the same location as the ends of the old spring.
3. Reassemble the ball joint and other components.
4. Unscrew the spring compressor while guiding the coil into its seats.

Warning

Keep your fingers out from under or near a compressed suspension system spring. They could be badly crushed or severed if the tool slips off and releases the spring's stored kinetic energy.

When replacing a rear coil spring, a spring compressor may *not* be needed. After shock removal, the axle should drop far enough to free the coil spring. Support the weight of the axle or hub on jack stands or a floor jack, **Figure 76-6**. Always reinstall isolators or the new spring could squeak or rattle. Check a service manual for exact procedures.

Leaf Spring Service

Leaf spring service usually involves spring or bushing replacement. Leaf springs can break, especially in the middle. Always inspect leaf springs closely for cracks. Look at both edges of each spring near the axle mount.

Tech Tip

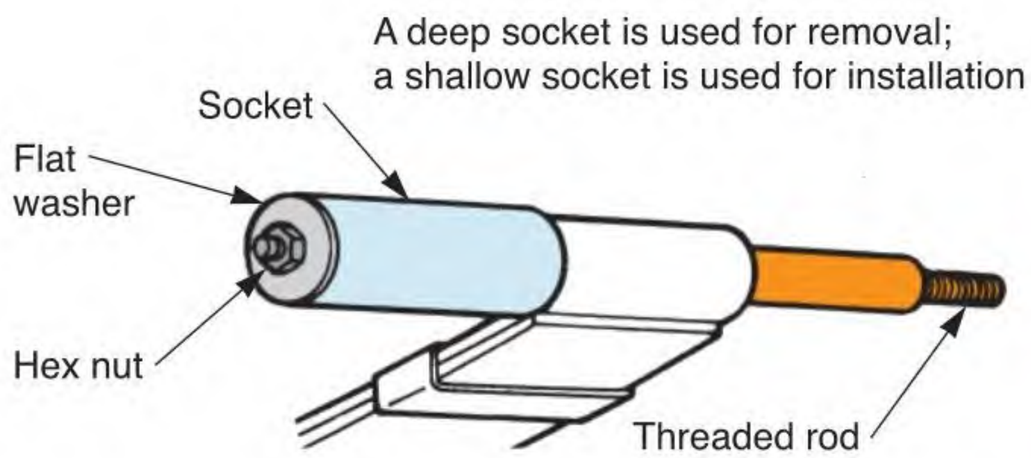
Leaf springs are still used on the new Chevrolet Corvette. A transverse leaf spring supports the rear suspension control arms. Some large trucks also use leaf springs at the rear. Modern leaf springs can be made of spring steel or carbon fiber.

Service Procedure

To replace a leaf spring:

1. Place jack stands under the frame and use a floor jack to raise the weight of the rear axle off the leaf spring.
2. Use a box wrench and an impact wrench to remove the nuts on each end of the leaf spring. Leave the through-bolts installed.

Copyright Goodheart-Willcox Co., Inc.



3. Remove the U-bolts that clamp around the middle of the spring and the axle. If the jack is adjusted properly, the through-bolts should now slide out with little resistance.
4. Lift the old leaf spring off the vehicle.

Warning

Never drive out the leaf spring eye bolts or shackle bolts unless all force is released from the spring. The eye or shackle bolts should pull out or drive out easily. If the bolts are removed with weight on the spring, the spring could fly upward or downward with *lethal force*.

5. Install the new leaf spring in the opposite order.
6. Make sure you position the axle assembly on the leaf spring correctly. A small guide pin may be provided to ensure proper rear axle alignment. The pin must fit through a hole in the leaf spring.

When just the leaf spring bushings are worn, they can be replaced without spring removal. With the through-bolt removed, select the correct diameter pulling-driving tool, **Figure 76-7**. One end of the tool should fit inside the spring eye, and the other end should contact the face of the eye. Tighten the tool nut to force out the old bushing. To install the new spring bushing, use the tool to pull the bushing into the spring eye. Install the spring eye bolts and torque them to specifications.

Chrysler

Figure 76-7. A driving tool makes worn bushing removal easy. When the hex nut is tightened, the tool pushes the bushing out of the spring.

Torsion Bar Service

Most torsion bars are adjustable. Therefore, torsion bar replacement is *not* frequently needed. A torsion bar and its related components are illustrated in **Figure 76-8**.

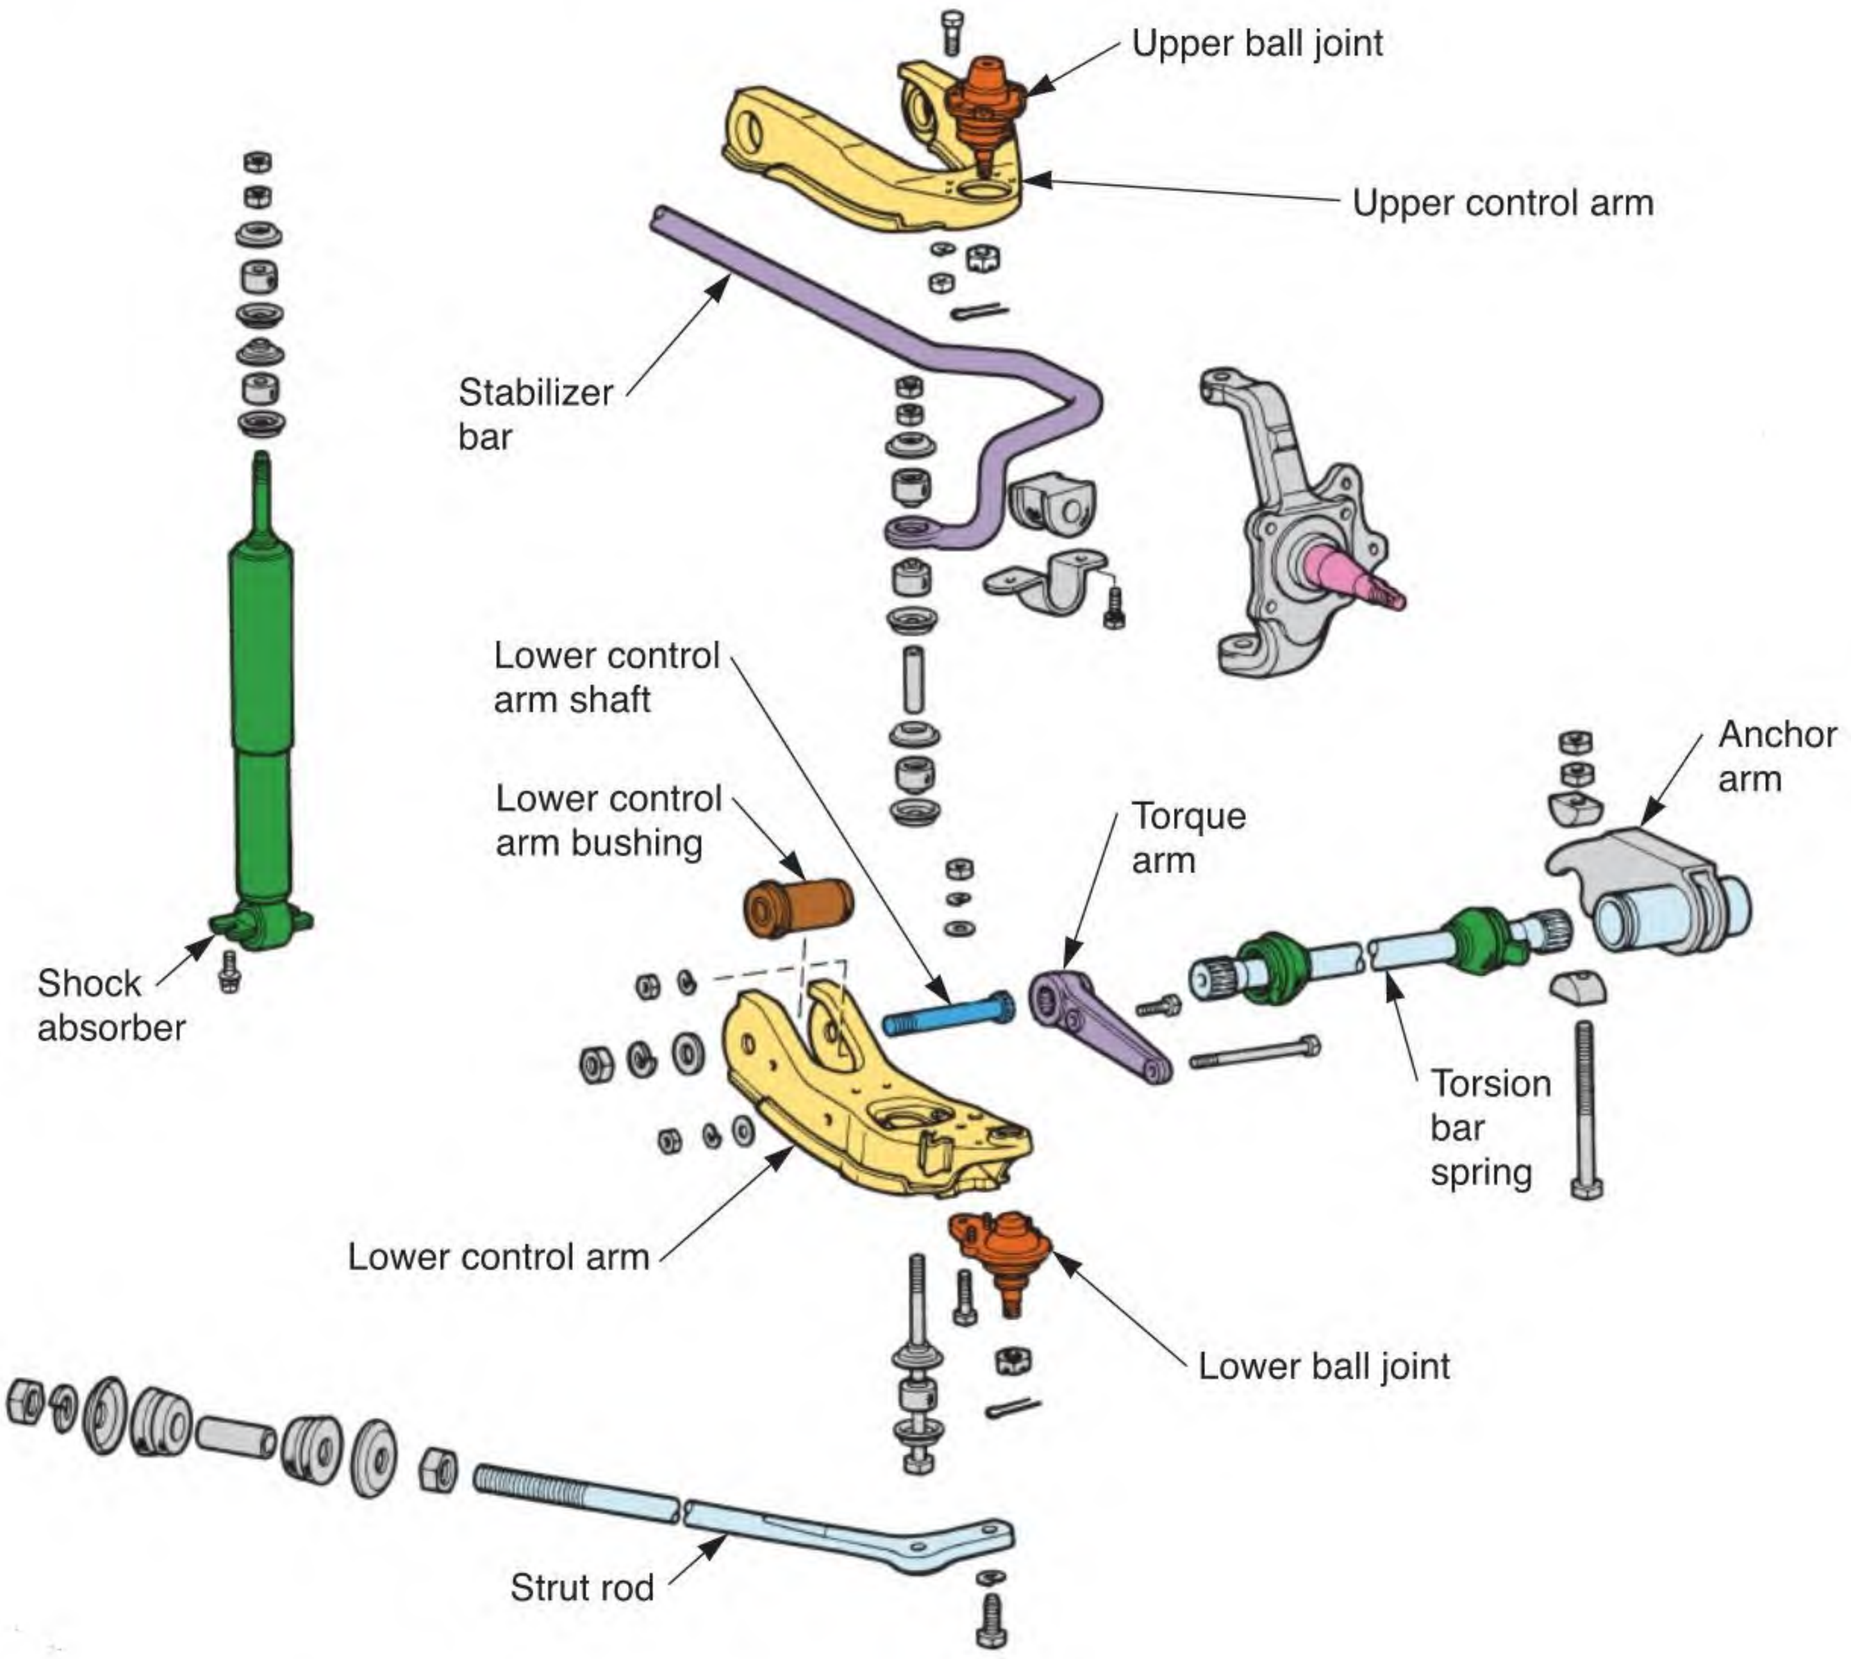
To adjust a torsion bar, you must usually turn a bolt to increase or decrease the tension, or twist, on the bar. When curb height is too low, tension must be increased to raise the vehicle.

Ball Joint Service

Worn ball joints cause the steering knuckle and wheel assembly to be loose on the control arms. A worn ball joint might make a clunking or popping sound when turning or when driving over a bump.

Ball Joint Lubrication

Ball joint wear is usually a result of improper lubrication or prolonged use. The load-carrying ball joints support the weight of the vehicle while swiveling into various angles. If not greased, the joints will become dry and can wear out quickly. Look at **Figure 76-9**.



A dry ball joint is easily identified because its rubber boot is collapsed inward—it is not swollen with grease. When you squeeze a properly greased boot with your fingers, you will feel a slight pressure, similar to an air-filled balloon. If dry, the boot will feel hard because the boot is collapsed and is touching the joint ball.

Grease fittings or lube plugs are usually provided for ball joint lubrication. If plugs are provided, they must be replaced with grease fittings before the joint can be lubricated. A ***grease gun*** is used to inject chassis grease into the ball joint grease fittings. This is illustrated in **Figure 76-10A**.

Caution

When greasing a ball joint equipped with a balloon seal (airtight seal), be careful not to inject too much grease. Inject only enough grease to cause the seal to bulge slightly. Too much grease can rupture the rubber boot. See **Figure 76-10B**.

Copyright Goodheart-Willcox Co., Inc.

Toyota

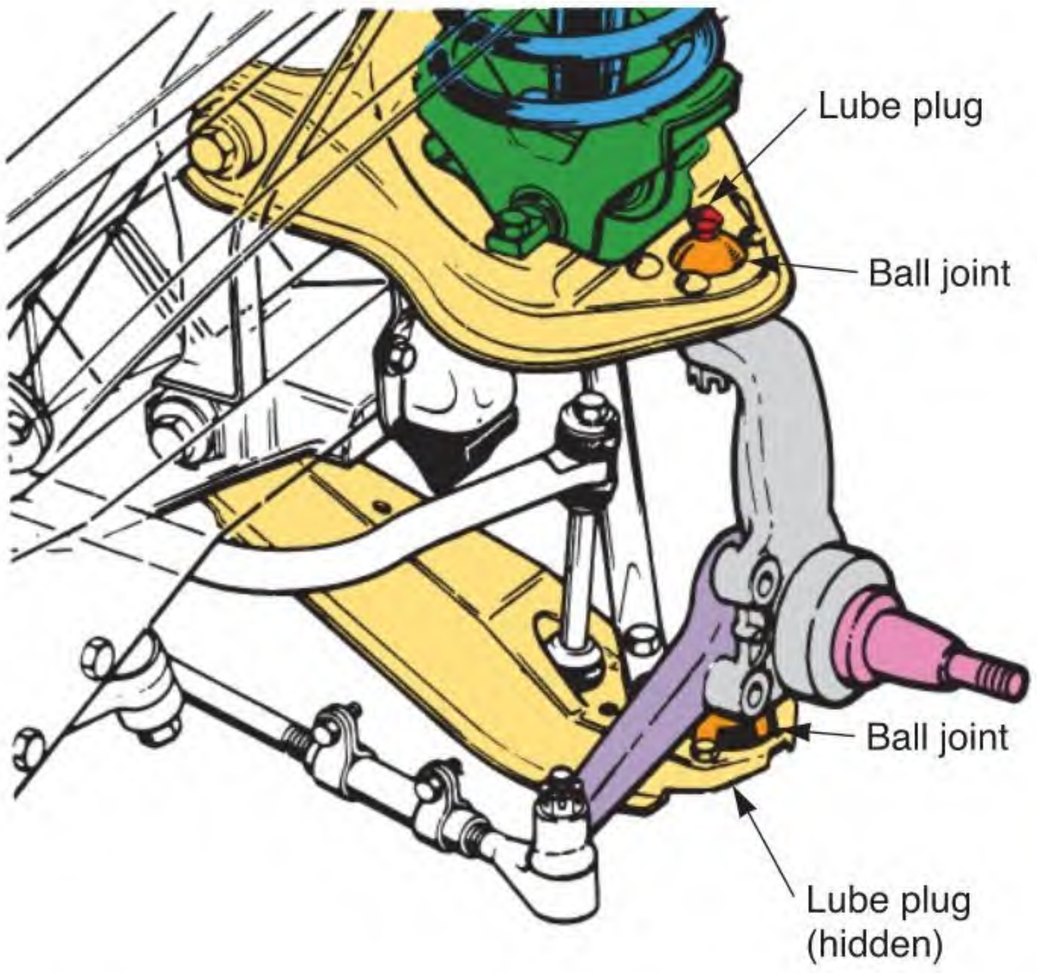
Figure 76-8. Exploded view of a torsion bar suspension. Study the part relationships.

Checking Ball Joint Wear

To check for ball joint wear, inspect the ***ball joint wear indicator*** or measure the play in the joint. With a ball joint wear indicator, simply inspect the shoulder on the joint to determine ball joint's condition. If the shoulder on the joint is recessed, the joint should be replaced. This is shown in **Figure 76-11**.

Another way to check ball joint wear involves jacking up the vehicle and physically moving the control arm and joint. Depending on the type of suspension, you may need to raise the vehicle by the frame or by the lower control arm, **Figure 76-12**. With the suspension properly raised, use a long steel pry bar to wiggle the tire up and down and sideways. While wiggling, note the amount of movement in the ball joints. Refer to service manual specifications and replace any ball joint that is worn too much and shows movement and play. See **Figure 76-13**.

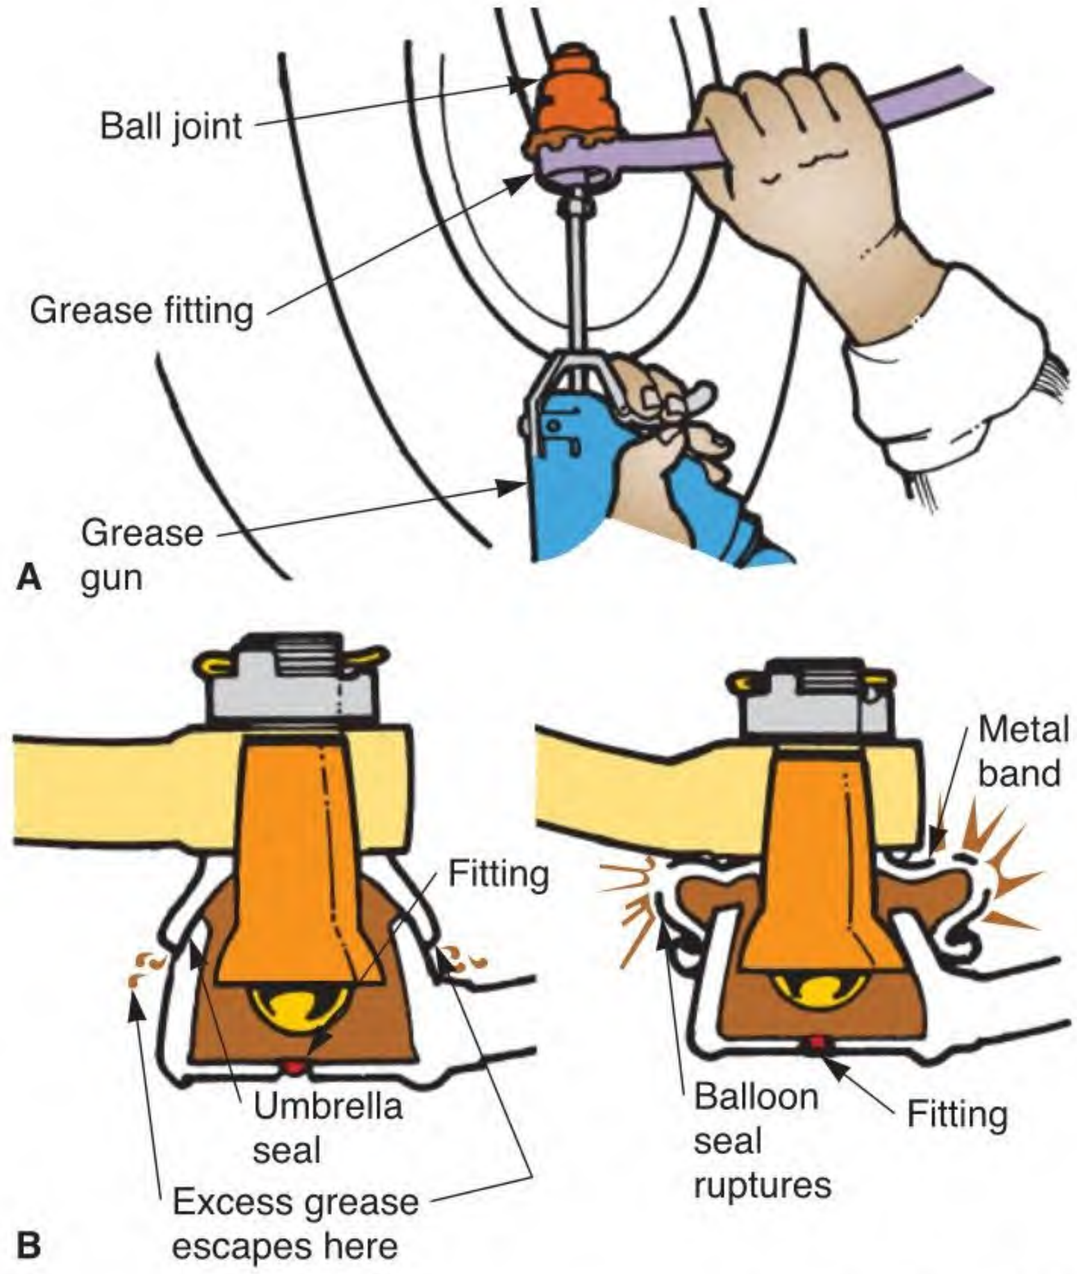
Ball Joint Replacement



A ball joint can usually be replaced without removing the control arm from the vehicle. However, it is sometimes necessary to replace the entire control arm to replace a worn ball joint.

Service Procedure

To replace a ball joint:



1. Place the vehicle on jack stands.
2. Remove the shock absorber and install a spring compressor on the coil spring.
3. Remove the nut securing the ball joint to the steering knuckle and separate the knuckle and

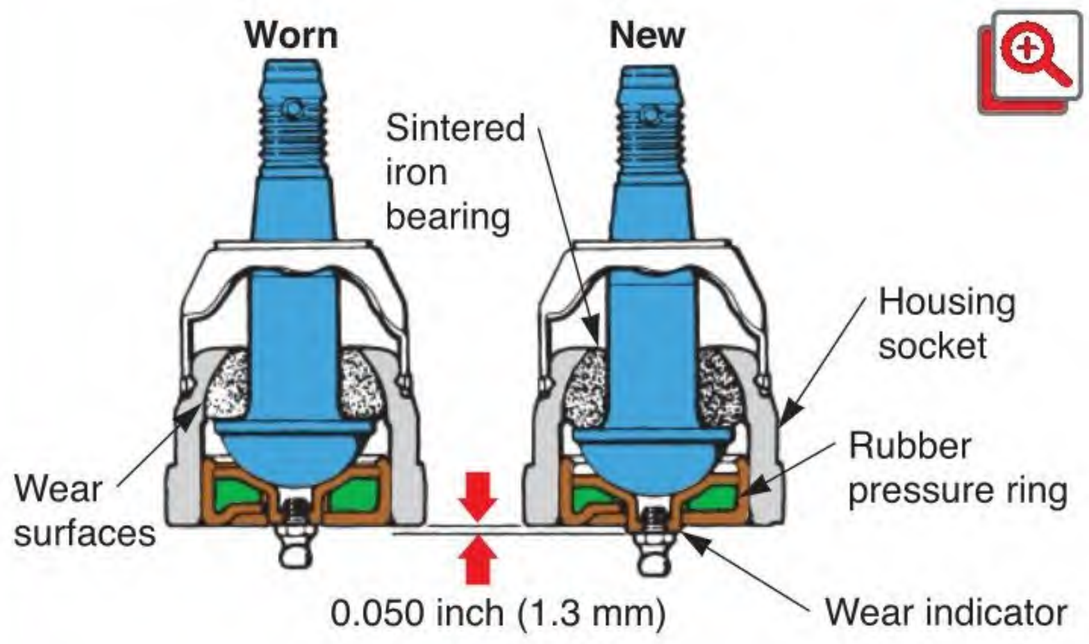
Chrysler

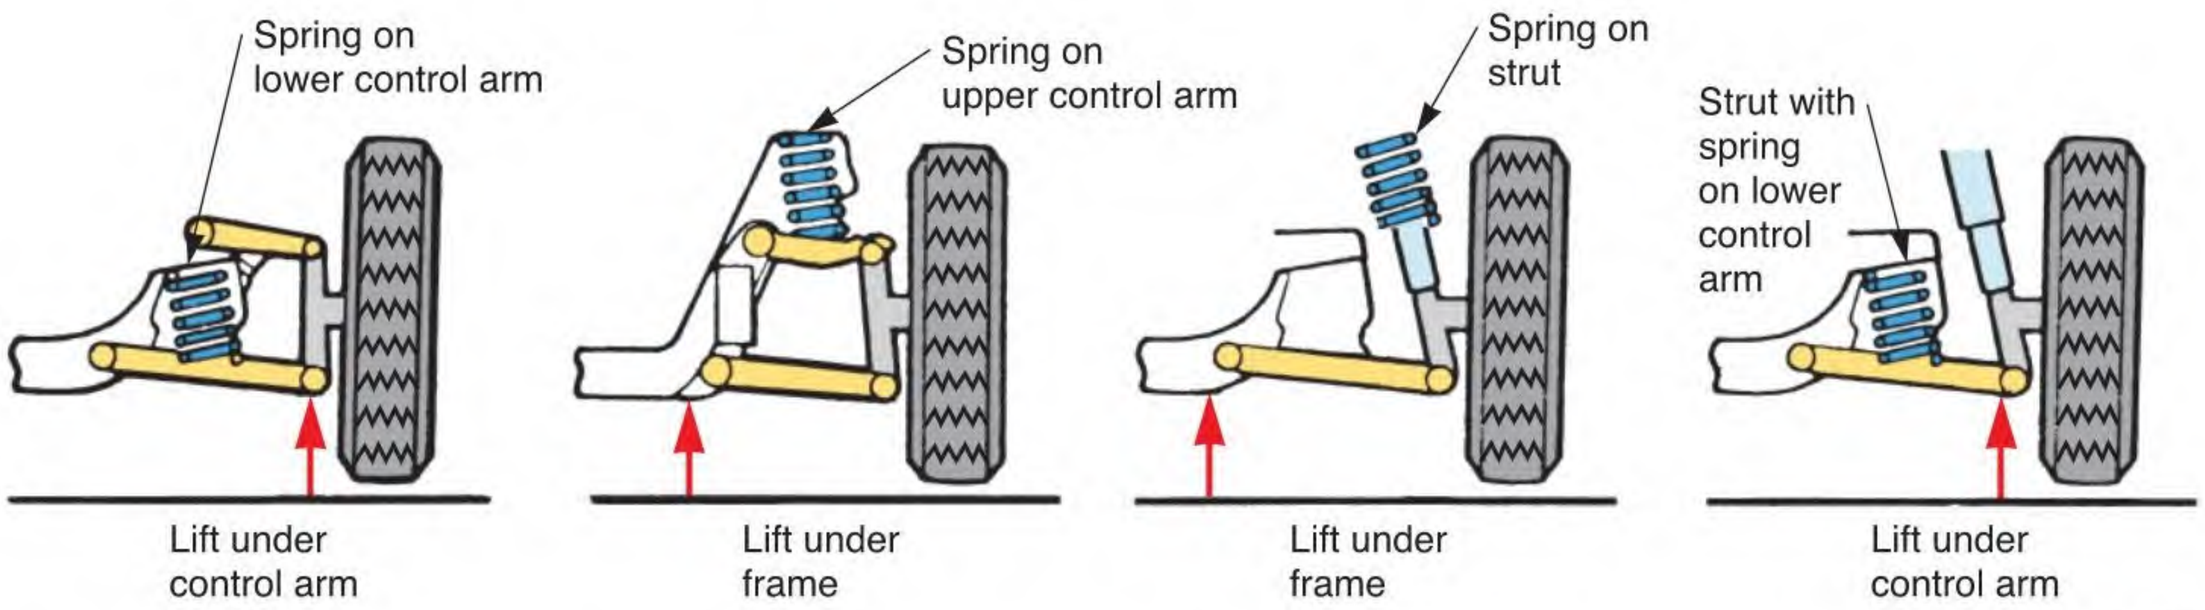
Figure 76-9. Grease fittings or lube plugs are normally provided at the upper and lower ball joints. Grease fittings can also be located on the upper shaft of the inner control arm and on the steering components.



Florida Dept. of Voc. Ed.

Figure 76-10. Dry, unserviced ball joints wear and fail quickly. A—After cleaning the outside of the fitting, use a grease gun to force chassis grease into the ball joints or other fittings. B—Only install enough grease to fill the boot. Too much grease can rupture some types of boots.

the joint. The ball joint may be pressed, riveted, bolted, or screwed into the control arm. A service manual will give the details for the specific make and model vehicle.



4. If the ball joint is pressed in, it can be hammered or driven out with a special tool. Be careful not to damage the control arm.
5. If the ball joint is riveted in place, drill out the old rivets with the correct diameter drill bit.
6. Use hardened bolts (that come with the kit) to secure the new unit. **Figure 76-14** illustrates service of a riveted ball joint.
7. If the ball joint is screwed into place, use a large wrench to unscrew it.
8. If it is rusted, free the threads with rust penetrant or heat from a torch first.
9. Clean the threads in the control arm before threading in the new ball joint.
10. Torque the ball joint properly.

Moog

Figure 76-11. This ball joint has a wear indicator. When the shoulder recedes into the socket, a new joint is needed.

Goodheart-Willcox Publisher

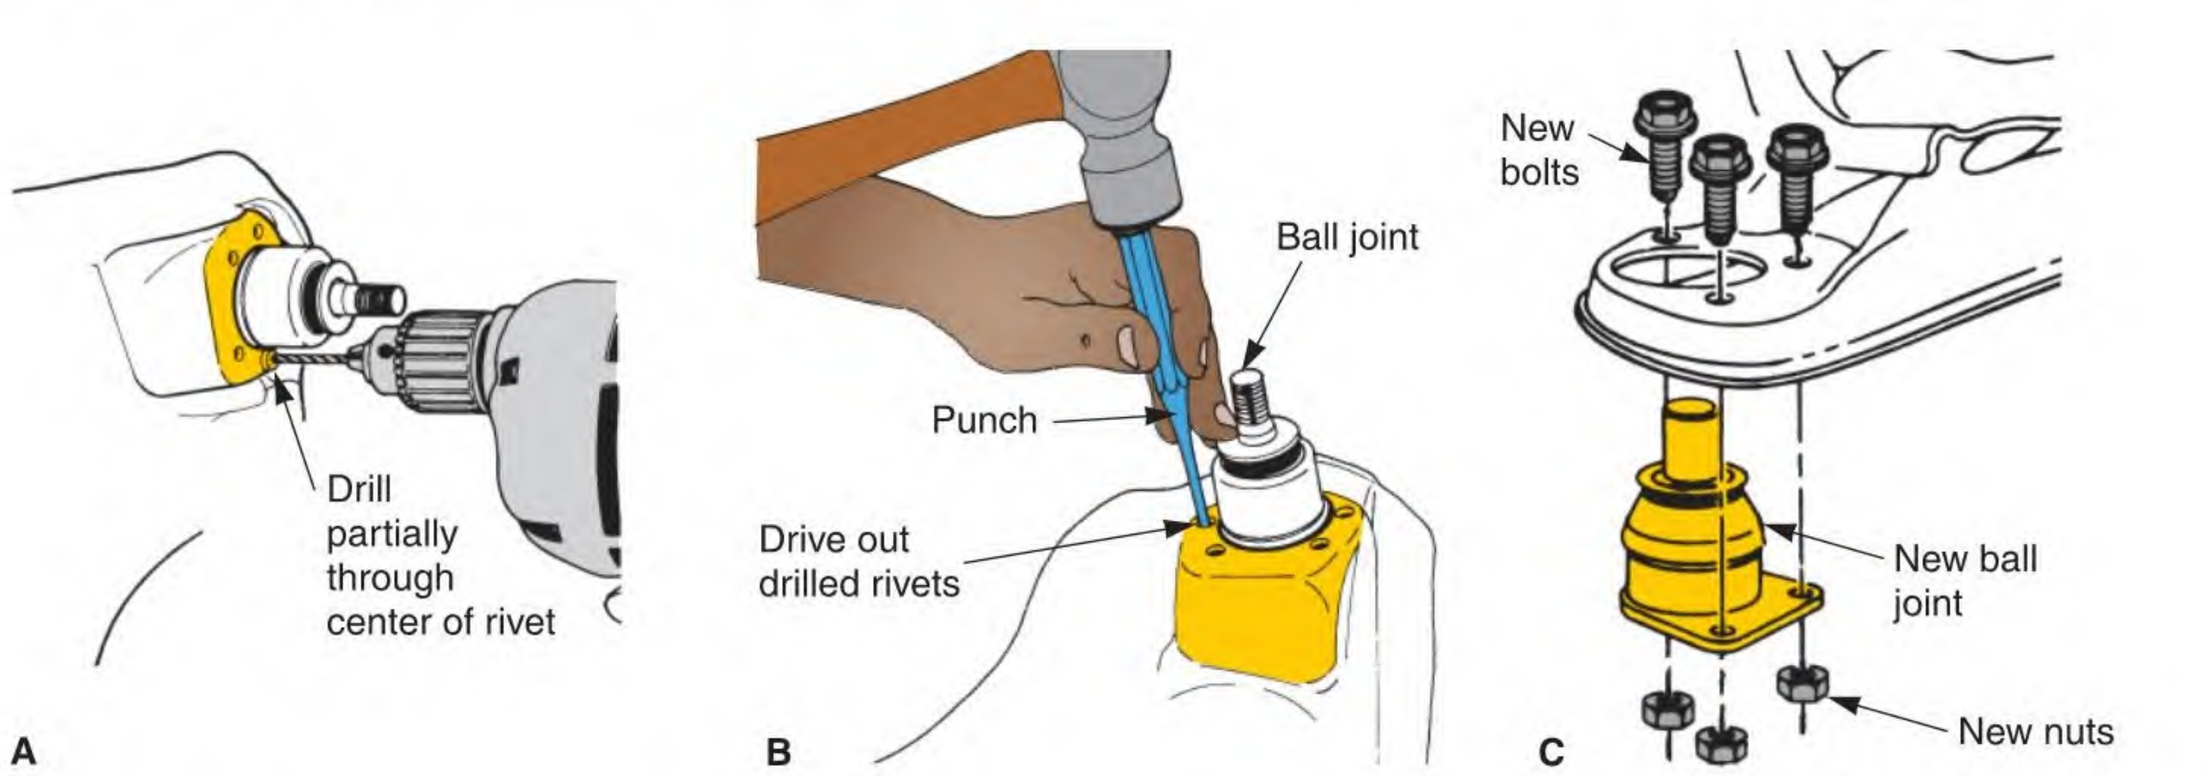

Figure 76-13. With the vehicle jacked up properly, use a long pry bar to wiggle the tire up and down. This will help detect part wear.

Warning

Always install a *new cotter pin* when a ball joint nut is removed. An old cotter pin could break, causing a serious auto accident. The wheel and tire can come off the car, causing the driver to lose control of the vehicle.

Suspension Bushing Service

Rubber bushings are commonly used in the inner ends of front control arms, rear control arms, and other parts. These bushings are wear prone and should be inspected periodically.

Goodheart-Willcox Publisher

Figure 76-14. Replacement of a riveted ball joint. A—Drill out the rivet heads. B—Use a punch to drive out the rivets. C—Bolt on the new ball joint.

Copyright Goodheart-Willcox Co., Inc.

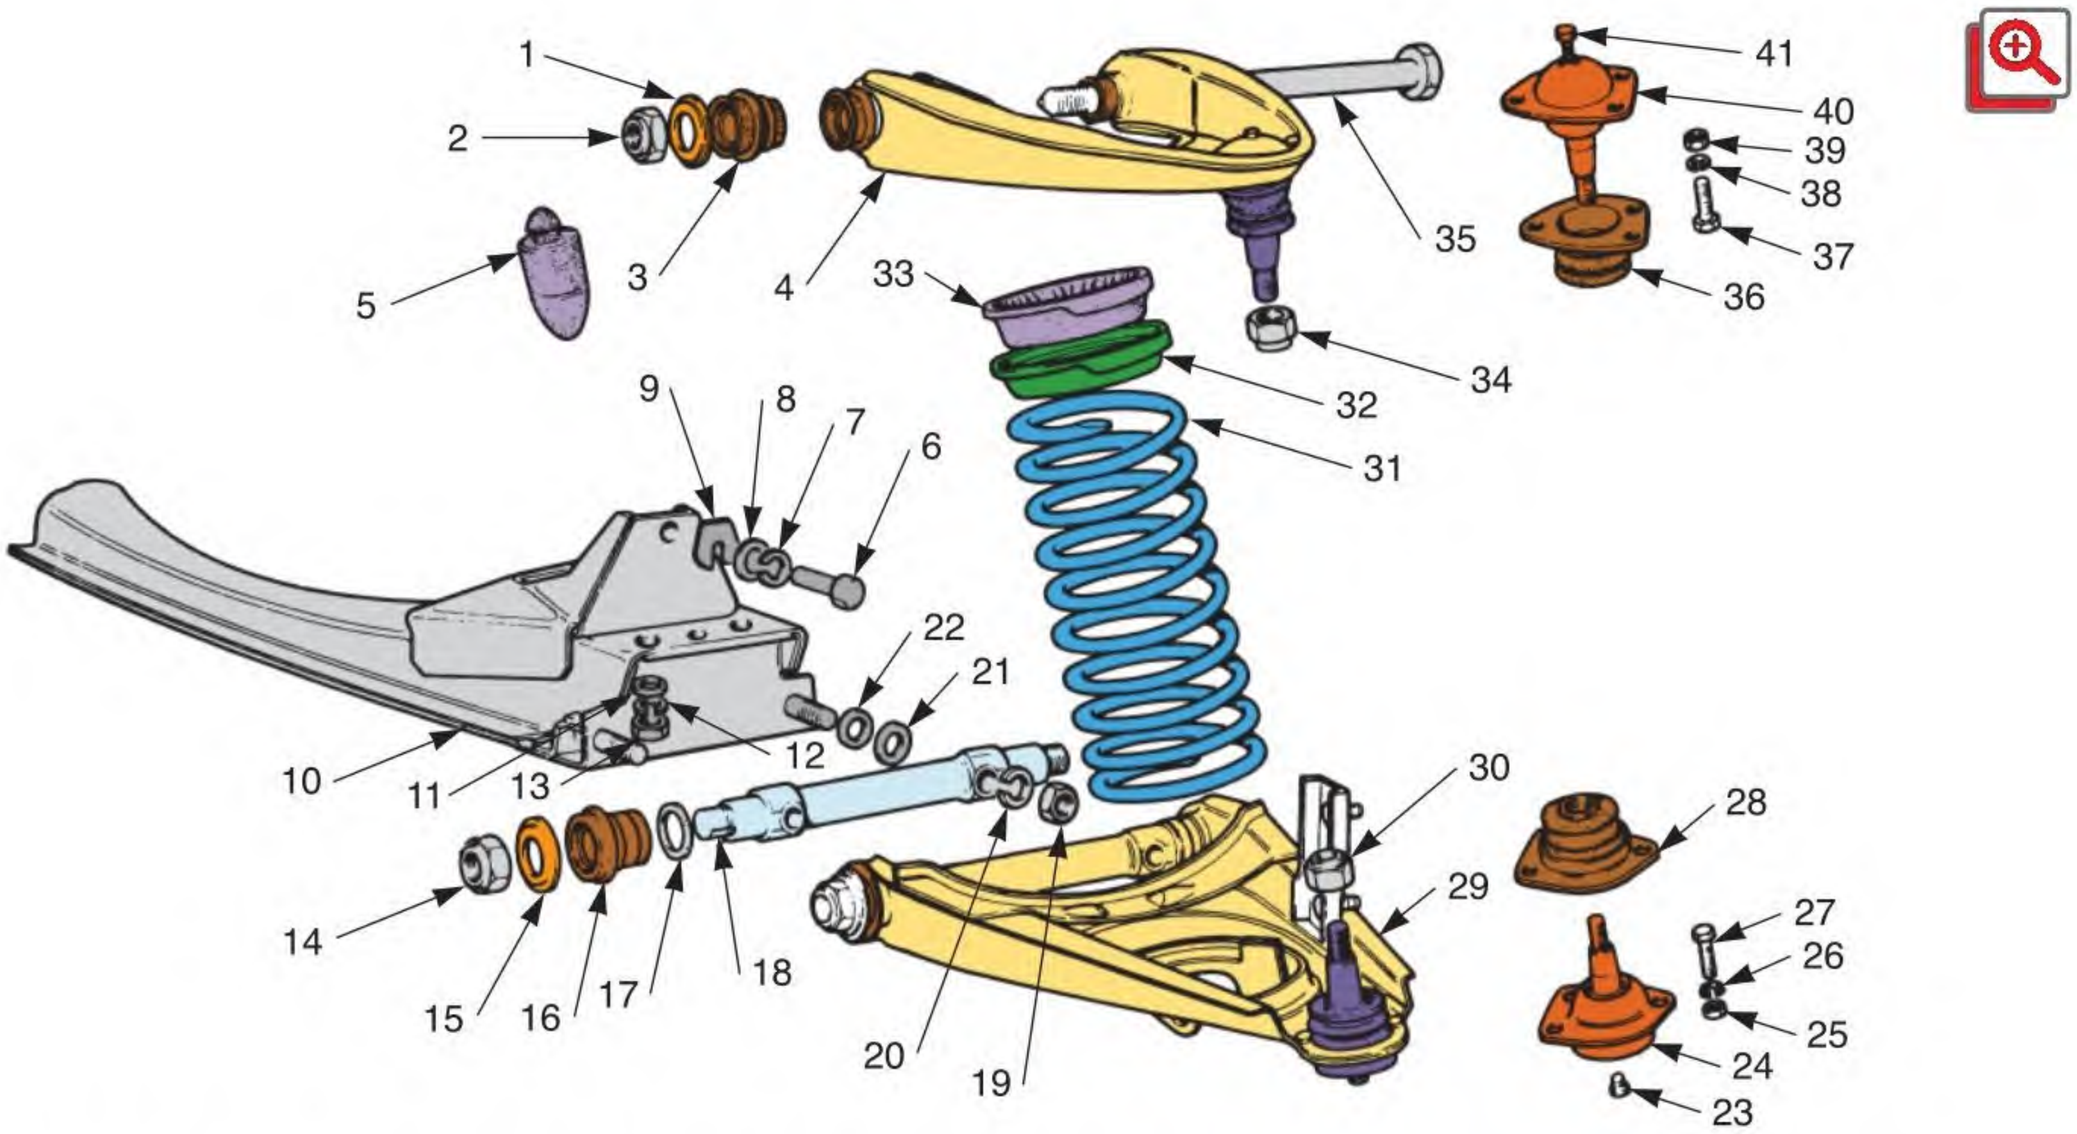
Worn control arm bushings can let the control arms move sideways, causing tire wear and steering problems. **Figure 76-15** shows the various bushings used on a front suspension. **Figure 76-16** pictures the bushings used on a rear suspension system.

Checking Bushing Wear

To check for bushing wear, try to move the control arm against normal movement while watching the bushings. If the arm moves in relation to its shaft, the bushings are worn and must be replaced.

Sticktion

Sticktion is a term used to describe the initial resistance to movement between rubber seals or bushings and metal parts. Engineers try to keep sticktion to a minimum. For example, sticktion afflicts suspension system bushings and shock absorber seals. Sticktion resists initial motion and affects ride smoothness.



Sticktion often causes old, dry, hardened bushings to make a loud squeaking noise when moved. This noise is caused by the high-frequency vibration set up in the bad bushing.

Tech Tip

With worn bushings, you might have heard sticktion. It makes a loud squealing sound when you bounce the body of the vehicle and slowly move the worn, sticking bushings.

Bushing Replacement

Exact procedures for installing new suspension system bushings vary. Refer to a service manual for exact directions to ensure a safe, quality repair.

Upper seating ring. 31. Upper rubber ring-pad. 32. Rubber buffer.

Fiat

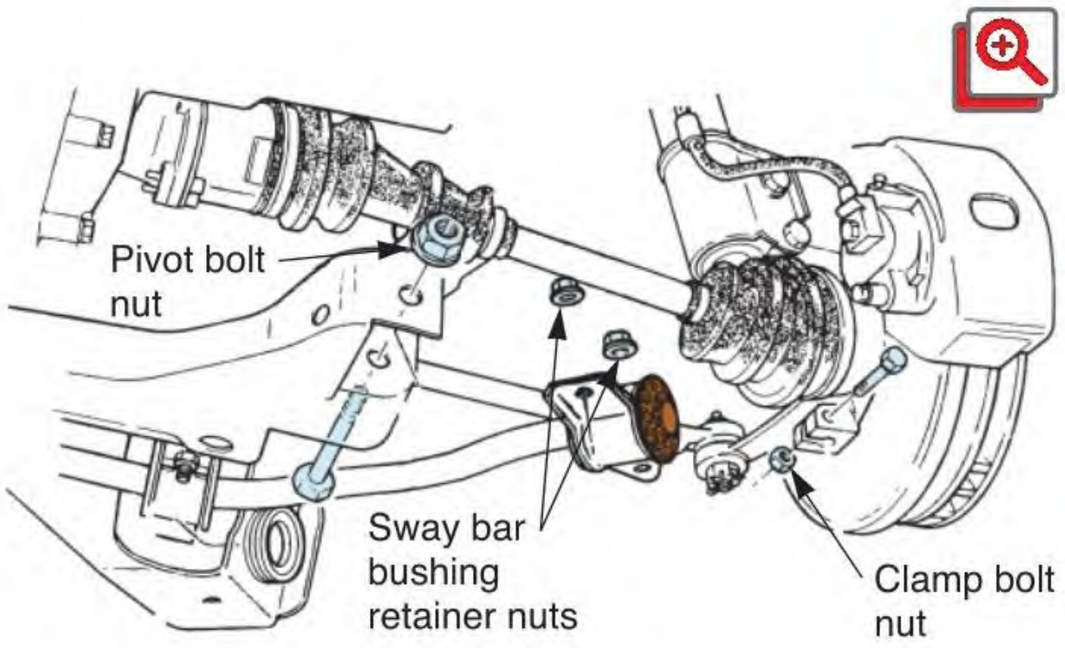
Figure 76-16. Exploded view shows bushings on one type of rear suspension.

Service Procedure

To replace bushings:

1. Remove the control arm when replacing the bushings in a front suspension. This usually requires ball joint separation and compression of the coil spring.
2. Unbolt the stabilizer bar and strut rod from the control arm.
3. Remove the bolts that pass through the bushings, **Figure 76-17**.
4. Mount the control arm in a vise.
5. Either press or screw out the old bushings. **Figure 76-18** shows a bushing driver, which can be used to press a bushing into and out of a control arm.
6. Install the control arm in the reverse order of removal.
7. Torque all bolts properly.
8. Install the ball joint cotter pin and other components.

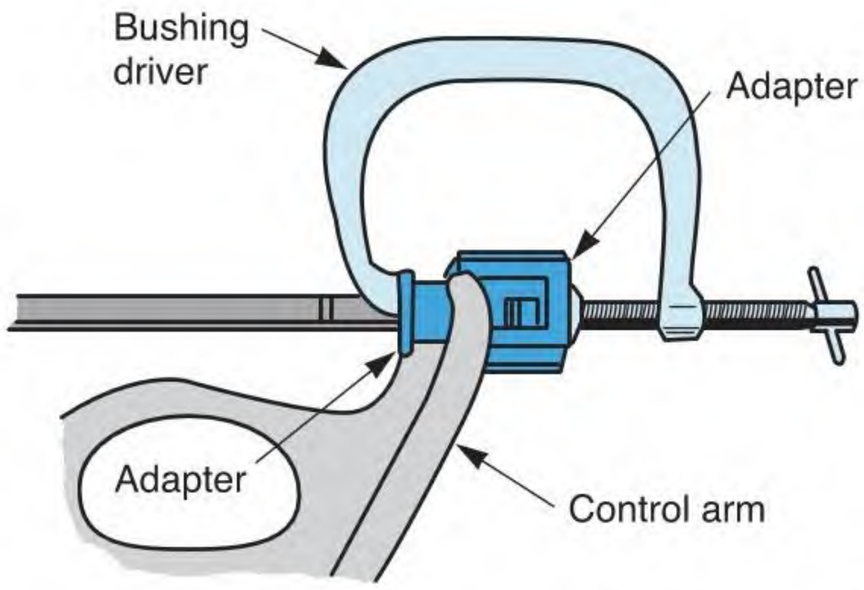
The procedure for preloading the control arm bushings depends on their design. Check the service manual for detailed instructions. Generally, you must install the bushing and lightly torque the nuts on the control arm shaft (if used). Then the weight of the vehicle is lowered onto the suspension system. This places the control arms in their most common location or angle. Then, tighten and preload the control arm bushings fully.



Strut rod bushings and stabilizer (sway) bar bushings also require replacement when worn. Refer back to **Figure 76-17**.

MacPherson Strut Service

The MacPherson strut suspension can wear and cause problems similar to those covered for other types of suspension systems. The major difference in service procedures relates to how the strut assembly is disassembled and reassembled.



The most common trouble with a MacPherson strut suspension is worn strut shock absorbers. Like conventional shocks, the pistons and cylinders inside

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 76-17. Control arm bushing replacement requires control arm removal. Note the parts that must be disconnected on a front-wheel-drive vehicle.

Goodheart-Willcox Publisher

Figure 76-18. A bushing driver is helpful when removing or installing control arm bushings.

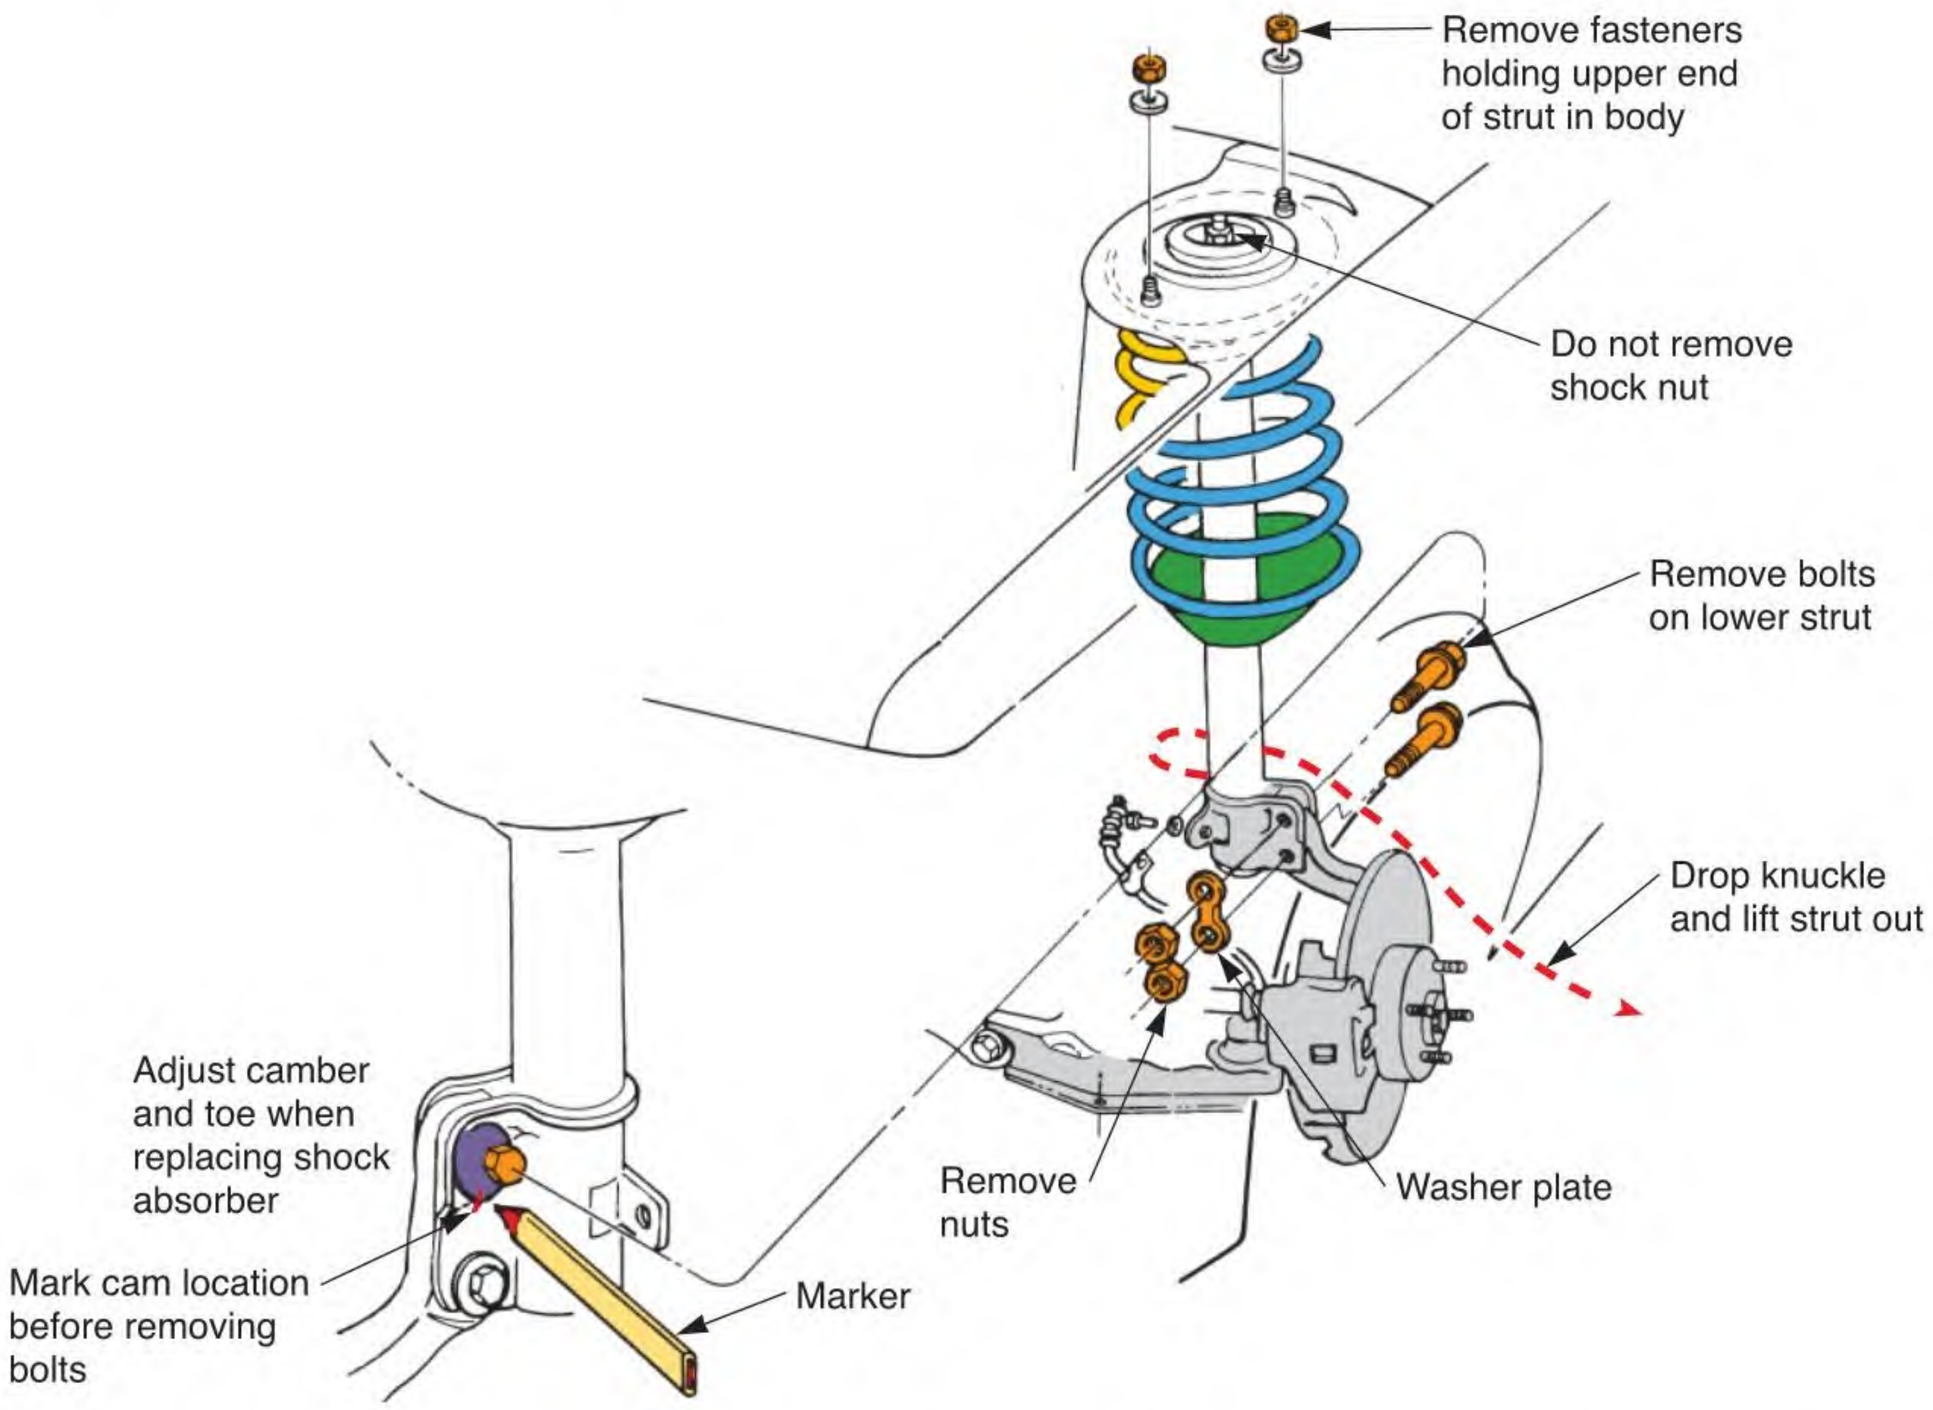
the strut shocks can begin to leak. This reduces the dampening action and causes the vehicle to ride poorly.

Strut Removal

Service Procedure

To remove a strut:

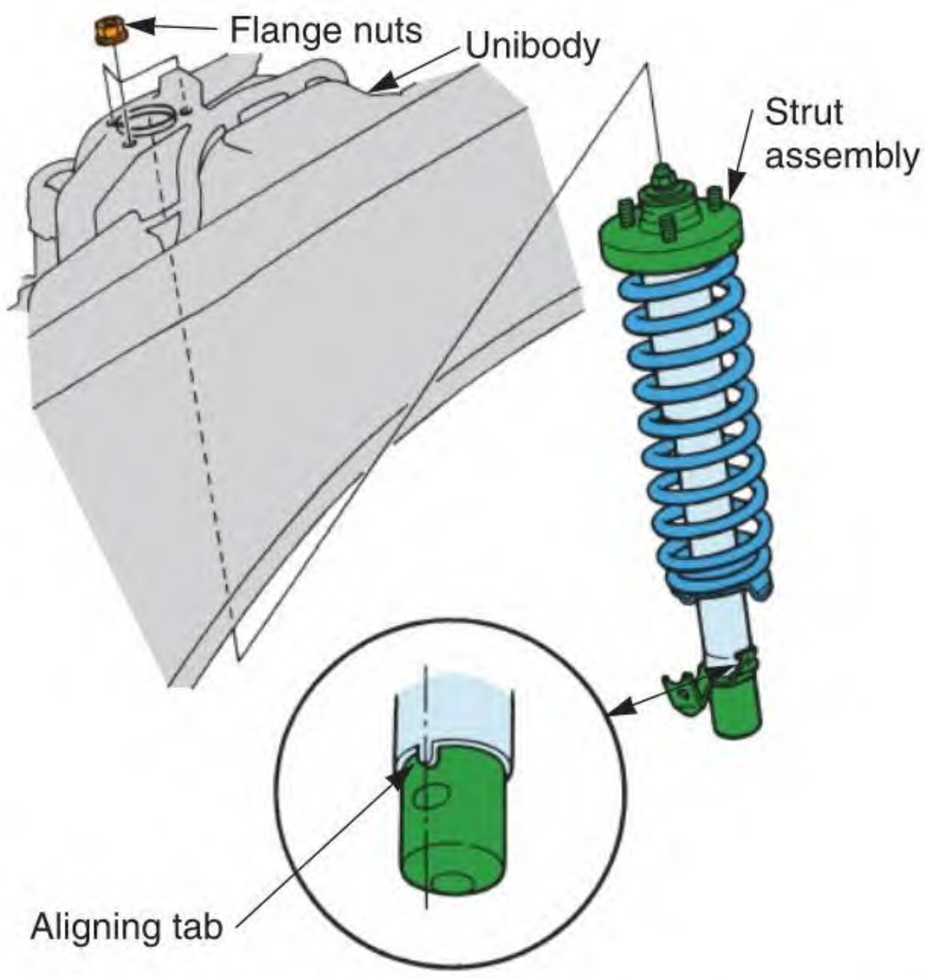
1. Raise and secure the car on stands or a lift to remove the vehicle weight from the suspension system.
2. Unbolt the steering knuckle (front) or bearing support (rear) from the strut.
3. If used, mark the cam bolt or knuckle with a scratch awl or marker to help during reassembly. You can realign this mark to roughly adjust camber. See **Figure 76-19**.
4. Disconnect the brake line if needed to avoid hose damage.
5. Separate the bottom end of the strut from its knuckle. Swing it to one side of the knuckle so it can drop down.
6. Unscrew the upper strut-to-body fasteners on the side of the engine compartment.
7. Remove the strut assembly (coil spring and shock) as a single unit, **Figure 76-20**.
8. Do not remove the nut on the end of the shock rod, or the unit could fly apart.



Strut Assembly Service

Strut assembly service generally involves replacing or rebuilding the strut shock absorber. Before removing the strut shock absorber, use a ***strut spring compressor*** to collapse the spring. Then, remove the coil spring from the strut. Look at **Figure 76-21**. After the coil spring has been squeezed together, remove the upper damper assembly. Then, release spring tension and lift the spring off the strut. Inspect all parts closely, **Figure 76-22**.

Warning



When compressing any suspension system spring, be extremely careful to position the compressor properly. If the spring were to pop out of the compressor, serious injury or death could result.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 76-19. Before removing a strut assembly, mark the cam-type bolt, if used. Remove the steering knuckle bolts and the upper fasteners from strut.

Honda

Figure 76-20. Carefully lift the strut out of the vehicle. Be ready to support its weight. Note how the unit aligns in the vehicle for easier reassembly.

Most automakers recommend replacing a faulty strut shock absorber (removable shock cartridge). The new shock simply screws into the strut's outer housing. A spanner wrench may be needed to turn the nut on the top of the cartridge. **Figure 76-23** shows a replacement shock absorber cartridge.

After replacing or rebuilding the strut shock absorber, fit the strut into the compressor and compress the coil spring. Then, install the upper spring seat and related components. After releasing the spring compressor, the strut can be installed on the vehicle.

Tech Tip

To safely dispose of gas-filled shocks, drill a small hole through the gas chamber. This will keep the shocks from possibly blowing up if burned or crushed. Wear eye protection when drilling to keep metal bits from flying in your face as the gas pressure is released from the chamber. Refer to **Figure 76-24**.

Copyright Goodheart-Willcox Co., Inc.

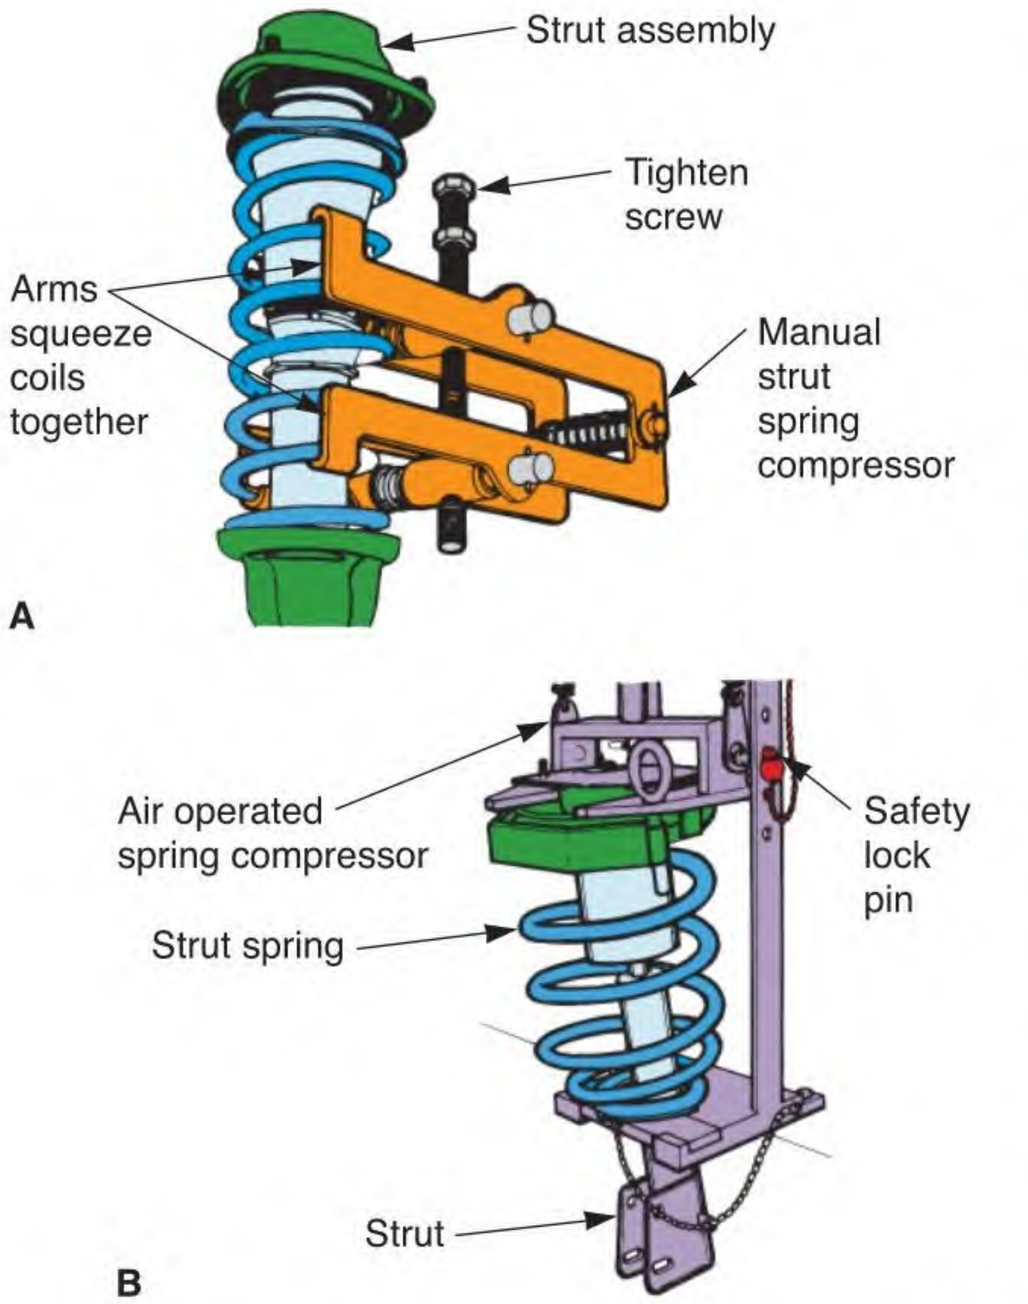


Figure 76-21. A spring compressor is needed to remove the spring from the strut assembly. A—Portable strut spring compressor. B—Bench-mounted strut spring compressor.

Strut Installation

Install the strut assembly in the reverse order of removal. See **Figure 76-25**. Lift the strut into position in the upper body mount. Attach the lower end of the strut to the steering knuckle or bearing support. Align your reference marks. Install the fasteners and torque them to specifications. Install any other parts and double-check your work.

Warning

Always torque all suspension systems bolts and nuts to factory specifications. This is essential for a competent, safe, dependable repair. If you fail to torque a suspension system fastener properly and the part disengages, a deadly auto accident could result. See **Figure 76-26**.

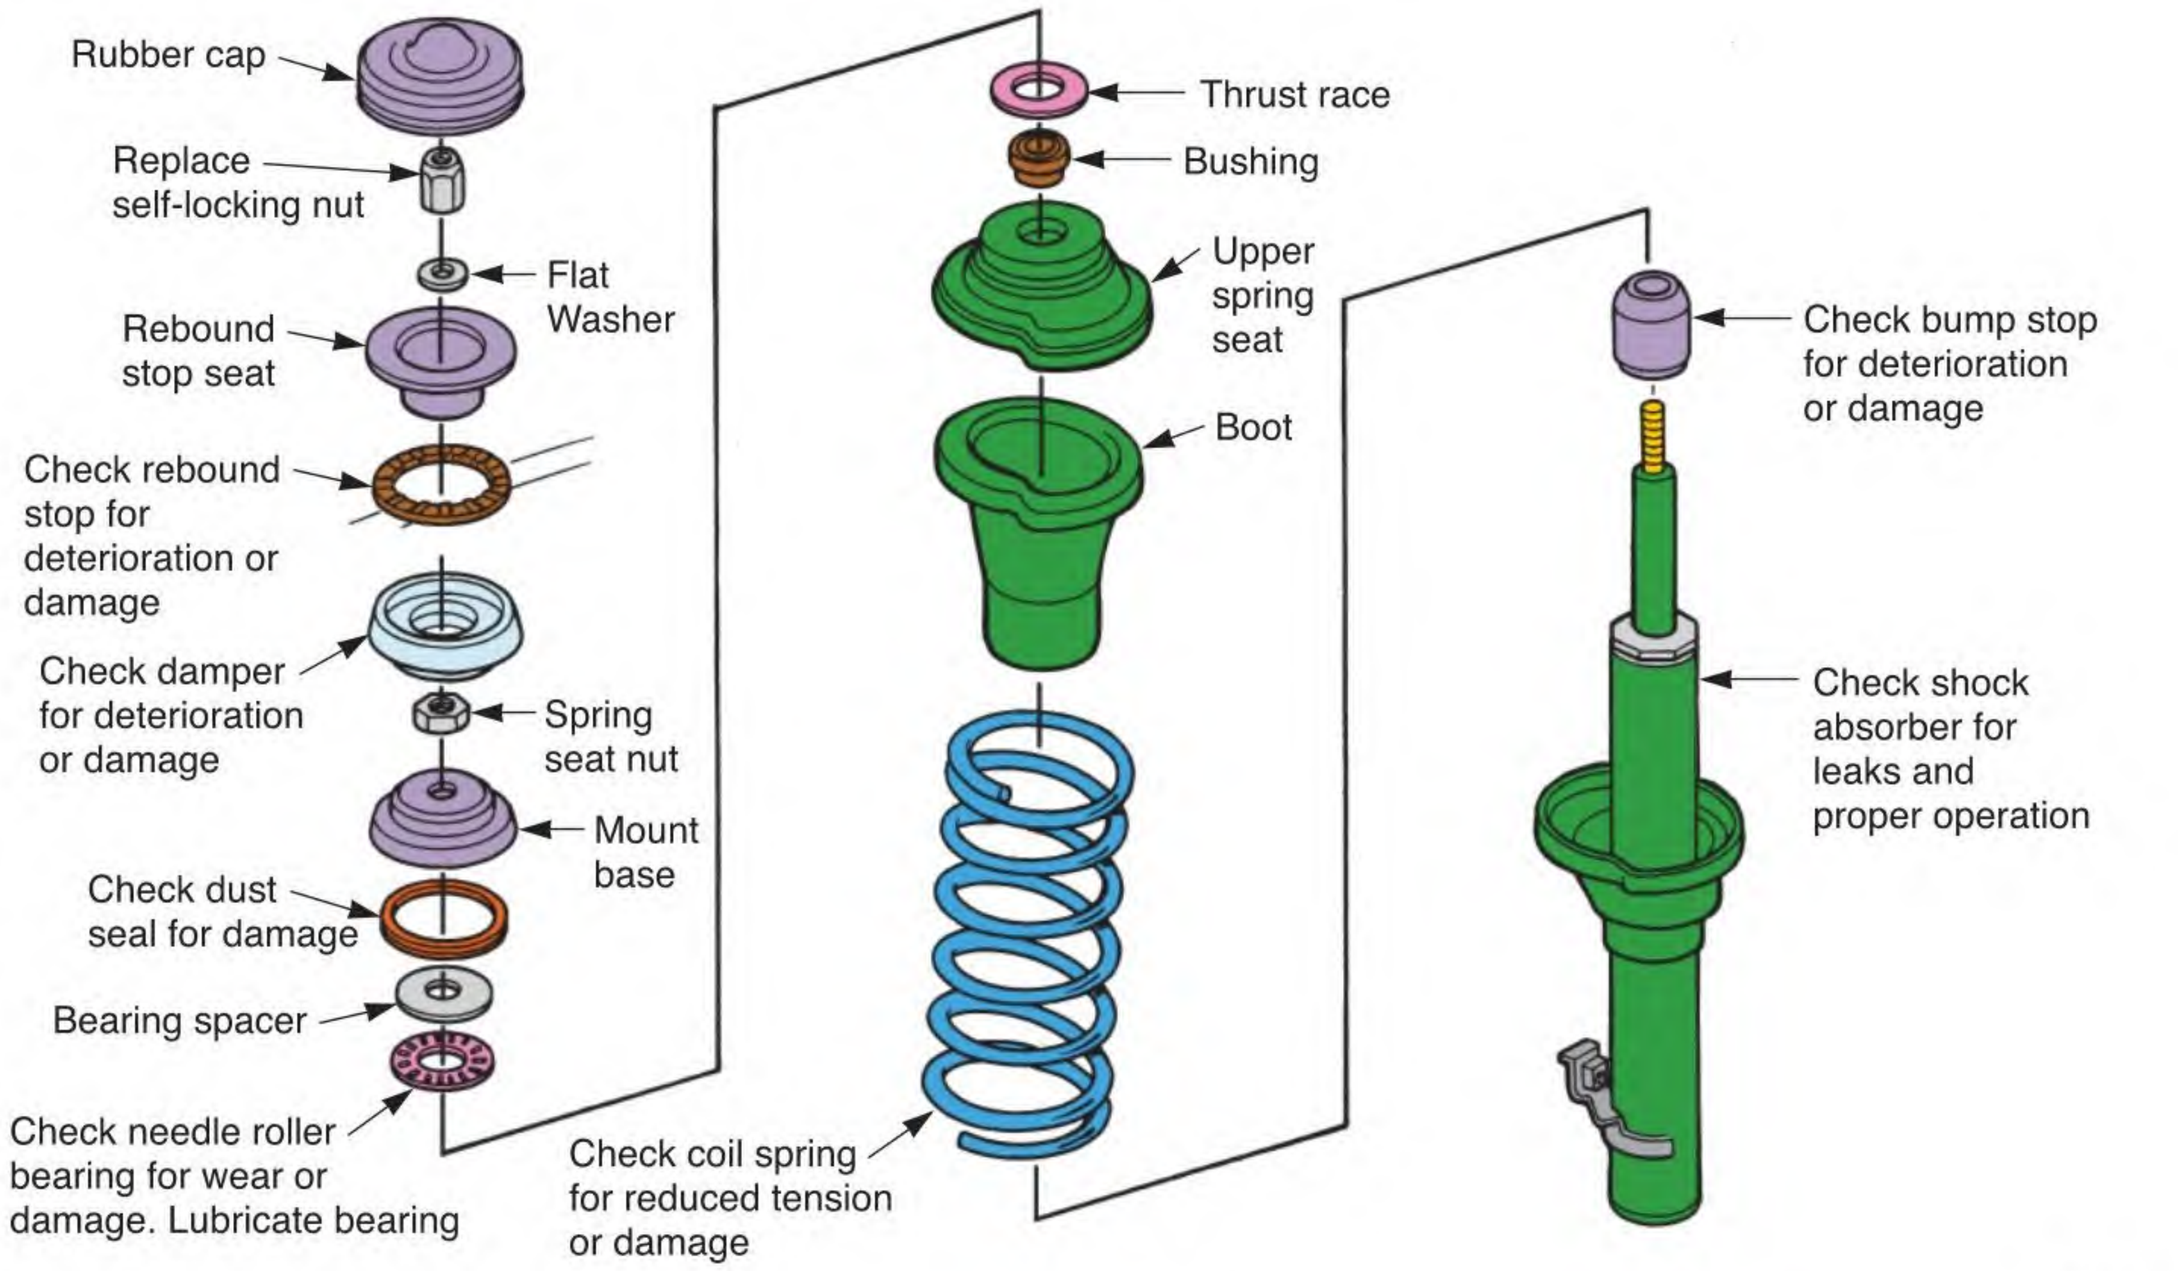
Wheel Alignment Is Needed

After servicing ball joints, control arm bushings, strut rods, springs, strut assemblies, or other suspension parts, wheel alignment must be checked and adjusted. *Never* let a vehicle leave the shop without checking alignment. Rapid tire wear or handling problems could occur.

Computerized Suspension Diagnosis

Discussed in the previous chapter, many modern suspension systems use some means of computer control to maintain ride height, adjust suspension system stiffness, and improve handling. A wiring diagram for an electronic suspension system is given in **Figure 76-27**.

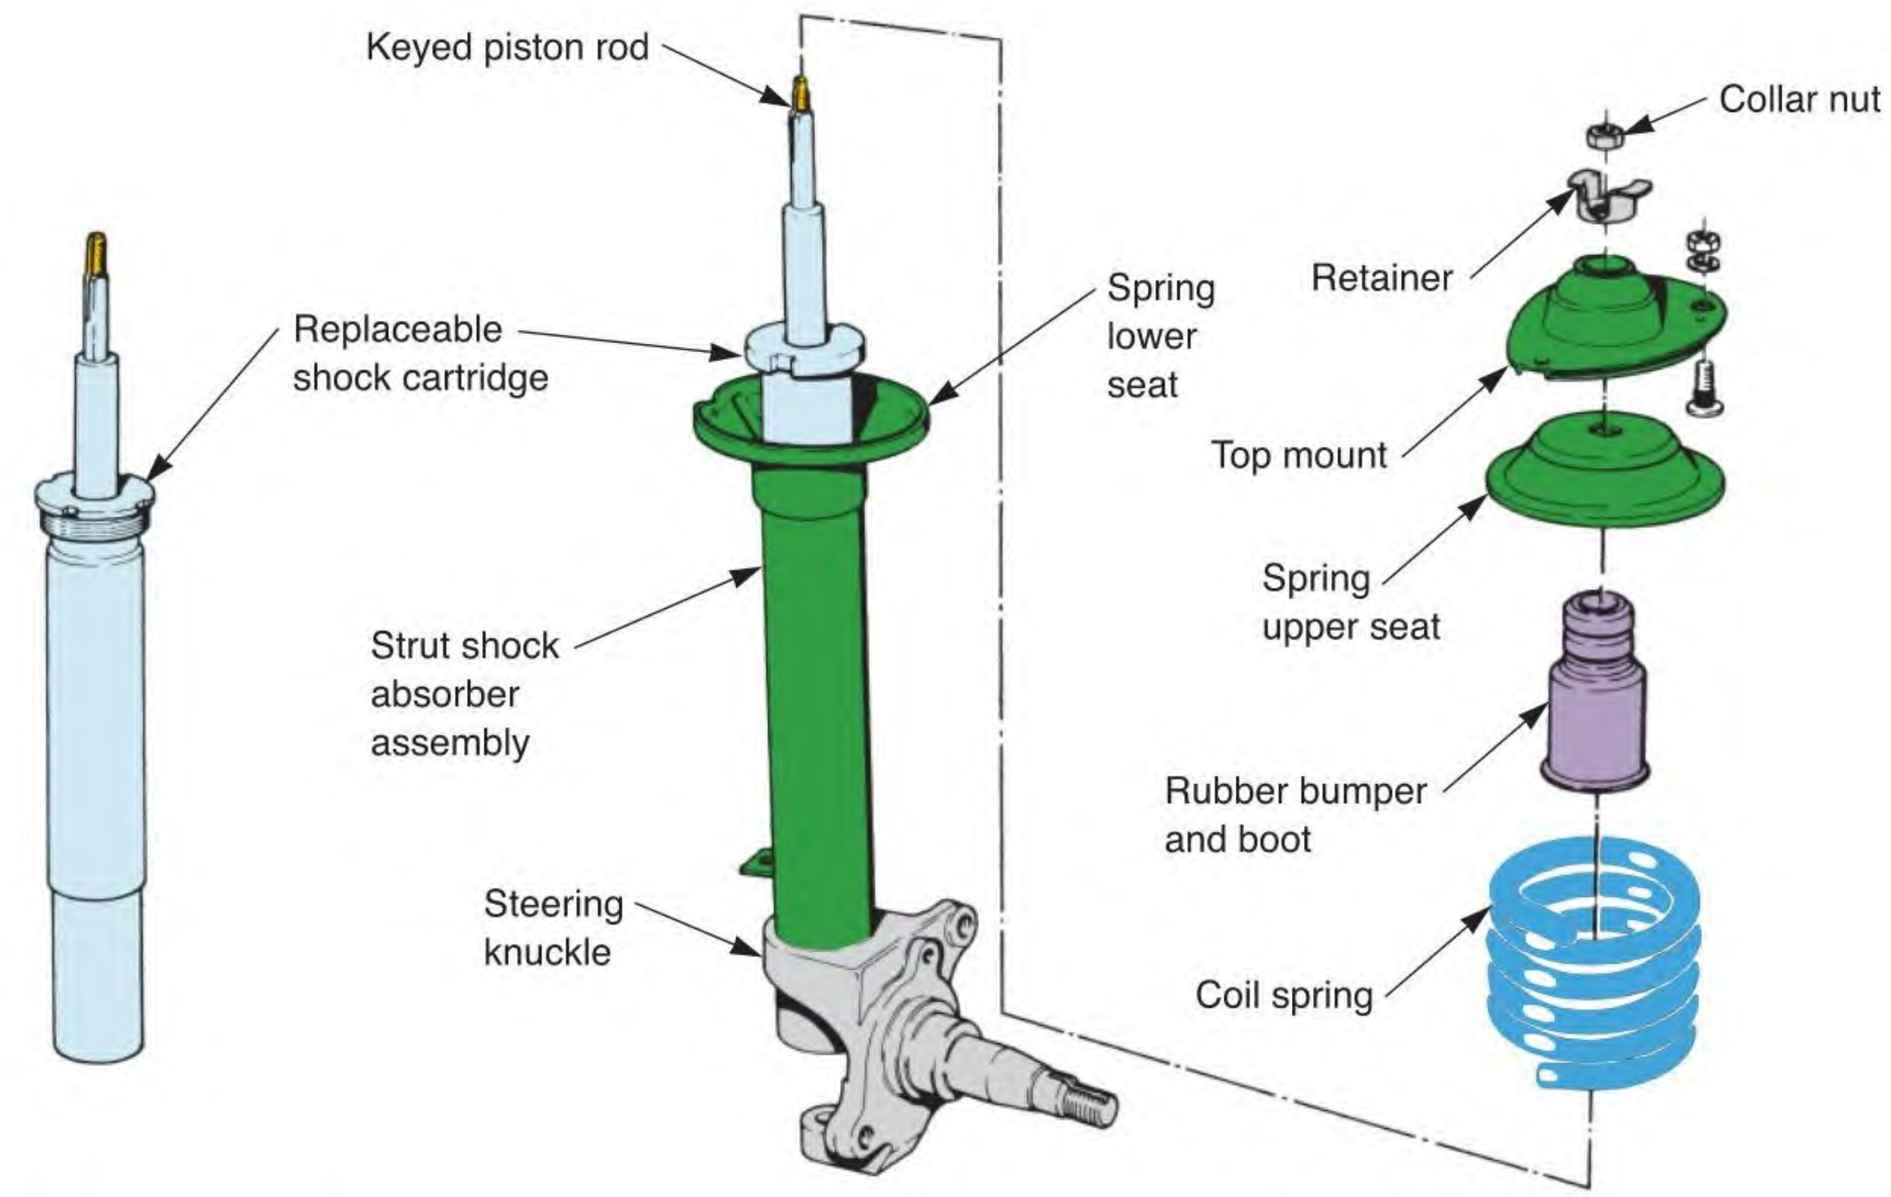
To start troubleshooting a computer-controlled suspension, connect a scan tool or diagnostic table to the vehicle's diagnostic connector. Read any stored diagnostic trouble codes and check operating values for all suspension-related components. Look at **Figure 76-28**.



Your scan tool might find problems with the following parts: solenoids and sensors, shock actuator motor, electrical relays, height sensors, compressor motor, and other electrical or electronic suspension components.

If the scan tool indicates a possible problem with a certain part or circuit, use pinpoint multimeter tests to verify the exact source of the trouble. For example, if the scan tool indicates a problem with the height sensor, use a VOM to test the unit's output in different positions, **Figure 76-29**.

Height Sensor Service



A faulty height sensor will fail to produce a normal output signal for each lever or height position. The sensor can fail mechanically due to worn parts, a bent arm, or broken parts. It can also fail electrically, ceasing to produce a normal signal. Replace the sensor if it does not work properly and cannot be adjusted.

Mazda

Figure 76-24. Before discarding gas-filled shocks, you should drill a small hole in the gas chamber to release the gas pressure. Wear face protection and follow service manual details.

Toyota

Figure 76-25. This exploded view shows how strut parts fit together.

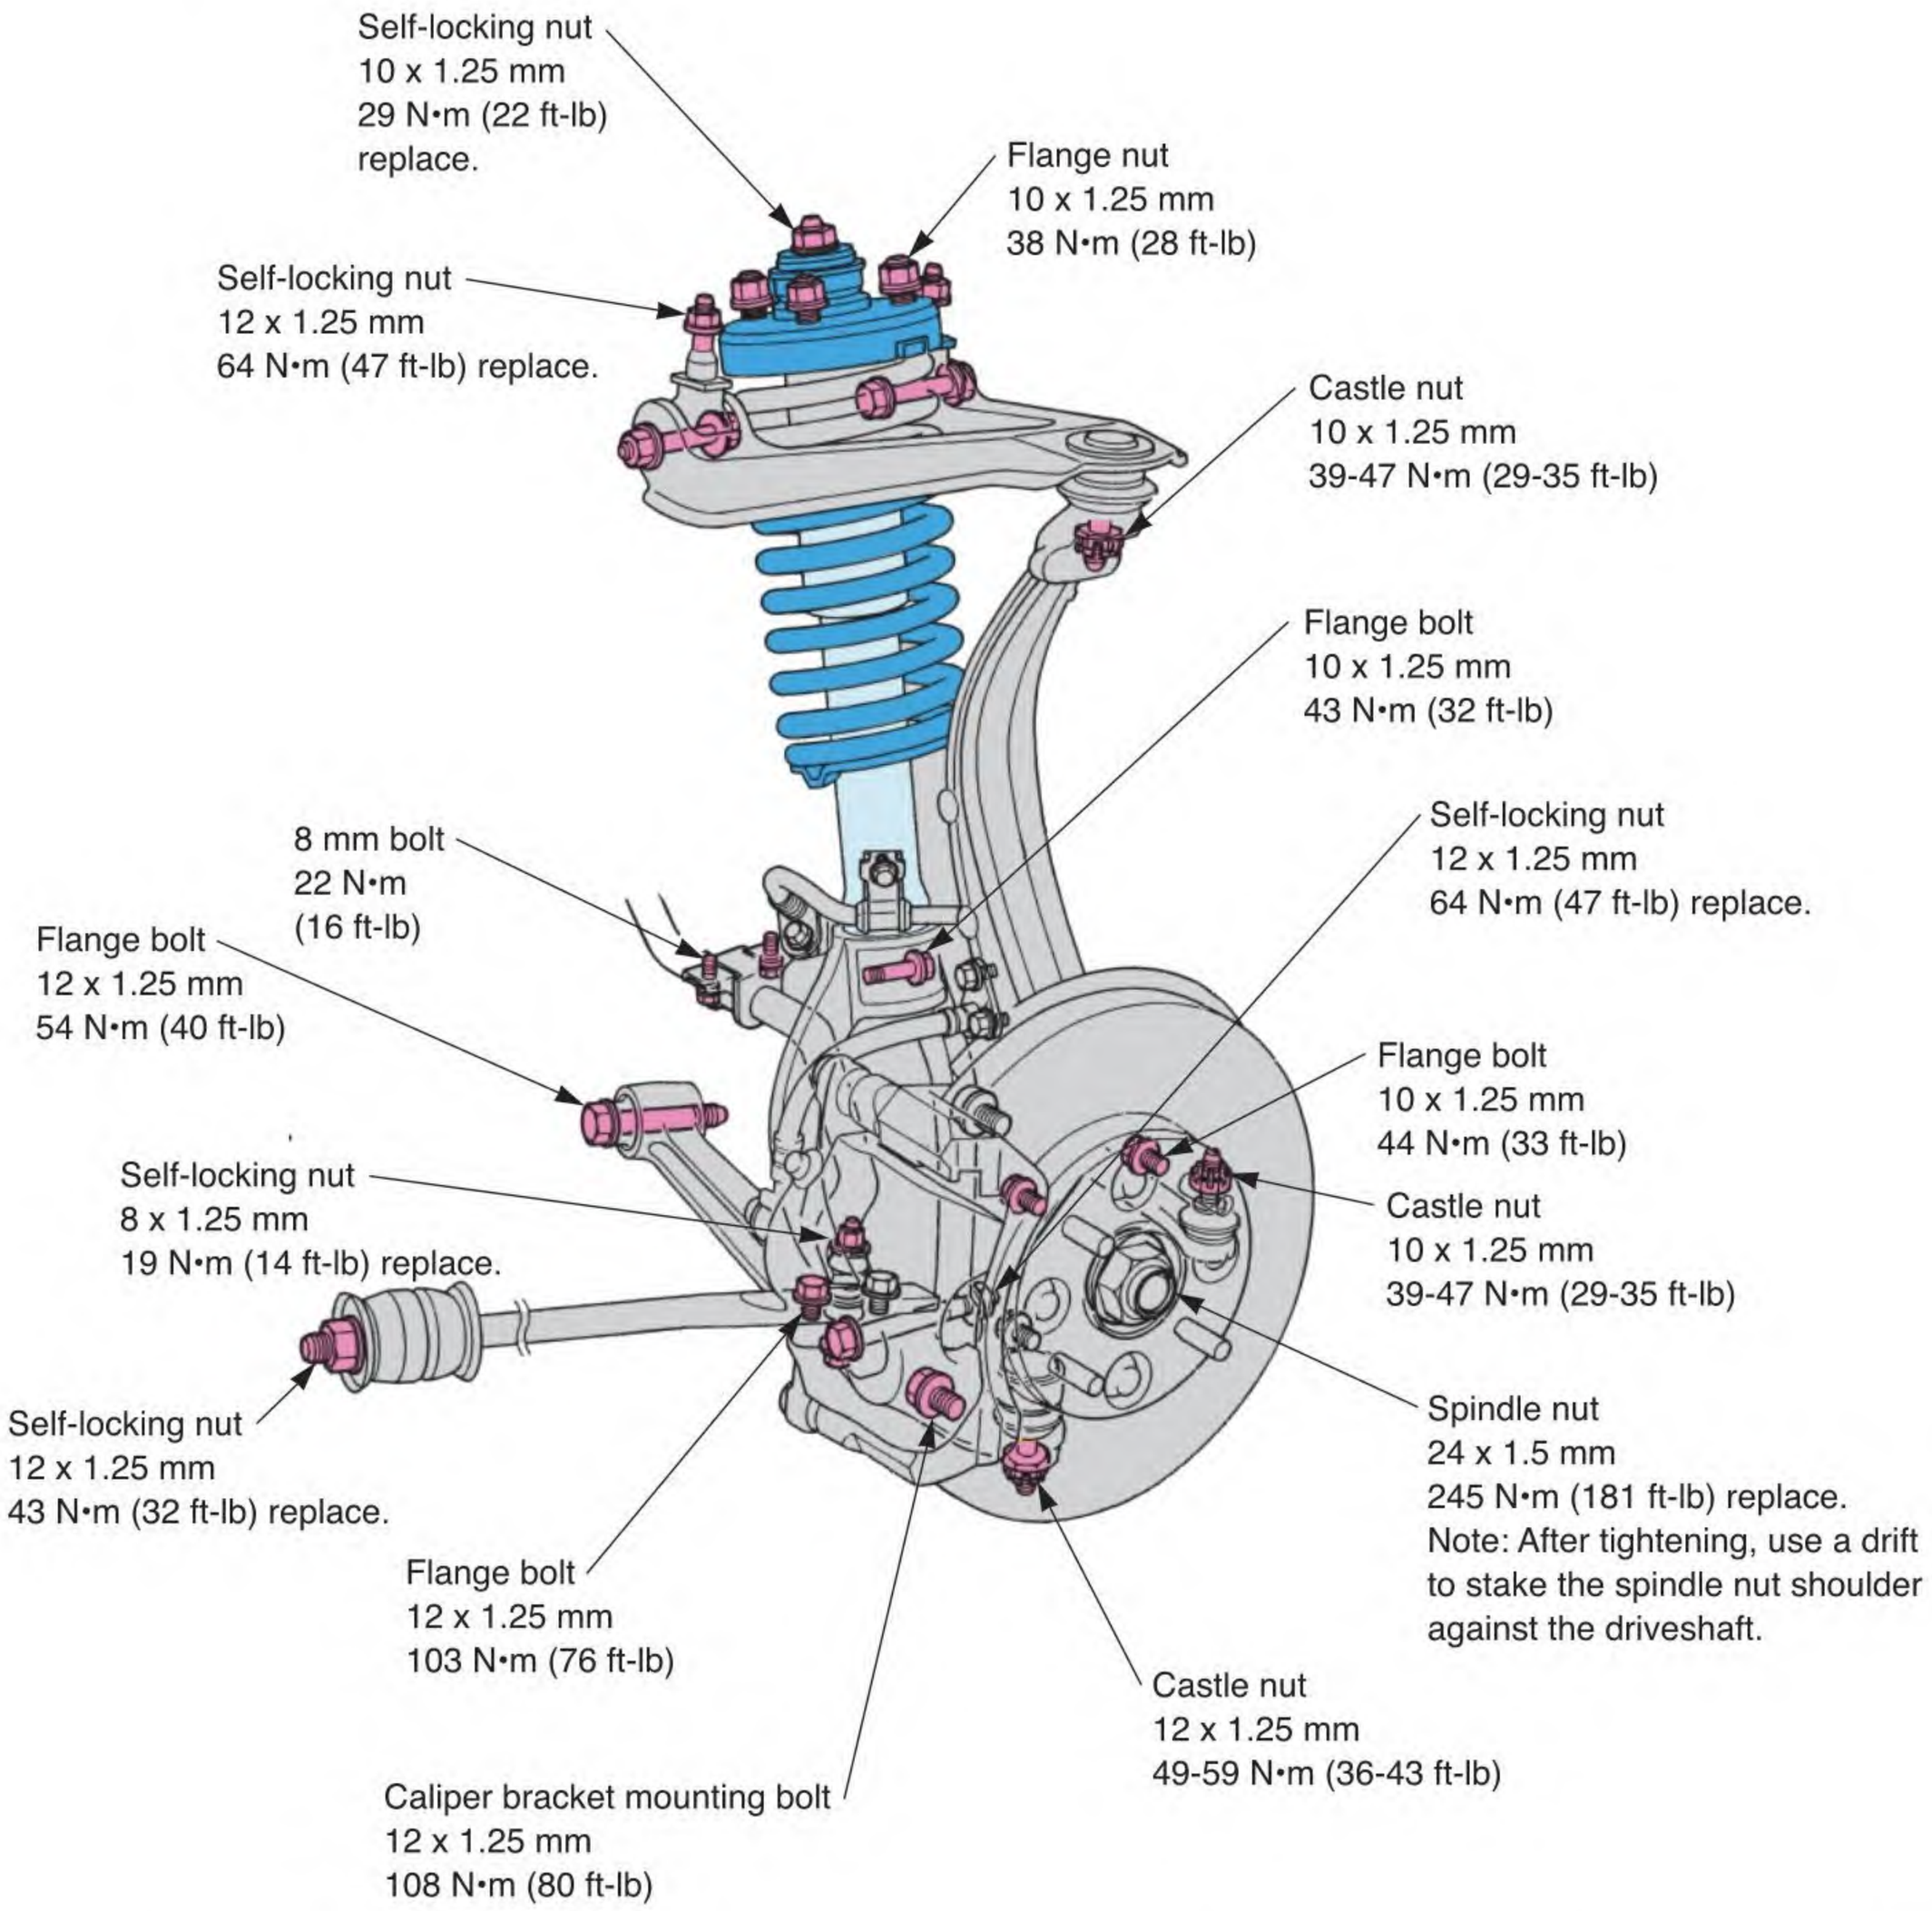
Compressor Service

A faulty compressor will not produce the air pressure needed to maintain the correct ride height. First check the compressor's electrical connections and its source of voltage. Then, connect a pressure gauge to the output hose fitting to measure the compressor's pressure output. If the pressure reading is not within specs, replace the compressor.

Electronically-Controlled Shock Service

When replacing the shocks on electronic suspension systems, you may be able to transfer some of the electronic parts from the old units onto the new ones. If you try to install conventional shocks to save the customer money, it could confuse the computer and cause constant trouble codes and other problems. Do not try to modify electronic suspension systems without the manufacturer's guidance.

Diagnostic Case Study



Concern: Mr. Brown brings his 2010 Kia Sedona to the shop. He complains that his minivan is making a loud popping or knocking sound when turning corners.

Cause: Duff takes the van for a test-drive and hears a deep-pitched knocking or clunking sound coming from the right front of the vehicle during turns. He speculates that the loud deep knock must be coming from a large suspension or steering part, like a ball joint. Smaller suspension and steering parts would make higher-pitched or lighter knocking sound.

Duff turns the car over to the shop's suspension and steering technician. The technician raises the car and unloads the ball joints. He positions a pry bar under one front tire and wiggles the suspension. He notes that there is excessive play in the lower ball joint. He then repeats the procedure on the other wheel.

Correction: The technician removes the front shock absorbers and removes the coil springs with a spring compressor. He then removes the steering knuckles. He bolts new ball joints to the control arms and reassembles the suspension parts. After reassembly, the technician corrects vehicle wheel alignment and then takes the car for a brief test drive. The noises are eliminated, and the vehicle is released to the owner.

Figure 76-29. Pinpoint tests are needed to locate the exact source of trouble. A—A handheld scope checks the output signal from a height sensor. Voltage should steadily increase and decrease as the sensor arm is moved up and down. B—This voltage waveform is for a typical height sensor. If there are spikes or abnormal voltages, check the reference voltage before replacing the sensor.

Summary

- A suspension system takes a tremendous pounding during normal vehicle operation. Bumps and potholes in the road cause constant movement, fatigue, and wear of shock absorbers, ball joints, bushings, springs, and other parts.
- Make sure that the suspected troubles are actually in the suspension system, *not* in the steering, wheel bearings, tires, or other related parts.
- Worn shock absorbers cause a vehicle to ride poorly on rough roads.
- Generally, good shock absorbers should stop body movement in one or two rebounds.
- Spring fatigue (weakening) lowers the height of the vehicle, allowing the body to settle toward the axles.
- To check spring condition, measure the vehicle's curb height.
- A coil spring compressor may be needed when removing and installing a coil spring.
- Worn ball joints cause the steering knuckle to be loose on the control arms.
- A grease gun is used to inject chassis grease into the ball joint grease fittings.
- Worn control arm bushings can allow the control arms to move sideways, causing tire wear and steering problems.
- Sticktion is a term used to describe the initial resistance to movement between rubber seals or bushings and metal parts.
- Most automakers recommend that faulty strut or shock cartridges be replaced.

Copyright Goodheart-Willcox Co., Inc.

- To safely dispose of gas-filled shocks, drill a small hole through the gas chamber.
- Always torque all suspension system bolts and nuts to factory specifications.
- The first step in troubleshooting a computer-controlled suspension is to connect a scan tool or diagnostic tablet to the vehicle's diagnostic connector.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

ball joint separator
ball joint wear indicator
coil spring compressor
curb height
curb weight
fork tool
grease gun
shock absorber bounce test
spring fatigue
sticktion
strut spring compressor

Activities

1. Measure a vehicle for proper curb height after checking curb weight.
2. Inspect ball joints for wear and report their condition to your instructor.
3. Inspect and test-drive a vehicle with suspension problems. Diagnose the problem and suggest what service is needed.
4. Prepare a bill for a customer for replacement of front struts. Base your bill on an hourly charge rate established by your instructor. Find the cost of parts from a manufacturer's online parts catalog or by searching an automotive parts store's website. Use a flat rate manual on the shop's computer to find repair time.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List several symptoms of common suspension system problems.
2. A customer complains that her vehicle's ride is very rough and the vehicle continues to rebound long after going over humps in the road. Technician A says that a bounce test is needed to check the shocks. Technician B says that a general inspection for worn suspension parts is also needed. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. What happens with spring fatigue?
4. Define the terms *curb height* and *curb weight*.
5. A(n) _____ is needed to remove and install a suspension system coil spring.
6. Why is suspension spring removal dangerous?
7. A(n) _____ tool or _____ is needed to force the ball joint stud from the steering knuckle.
8. How do you check for ball joint wear?
9. Generally, how do you remove a strut assembly?
10. Which of the following is *not* normally needed during strut service?
    (A) Shock or strut cartridge.
    (B) Jack stands or a car lift.
    (C) Spring compressor.
    (D) Air chisel.

Copyright Goodheart-Willcox Co., Inc.

ASE-Type Questions

1. A car with an electronic air suspension is brought into the shop with an air compressor problem. Technician A checks the compressor's electrical connections and its source of voltage. Technician B tests the compressor's output pressure with a pressure gauge. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. A car's wheel alignment angles are not within specifications. Technician A checks the condition of the ball joints. Technician B looks for worn control arms bushings. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. All the following are typical automotive suspension system problems *except:*
   (A) bad control arm bushings.
   (B) damaged flex plate.
   (C) worn strut rod bushings.
   (D) bad ball joints.
4. A customer brings an automobile into the shop with a rough ride complaint. Technician A looks for worn strut shock absorbers. Technician B checks the condition of the strut mounting nuts. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. A vehicle's body bounces five times after a "shock bounce test" is performed. Technician A says this indicates that the shocks are in good condition. Technician B says the results of this test indicate bad shock absorbers. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. A small pickup truck is brought into the shop with a leaking shock absorber. Technician A says the leaking shock will produce a high-pitch screeching noise when the vehicle is driven. Technician B says that the leaking shock must be replaced. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. A car's strut shock absorbers are being replaced. During the procedure, Technician A says jack stands must be placed under the vehicle's strut assemblies. Technician B says jack stands should be placed under the axles. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. One of an automobile's air shocks is leaking. Technician A says that exceeding the recommended maximum air pressure given for air shocks is safe and smoothes operation. Technician B says the shock's air line can be repaired if it is leaking. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. A customer wants to know why his car's wheels are out of alignment. Technician A says weak suspension system springs can affect an automobile's wheel alignment. Technician B says vehicle suspension problems cannot cause wheel misalignment. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. A car's curb weight is being measured. Technician A checks curb weight with the automobile's gas tank empty. Technician B checks curb weight with the automobile's gas tank full. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

11. A truck's coil springs are being replaced (spring over control arm). During this procedure, Technician A unbolts the ball joint before compressing the coil spring. Technician B compresses the coil spring before unbolting the ball joint. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. Technician A says leaf springs are used in many late-model vehicles because they cannot break. Technician B says a spring compressor is not always required when replacing a rear coil spring. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. A car is brought into the shop with a possible ball joint problem. Technician A uses a ball joint wear indicator to check the condition of the automobile's ball joints. Technician B jacks up the vehicle and moves the control arm and joint. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. A car's front tires are worn. Technician A tells the car's owner that worn control arm bushings may have caused this problem. Technician B tells the owner that worn control arm bushings do not affect tire wear. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
15. An automobile's ball joints have been replaced. After performing this procedure, Technician A says the vehicle should be road tested before further adjustments are made. Technician B says the vehicle's wheel alignment should be checked before the vehicle is road tested. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Suspension System Diagnosis

Condition	Possible Causes	Correction
Front end whines on turns.	1. Defective wheel bearing. 2. Incorrect wheel alignment. 3. Worn tires.	1. Replace wheel bearing. 2. Check and reset wheel alignment. 3. Replace tires.
Front end growl or grinding on turns.	1. Defective wheel bearing. 2. Engine mount grounding. 3. Worn or broken CV-joint. 4. Loose lug nuts. 5. Incorrect wheel alignment. 6. Worn tires.	1. Replace wheel bearing. 2. Check for motor mount hitting frame rail and reposition engine as required. 3. Replace CV-joint. 4. Verify wheel lug nut torque. 5. Check and reset wheel alignment. 6. Replace tires.
Front end clunk or snap on turns.	1. Loose lug nuts. 2. Worn or broken CV-joint. 3. Worn or loose tie-rod, ball joint, control arm bushing, sway bar, or upper strut attachment. 4. Loose crossmember bolts.	1. Verify wheel lug nut torque. Tighten as necessary. 2. Replace CV-joint. 3. Tighten or replace tie-rod end or ball joint; replace control arm bushing; tighten sway bar or upper strut attachment to specified torque. 4. Tighten crossmember bolts to specified torque.
Front end whine with vehicle going straight at a constant speed.	1. Defective wheel bearing. 2. Incorrect wheel alignment. 3. Worn tires. 4. Worn or defective transaxle gears or bearings.	1. Replace wheel bearing. 2. Check and reset wheel alignment. 3. Replace tires. 4. Replace transaxle gears or bearings.
Front end growl or grinding with vehicle going straight at a constant speed.	1. Engine mount grounding. 2. Worn or broken CV-joint.	1. Reposition engine as required. 2. Replace CV-joint.
Road wander.	1. Incorrect tire pressure. 2. Incorrect wheel toe. 3. Worn wheel bearings. 4. Worn control arm bushings. 5. Excessive friction in steering gear. 6. Excessive friction in steering shaft coupling. 7. Excessive friction in strut upper bearing.	1. Inflate tires to recommended pressure. 2. Check and reset front wheel toe. 3. Replace wheel bearing. 4. Replace control arm bushing. 5. Replace steering gear. 6. Replace steering coupling. 7. Replace strut bearing.
Lateral pull.	1. Unequal tire pressure. 2. Radial tire lead. 3. Incorrect front wheel camber. 4. Power steering gear imbalance. 5. Wheel braking.	1. Inflate tire to recommended pressure. 2. Perform lead correction procedure. 3. Check and reset front wheel camber. 4. Replace power steering gear. 5. Correct braking condition causing lateral pull.
Excessive steering effort.	1. Low tire pressure. 2. Lack of lubricant in steering gear. 3. Low power steering fluid level. 4. Loose power steering pump belt. 5. Lack of lubricant in steering ball joints. 6. Steering gear malfunction. 7. Lack of lubricant in steering coupler.	1. Inflate all tires to recommended pressure. 2. Replace steering gear. 3. Fill power steering fluid reservoir to correct level. 4. Correctly adjust power steering pump belt. 5. Lubricate or replace steering ball joints. 6. Replace steering gear. 7. Replace steering coupler.

Chapter 77
Steering System Technology

After studying this chapter, you will be able to:

- Explain the operating principles of steering systems.
- Identify the major parts of a steering system.
- Compare the differences between a linkage steering and a rack-and-pinion steering system.
- Describe the operation of hydraulic and electric-assist power steering systems.
- Explain the operation of four-wheel steering systems.
- Correctly answer ASE certification test questions requiring a knowledge of modern steering system designs.

The steering system is vital to the safety of an automobile and its occupants. The steering wheel and its power transfer mechanisms allow the driver to safely maneuver the vehicle. To be a good diagnostic and repair technician, you must first understand the construction and operation of modern steering systems.

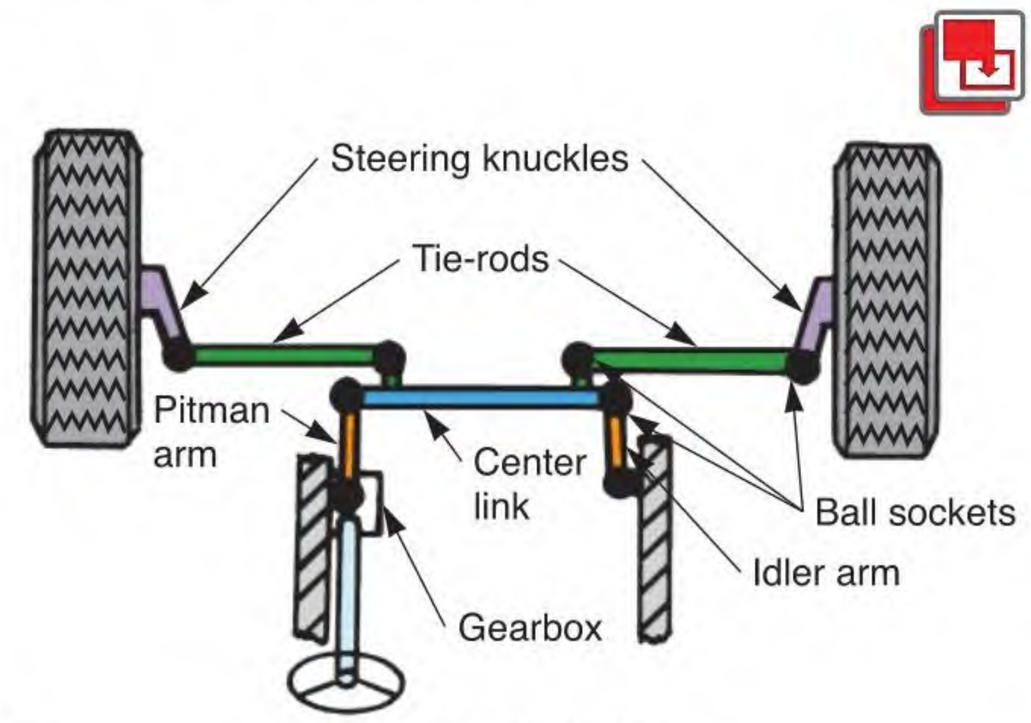
Early steering systems were simple mechanical mechanisms. A series of shafts, rods, and gears transferred steering wheel motion to the wheels and tires. Today's steering systems are much more sophisticated. They still use mechanical mechanisms for safety, but they also use hydraulics or electric motors and electronic circuits to improve steering ease and precision.

This chapter will build upon your knowledge of automotive technology by introducing late-model steering system variations. It will explain basic manual steering systems before progressing to more complex hydraulic-mechanical and electronic-mechanical designs.

Functions of a Steering System

A steering system must perform the following important functions:

- It provides precise control of the front-wheel direction and, sometimes, the rear-wheel direction.
- It maintains the correct amount of effort needed to turn the wheels.
- It transmits ***road feel*** (slight steering wheel pull caused by road surface irregularities) to the driver's hands.
- It absorbs most of the shock going to the steering wheel as the tires hit bumps and potholes in the road.



Copyright Goodheart-Willcox Co., Inc.

- It allows for suspension action with minimal effect on the direction and alignment of the front wheels of the vehicle.

Basic Steering Systems

There are two basic kinds of steering systems in wide use today: linkage (worm gear) and rack-and-pinion. ***Linkage steering systems*** are found on large, full-size pickup trucks and full-size vans, both two- and four-wheel drive. ***Rack-and-pinion steering systems*** are lighter and are better for passenger cars and small trucks. Each type may be operated manually or with power assist.

To effectively diagnose and repair steering systems, you must first understand the major parts of a steering system and their functions. This will allow you to develop a better "picture" of how each component operates. See **Figure 77-1**.

Goodheart-Willcox Publisher

Figure 77-1. There are two types of steering systems. Rack-and-pinion steering is found on passenger cars. Linkage steering is still used on full-size trucks, vans, and SUVs.

Basic Linkage Steering

The following are the parts that make up a linkage steering system:

- ***Steering wheel***—The steering wheel is used by the driver to rotate a steering shaft that passes through the steering column and firewall.
- ***Steering shaft***—The steering shaft consists of a long steel shaft that transfers turning motion from the steering wheel to the steering gearbox.
- ***Steering column***—The steering column is a hollow tube that supports the steering wheel and the steering shaft.
- ***Steering gearbox***—The steering gearbox changes turning motion into a straight-line motion (from left or right) for moving the steering knuckles.
- ***Steering linkage***—Steering linkage connects the steering gearbox to the steering knuckles and the wheels. Tie-rod assemblies are a part of the linkage.
- ***Ball sockets***—Ball sockets on the tie-rod ends are grease-filled swivel joints that allow linkage arms to swivel up and down (for suspension action) and from left to right (for turning).

Basic Rack-and-Pinion Steering

A rack-and-pinion steering system also uses a steering wheel, steering column, and steering shaft. These components transfer the driver's turning effort to gears in the steering gear assembly or steering rack.

Other than the parts just covered, the following are the major components of a rack-and-pinion steering system:

- ***Steering pinion gear***—This small gear is rotated by the steering wheel and steering shaft; its teeth mesh with the teeth on the rack.
- ***Rack***—The rack is a long steel bar with teeth along one section; it slides sideways in its housing as the pinion gear turns.
- ***Gear housing***—This housing holds the pinion gear and the rack.
- ***Tie-rods***—Tie-rods are steel rods with swivel sockets on each end that connect the rack with the two front steering knuckles.

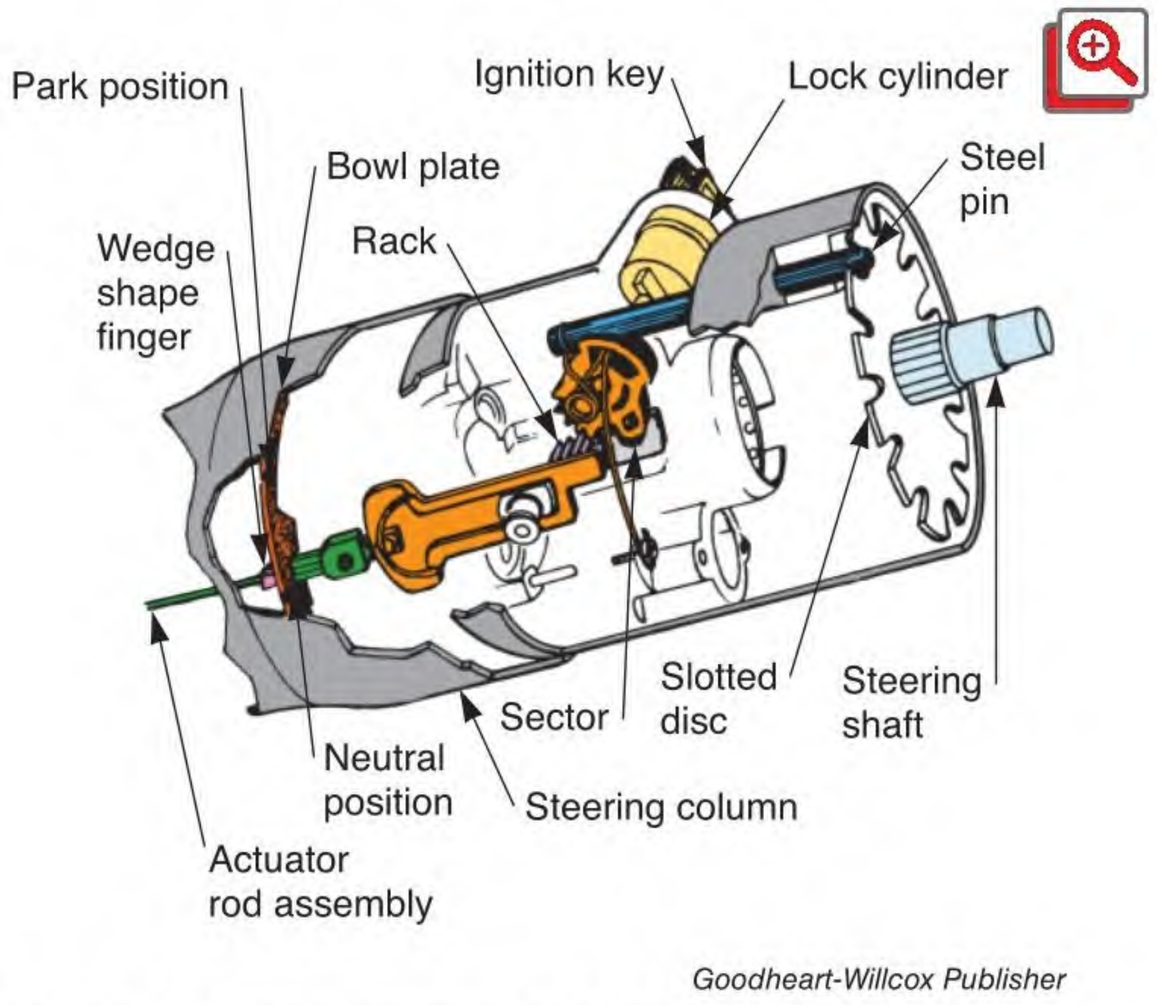
Copyright Goodheart-Willcox Co., Inc.

Steering Column Assembly

The ***steering column assembly*** consists of the steering wheel, steering shaft, column (outer housing), and, sometimes, ignition key mechanism, a flexible coupling, and a universal joint. Look at **Figure 77-2**.

The steering column normally bolts to the underside of the dash. The column sticks through the firewall and fastens to the steering gear assembly.

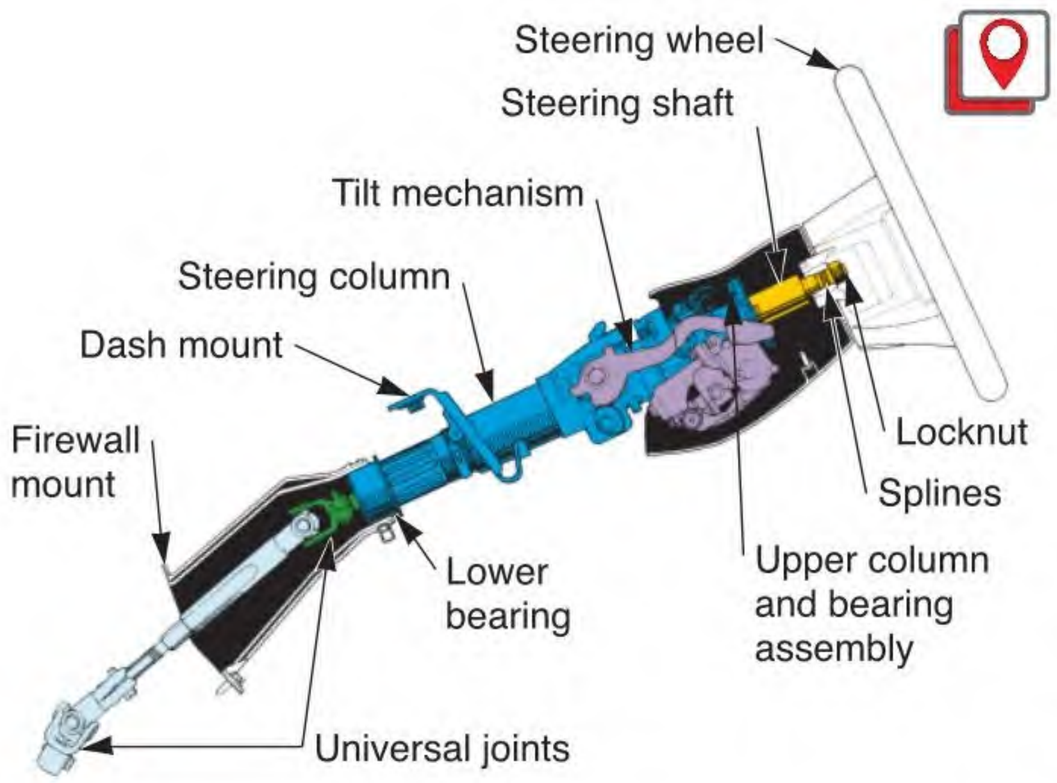
Bearings fit between the steering shaft and the column. They let the shaft rotate freely. The steering wheel is splined to the shaft. A large nut holds the steering wheel on the shaft splines. The driver's-side air bag fastens to the steering wheel.



Ignition Lock and Switch

The ignition lock and switch mechanism are mounted on the steering column in most vehicles. The ***ignition lock mechanism*** is normally on the top, right-hand side of the column. The ***ignition switch*** is usually bolted inside the steering column.

Locking Steering Wheel



To help prevent theft, late-model vehicles have a ***locking steering wheel***. When the ignition key is off, the steering wheel cannot be turned.

Figure 77-3 shows a common method of locking the steering wheel. A rack and a sector are used to slide a steel pin into mesh with a slotted disc that is splined to the steering shaft. This locks the steering shaft to the column, preventing the steering wheel from being turned.

Goodheart-Willcox Publisher

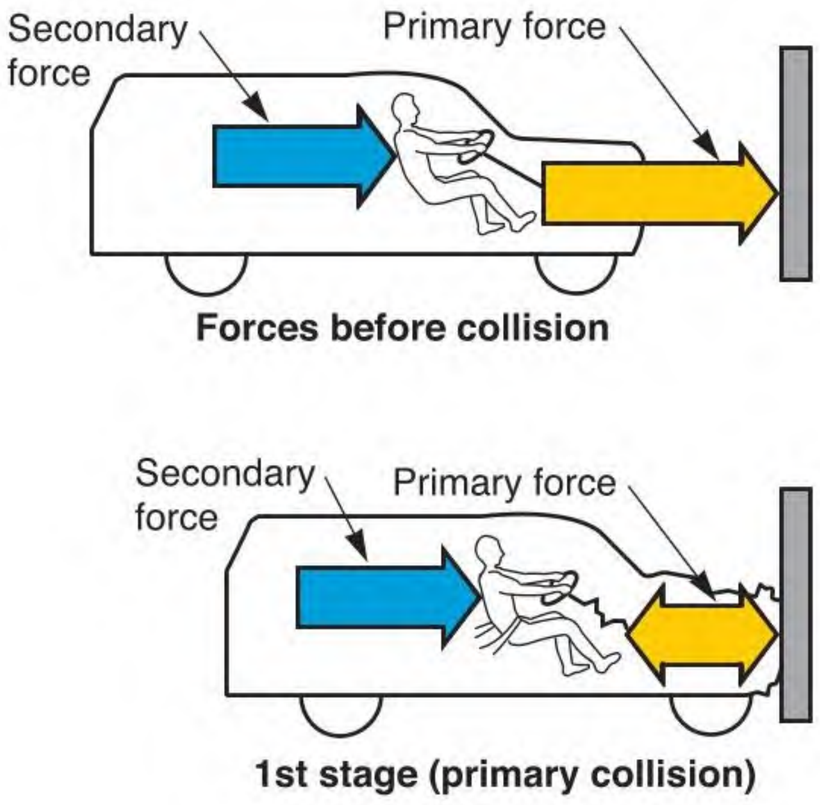
Figure 77-3. Cutaway view shows how a locking steering column functions. The steel pin slides into a slot in the disc to keep the wheel from turning after the key is removed. Also note the small rod that extends down to the ignition switch.

Lexus

Figure 77-2. Note the steering column components. The steering wheel is splined to a shaft that extends through the column and down into the steering gearbox. This is a tilt column, which allows the steering wheel to be moved into different driving positions.

Collapsible Steering Column

Most vehicles use a ***collapsible steering column*** to help prevent driver chest and face injury during an auto accident. The column is designed to crumple or slide together when forced forward during a collision. Look at **Figure 77-4**.



When a vehicle hits a stationary object, the engine and the front body structure can be pushed rearward into the steering column. At the same time, the driver can be thrown forward into the steering wheel. With a rigid steering column, the driver's chest could be injured.

There are several types of collapsible steering columns: steel mesh (crushing) columns, tube-and-ball (sliding) columns, and the shear capsule (break and slide) columns. In all types, the column is made up of two pieces.

Tilt Steering Columns

A ***tilt steering column***, or ***tilt steering wheel***, has a flex joint, or U-joint, that allows the top half of the column and the steering wheel to be positioned at different angles.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

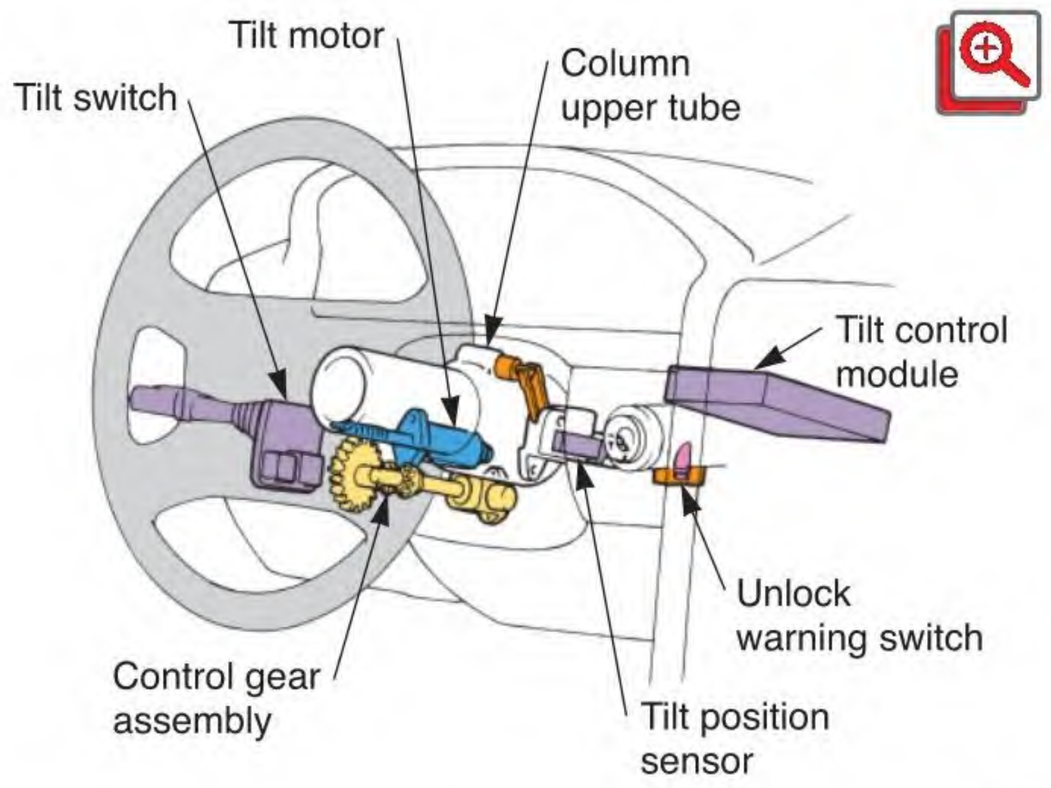


Figure 77-4. A collapsible steering column crushes, protecting the driver.

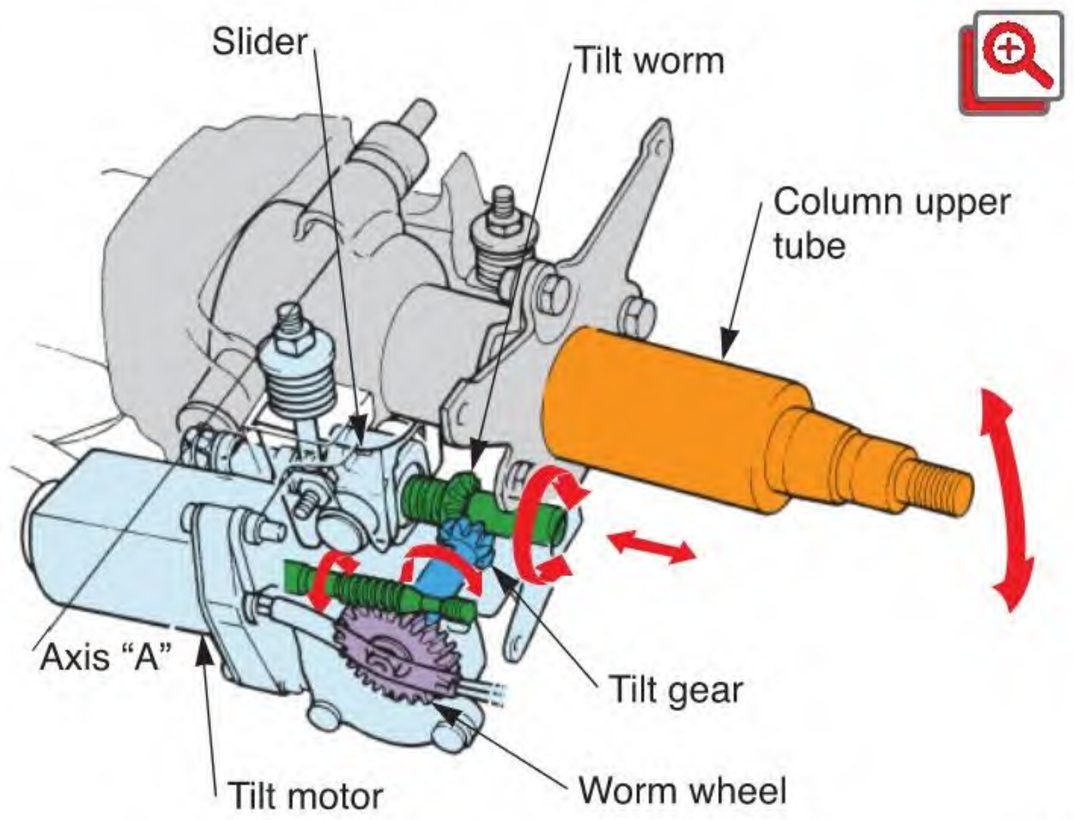
A ***manual tilt column*** uses a lever on the steering column to unlock the flex joint so the wheel can be moved up or down.

A ***power tilt column*** uses a small electric motor, a control switch, and a gear mechanism to change steering wheel angle or height. When the tilt switch is activated, current to the motor spins the small gears to move the steering column's upper tube. Moving the switch the other way reverses current flow through the motor and moves the wheel in the opposite direction.

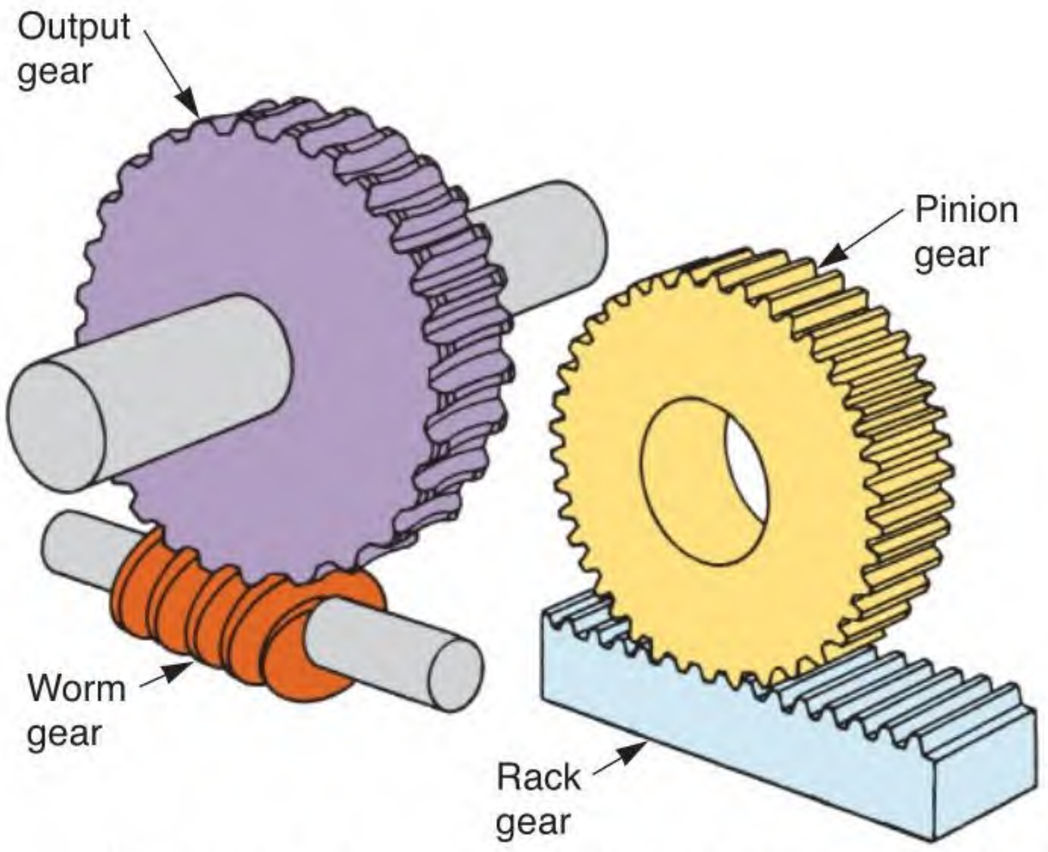


Memory tilt wheels use a tilt control module (computer) to "remember" more than one steering wheel position. A sensor in the steering column provides feedback so the tilt control module knows where the wheel is located. When the driver presses the proper steering wheel position switch, the control module energizes the power tilt motor until the wheel has moved to the driver's preprogrammed position. Refer to **Figure 77-5**.

Many memory tilt wheels will move the steering wheel upward whenever the ignition switch is turned off or on. This gives the driver more room to enter and exit the vehicle. One mechanism for a power tilt steering wheel is detailed in **Figure 77-6**.

Lexus

Figure 77-5. Note the parts of a power tilt steering wheel. This system can be programmed to remember the steering wheel position for more than one driver. The module receives data on steering wheel position from the tilt position sensor. When the driver presses the appropriate tilt switch, the module operates the motor to move the steering wheel to the correct position. In a memory-type system, the module will remember the tilt settings programmed by the driver.



Lexus

Figure 77-6. Note the gear mechanism in this power tilt steering wheel system.

Steering Gear Principles

Mentioned briefly, large pickup trucks sometimes use a worm-type steering gear assembly. Modern passenger cars normally use lighter, less complex rack-and-pinion systems. These two gear principles are illustrated in **Figure 77-7**.

Copyright Goodheart-Willcox Co., Inc.

Deere & Co.

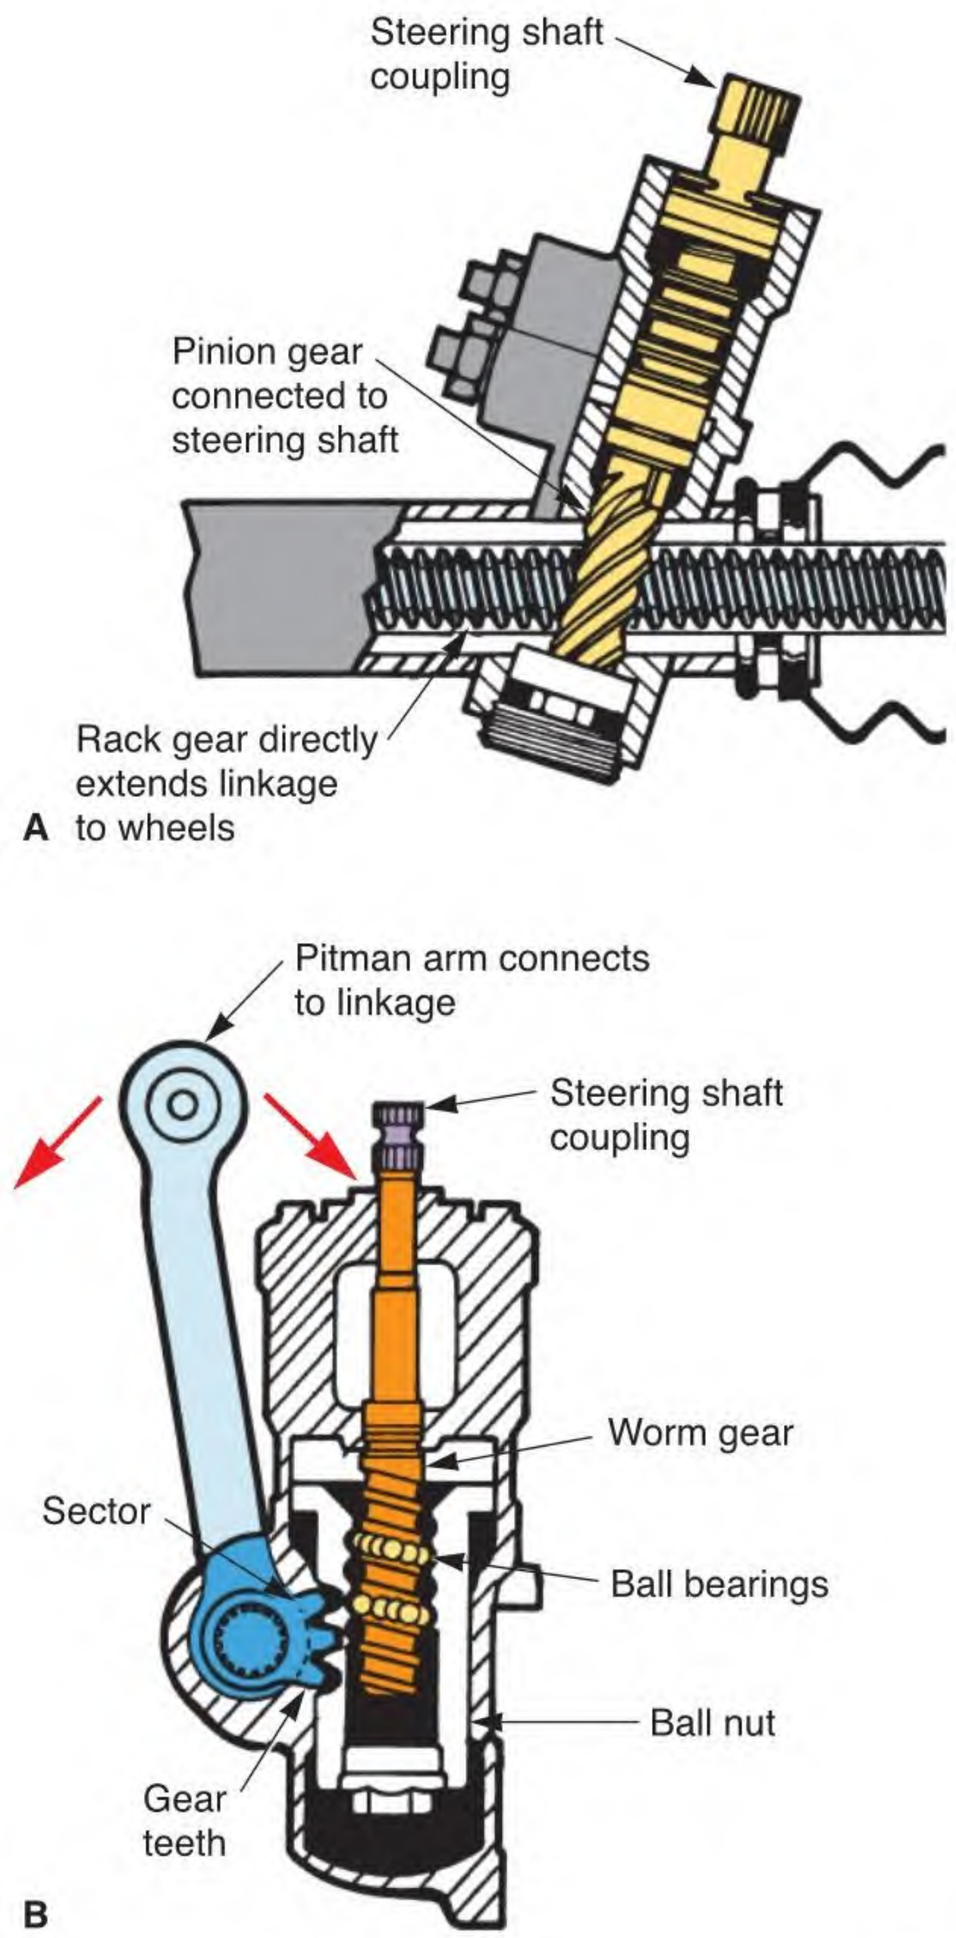
Figure 77-7. Two basic types of gear mechanisms are found in steering gearboxes: worm gears and rack-and-pinion gearset.

Cutaway views of both rack-and-pinion and worm-type (recirculating-ball) steering mechanisms are given in **Figure 77-8**.

Recirculating-Ball Gearbox

The ***recirculating-ball gearbox*** is normally used with a linkage steering system on large trucks. It has small steel balls that circulate between the gear members. See **Figure 77-9**.

A ***worm shaft*** is the input gear connected to the steering column shaft. The balls fit and ride in the grooves in the worm gear.



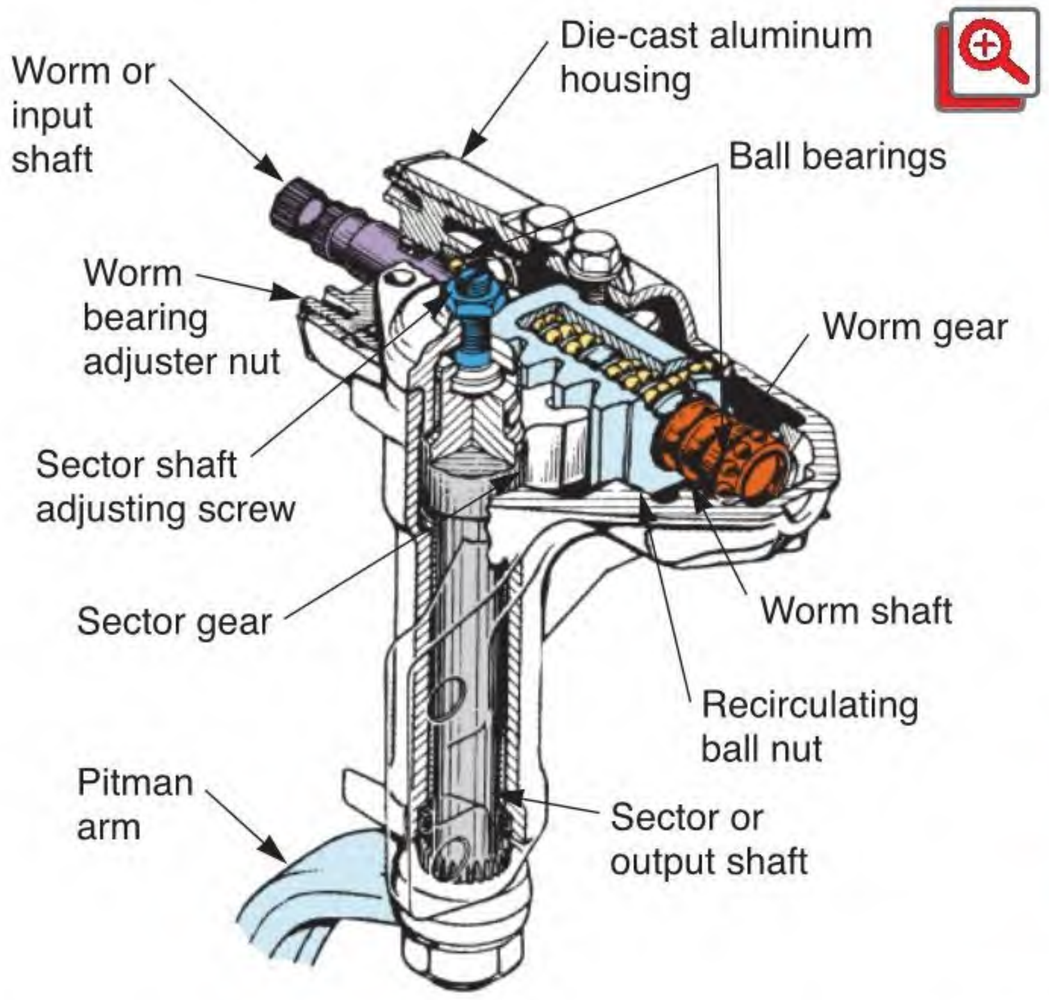
The ***sector shaft*** is the output gear from the steering gearbox. It transfers motion to the steering linkage. A sector gear is machined on the inner end of the sector shaft.

A ***ball nut*** rides on the ball bearings and the worm gear. Grooves are cut in the ball nut to match the shape of the worm gear. Since the ball nut cannot rotate, it slides up and down as the worm gear rotates.

Ball guides route extra ball bearings in and out from between the worm and ball nut.

The worm shaft is mounted in either ball bearings or roller bearings. The sector shaft is also mounted on antifriction bearings.

A bearing ***adjusting nut*** is usually provided to set worm shaft bearing preload. An ***adjusting screw*** is used to set the sector shaft clearance.



Chrysler

Figure 77-8. Another view of two types of steering gears. A—Rack-and-pinion gear. B—Worm steering gear.

The ***gearbox housing*** provides an enclosure for the other components. Seals press into the housing to prevent lubricant leakage at the worm and sector shafts. The shaft bearings also press into the gearbox housing. The housing bolts to the vehicle frame or to a reinforced area on the unitized body.

An ***end cover*** normally bolts on the housing to cover the end of the sector gear. It can be removed for gearbox service.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 77-9. Cutaway view of a recirculating-ball steering gearbox. Study the part relationships. When the steering wheel is turned, the shaft and the worm gear rotate. This causes the balls and the ball nut to walk on the worm. As a result, the ball nut turns the sector gear and shaft.

Gearbox Ratio (Steering Gear Reduction)

Gearbox ratio, also termed ***steering ratio*** or ***steering gear reduction***, is basically a comparison between steering wheel rotation and sector shaft rotation. Steering gearbox ratios range from 15:1 to 24:1. With a 15:1 ratio, the worm shaft turns 15 times to turn the sector shaft once.

A manual gearbox will have a high gearbox ratio to reduce the amount of effort needed to turn the steering wheel. Power steering gearboxes have a lower gearbox ratio so that turning the front wheels requires less steering wheel rotation for faster steering response.

Variable- and Constant-Ratio Gearboxes

A ***variable-ratio gearbox*** changes the internal gear ratio as the front wheels are turned from the center position. Most modern recirculating-ball gearboxes are variable-ratio designs.

Variable-ratio steering is faster when cornering, requiring fewer turns to move the steering wheel from full right to full left. It also provides better control and response when maneuvering.

A ***constant-ratio gearbox*** has the same gear reduction from full left to full right. The sector gear teeth are the same length.

Worm-and-Roller Steering Gearbox

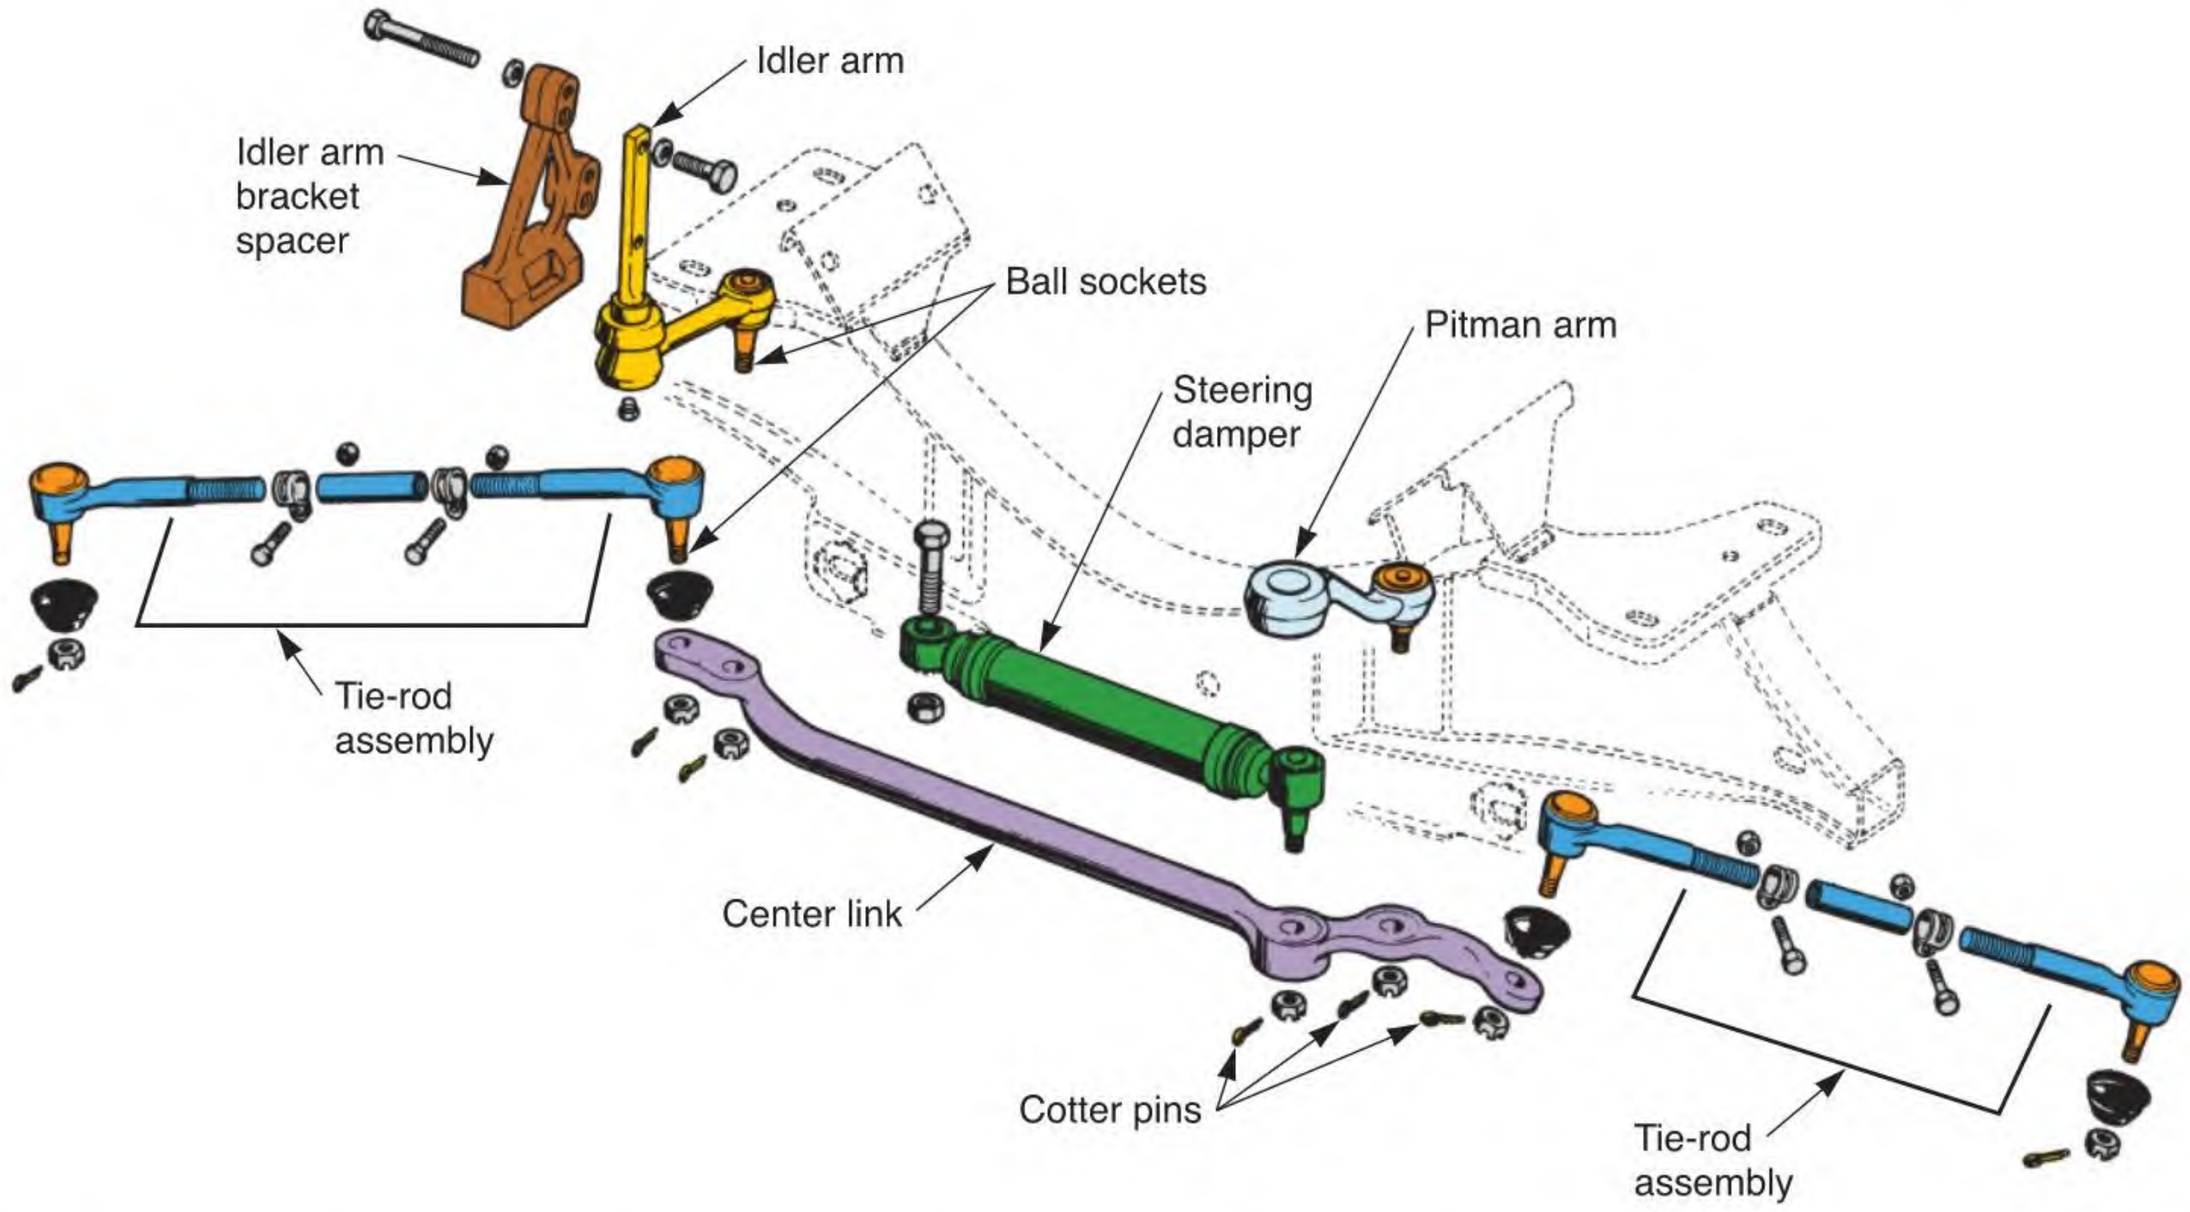
A ***worm-and-roller steering gearbox*** contains a roller that is mounted on the pinion shaft and meshes with the worm gear. The roller replaces the ball bearings and the ball nut used in the recirculating-ball gearbox. The roller imparts a rotary force on the pitman shaft as the worm gear rotates. The worm-and-roller design helps reduce internal friction.

Steering Linkage (Worm-type Gearbox)

The ***steering linkage*** is a series of arms, rods, and ball sockets that connect the worm-type steering gearbox to the steering knuckles. The linkage used with a worm-type gear box is commonly called a ***parallelogram steering linkage***. This type of steering linkage typically includes a pitman arm, a center link, an idler arm, and two tie-rod assemblies. It may also include a steering damper. See **Figure 77-10**.

Pitman Arm

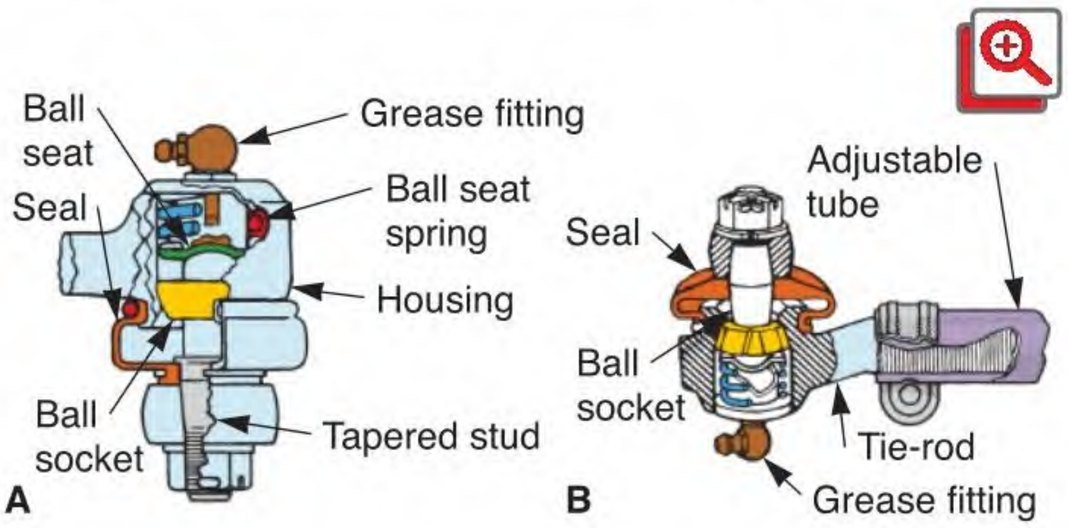
The ***pitman arm*** transfers gearbox motion to the steering linkage. The pitman arm is splined to the gearbox sector (output) shaft. A large nut and lock washer secure the arm to its shaft. The outer end of the pitman arm is normally connected to the linkage through a ball socket, **Figure 77-10**.



Ball sockets provide for motion in all directions between two connected parts. They are needed so the steering linkage is *not* bent and damaged when the wheels turn or move up and down over rough road surfaces. Cutaway views of various ball sockets are given in **Figure 77-11**. Note how a ball stud fits into a socket.

Ball sockets are filled with grease to reduce friction and wear. Some ball sockets are sealed. Others have a grease fitting that allows chassis grease to be injected with a grease gun.

Center Link (Relay Rod)



The ***center link***, also called a ***relay rod***, is simply a steel bar that connects the right and left sides of the steering linkage. It has holes that accept the pitman arm, tie-rods, and idler arm, as shown in **Figure 77-10**.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 77-10. Study the arrangement of this linkage-type steering system. A pitman arm connects to the steering gearbox. The arm swings right or left and moves the other linkage components. This type of steering system is commonly used on large, full-size trucks.

Ford

Figure 77-11. Ball sockets allow linkage components to swivel freely. They are commonly used on the end of the pitman arm, idler arm, and tie-rods. A—Ball socket for an idler arm. B—Ball socket for a tie-rod.

Idler Arm

The ***idler arm*** supports the end of the center link on the passenger side of the vehicle. The idler arm bolts to the vehicle's frame or subframe, **Figure 77-10**.

Steering Damper

The ***steering damper*** is an oil-filled shock absorber found in some parallelogram linkage arrangements. It is attached between the vehicle's frame and the center link to help absorb road shocks before they reach the steering gear. See **Figure 77-10**.

Tie-Rod Assemblies

Two ***tie-rod assemblies*** fasten the center link to the steering knuckles. A tie-rod assembly typically consists of two tie-rods and a toe adjustment sleeve. Ball sockets are normally used on both ends of each tie-rod assembly with linkage steering systems. Look at **Figure 77-10**.

The tie-rod that connects to the center link is called the inner tie-rod. The tie-rod that fastens to the steering knuckle is called the outer tie-rod.

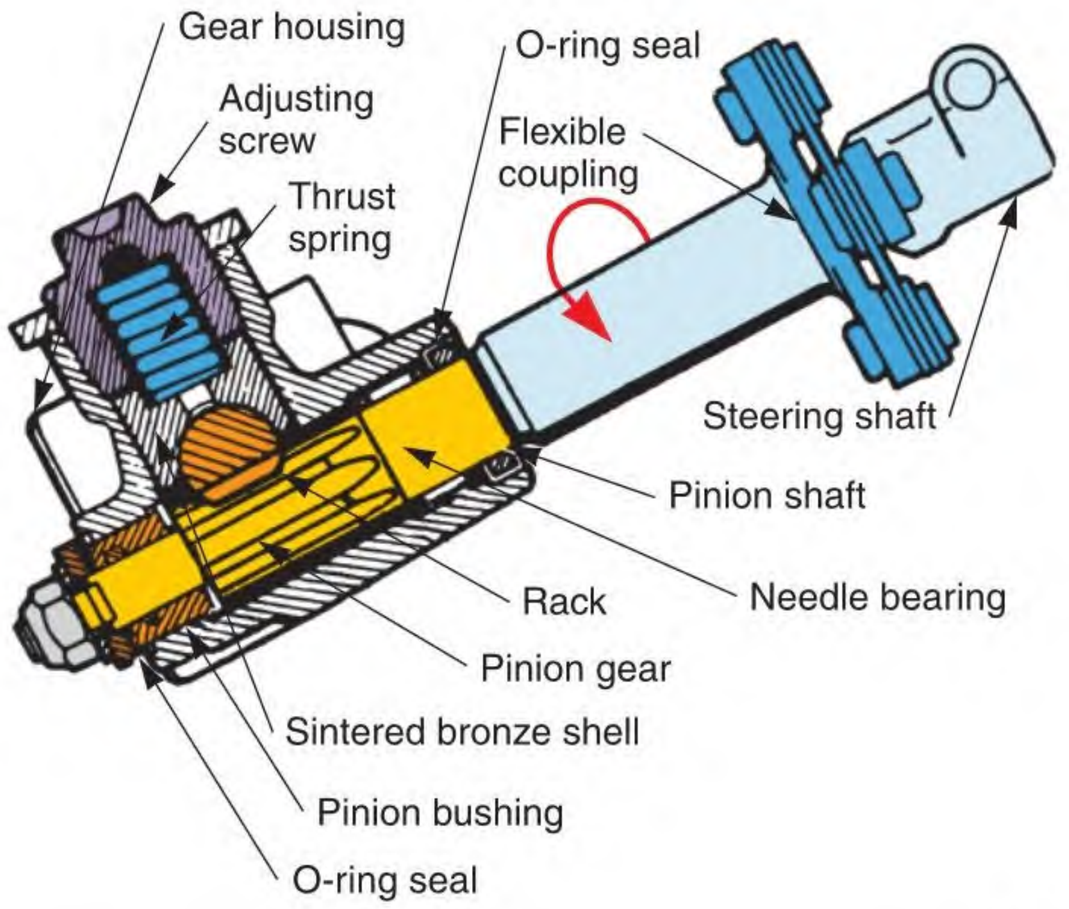
The ***toe adjustment sleeve*** is provided for changing the length of the tie-rod assembly during wheel alignment. The tie-rods and sleeves are threaded so the assembly can be lengthened or shortened to adjust toe-in or toe-out of the front wheels. This is explained fully in a later chapter.

Copyright Goodheart-Willcox Co., Inc.

Manual Rack-and-Pinion Steering

Rack-and-pinion steering is the most popular type of steering system on today's vehicles. For this reason, it is important that you understand its parts and operating principles. **Figure 77-12** shows the external parts of a manual rack-and-pinion steering mechanism. Note that the steering gear is bolted to the frame crossmember.

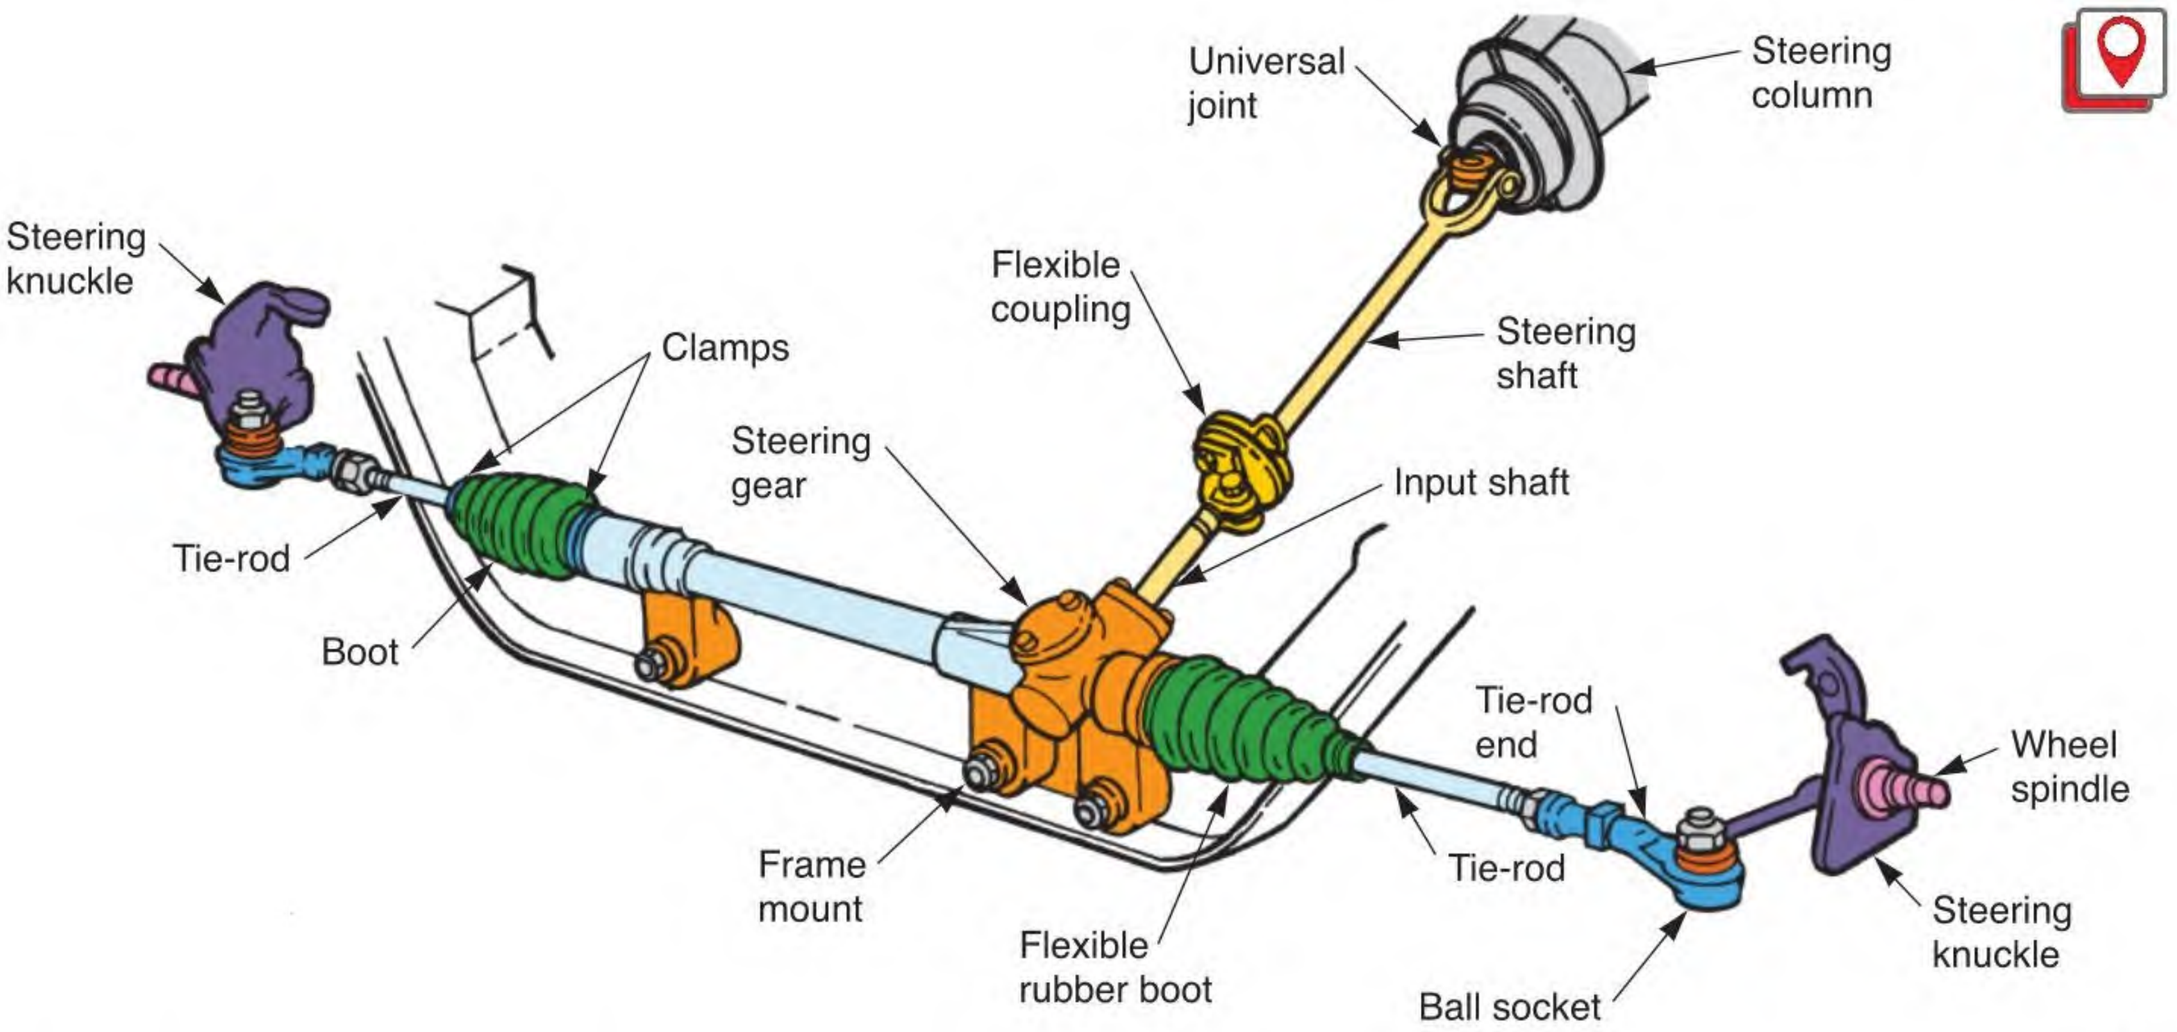
Steering Shaft, Flexible Coupling, and Universal Joint



Many steering systems have a flexible coupling and/or a universal joint in the steering shaft. Look at **Figures 77-12** and **77-13**.

The ***flexible coupling*** helps keep road shock from being transmitted to the steering wheel. It also allows for slight misalignment of the steering shaft and steering gear input shaft (pinion shaft).

A ***universal joint*** allows for a change in the angle between the steering column and steering shaft. One is shown in **Figure 77-12**.



Rack-and-Pinion Steering Gear

A manual ***rack-and-pinion steering gear*** basically consists of a pinion shaft, a rack, a thrust spring, bearings, seals, and a gear housing. The assembly bolts to the vehicle's frame or unibody structure. Large bolts with rubber bushings secure the unit and help absorb road shock. A cutaway view of a rack-and-pinion steering gear is shown in **Figure 77-13**.

Ford

Figure 77-13. Cutaway shows how a pinion shaft gear rotates in its housing. The pinion gear teeth mesh with the rack gear teeth to slide the rack left or right for steering action. The thrust spring holds the rack-and-pinion gears in contact.

Ford

Figure 77-12. Study the components of this manual rack-and-pinion steering system. It uses fewer parts than a linkage system.

Copyright Goodheart-Willcox Co., Inc.

When the steering shaft turns the pinion shaft, the pinion gear acts on the rack gear. The rack then slides sideways inside the gear housing, **Figure 77-14**.

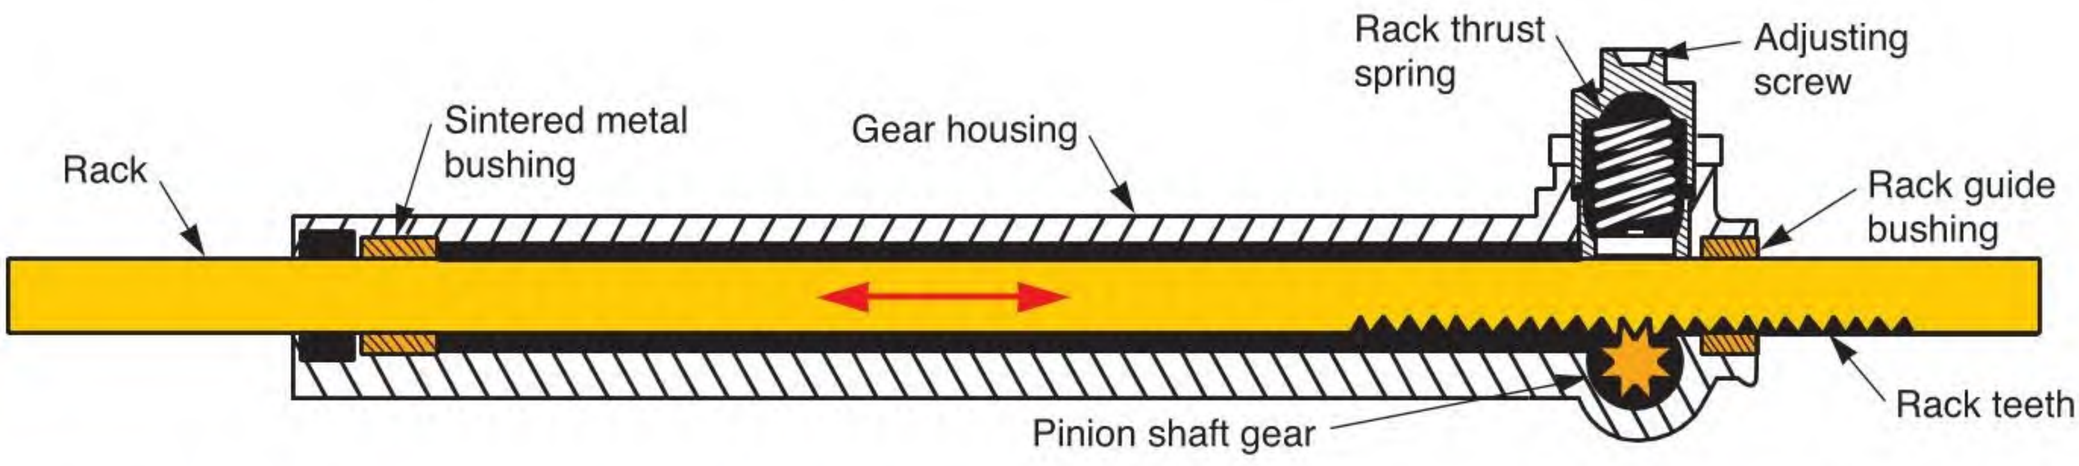
The ***thrust spring*** preloads the rack-and-pinion gear teeth to prevent excessive gear backlash (play). Adjustment screws or shims may be used to set thrust spring tension.

Either bushings or roller bearings may be used on the pinion shaft and the rack. Frequently, the pinion shaft uses roller bearings and the rack uses plain bushings.

Rack-and-Pinion Tie-Rod Assemblies

Tie-rod assemblies for rack-and-pinion steering systems connect the ends of the rack with the steering knuckles. Look at **Figure 77-15**.

Note the unique construction of the tie-rods used in rack-and-pinion steering. A very large ball formed on one end of each inner tie-rod fits into a socket that screws onto the end of the rack. A conventional ball socket is used on one end of each outer tie-rod.



Rubber dust boots fit over the inner ball sockets to keep out road dirt and water, as well as to hold in lubricating grease. Clamps secure each end of the dust boots.

Power Steering Systems

Power steering systems normally use an engine-driven pump and a hydraulic system to assist steering action. They can also use an electric motor in the rack to provide power assist.

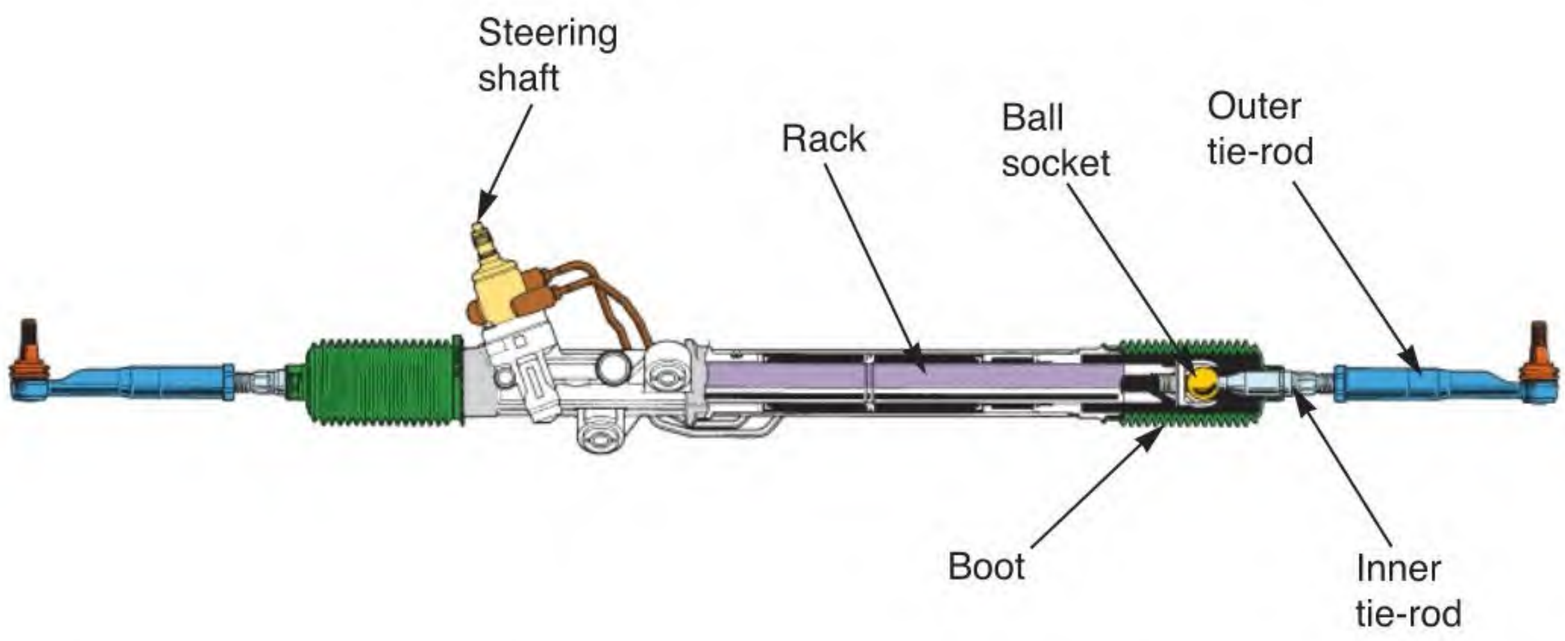


Figure 77-16 illustrates a simplified hydraulic power steering system. Pressure from an oil pump is used to operate a piston-and-cylinder assembly. When the control valve routes oil pressure into one end of the piston, the piston slides in its cylinder. Piston movement can then be used to help move the steering system components and the front wheels of the vehicle.

There are three major types of power steering systems used on modern automobiles: integral-piston linkage systems, external cylinder power steering systems, and power (hydraulic or electric) rack-and-pinion systems. See **Figure 77-17**. The rack-and-pinion system is further divided into the integral and the external power piston systems. The integral rack-and-pinion power steering system is the most common.

Goodheart-Willcox Publisher

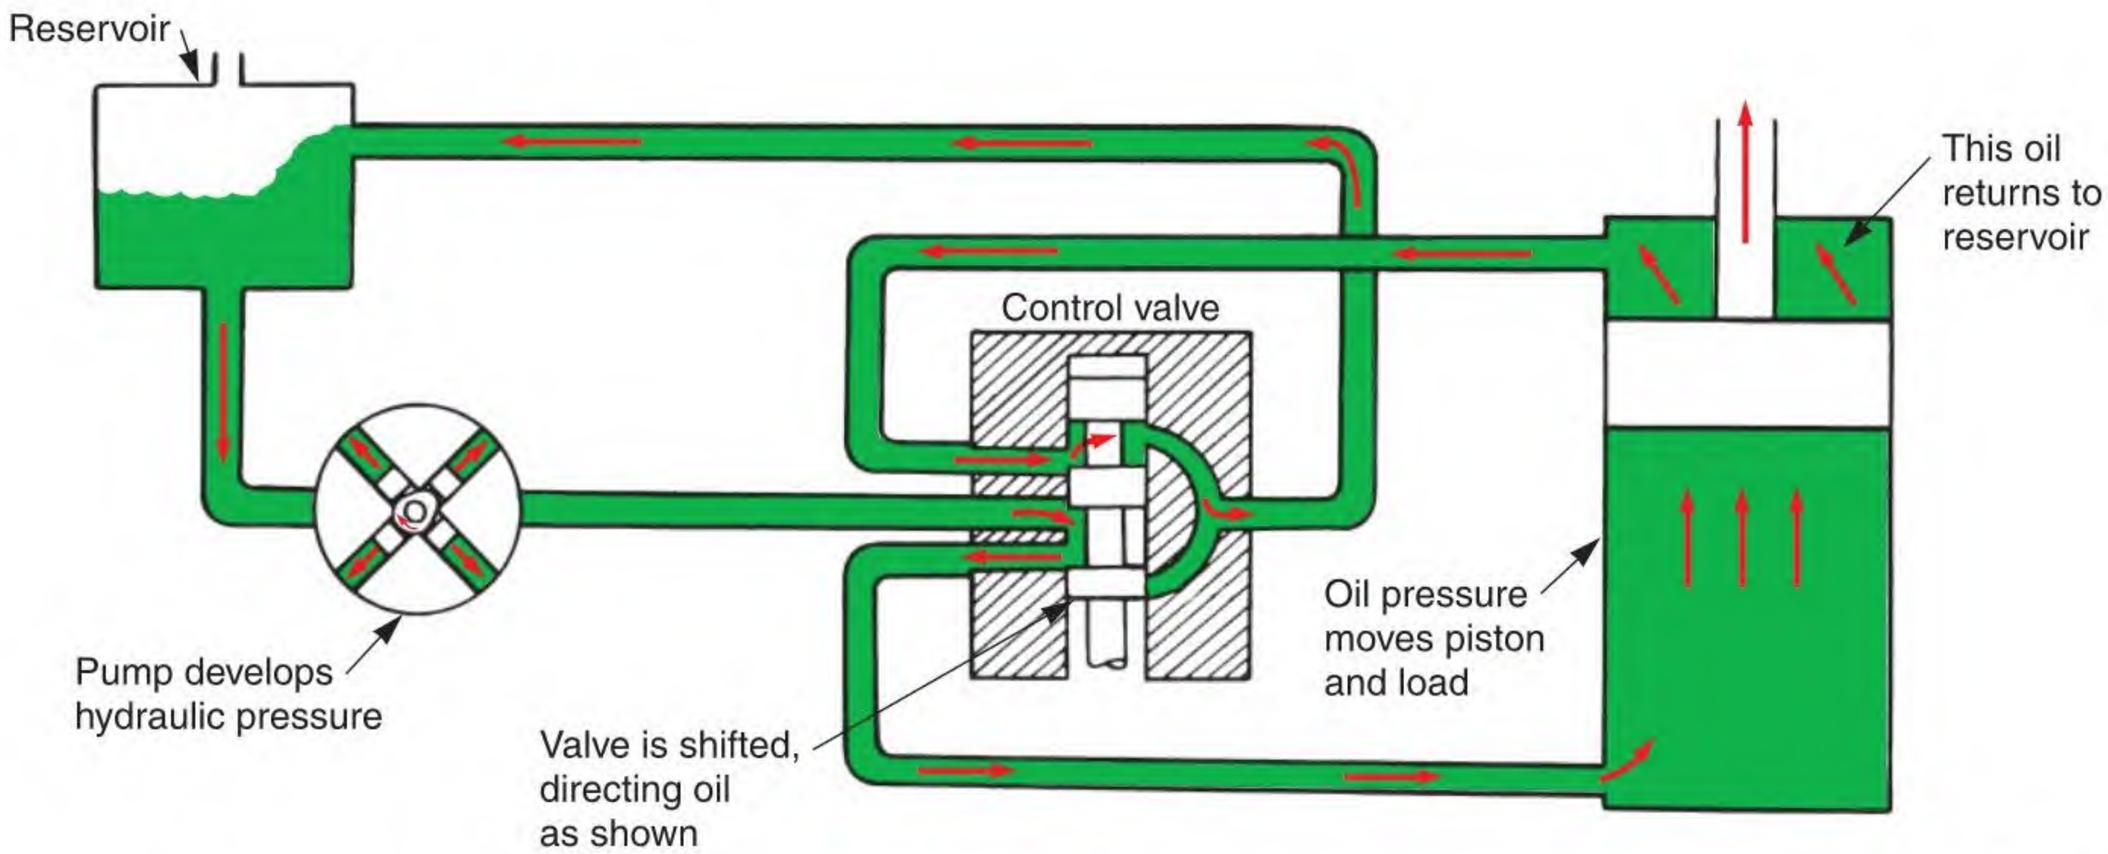

Figure 77-14. The rack slides sideways and pushes or pulls on the tie-rods. This rotates the steering knuckles and the front wheels.

A cutaway view of a modern power rack-and-pinion mechanism is shown in **Figure 77-18**.

Power Steering Pumps

The ***power steering pump*** is engine driven and produces the hydraulic pressure for steering system operation. In most cases, a belt running from the engine crankshaft pulley powers the pump.

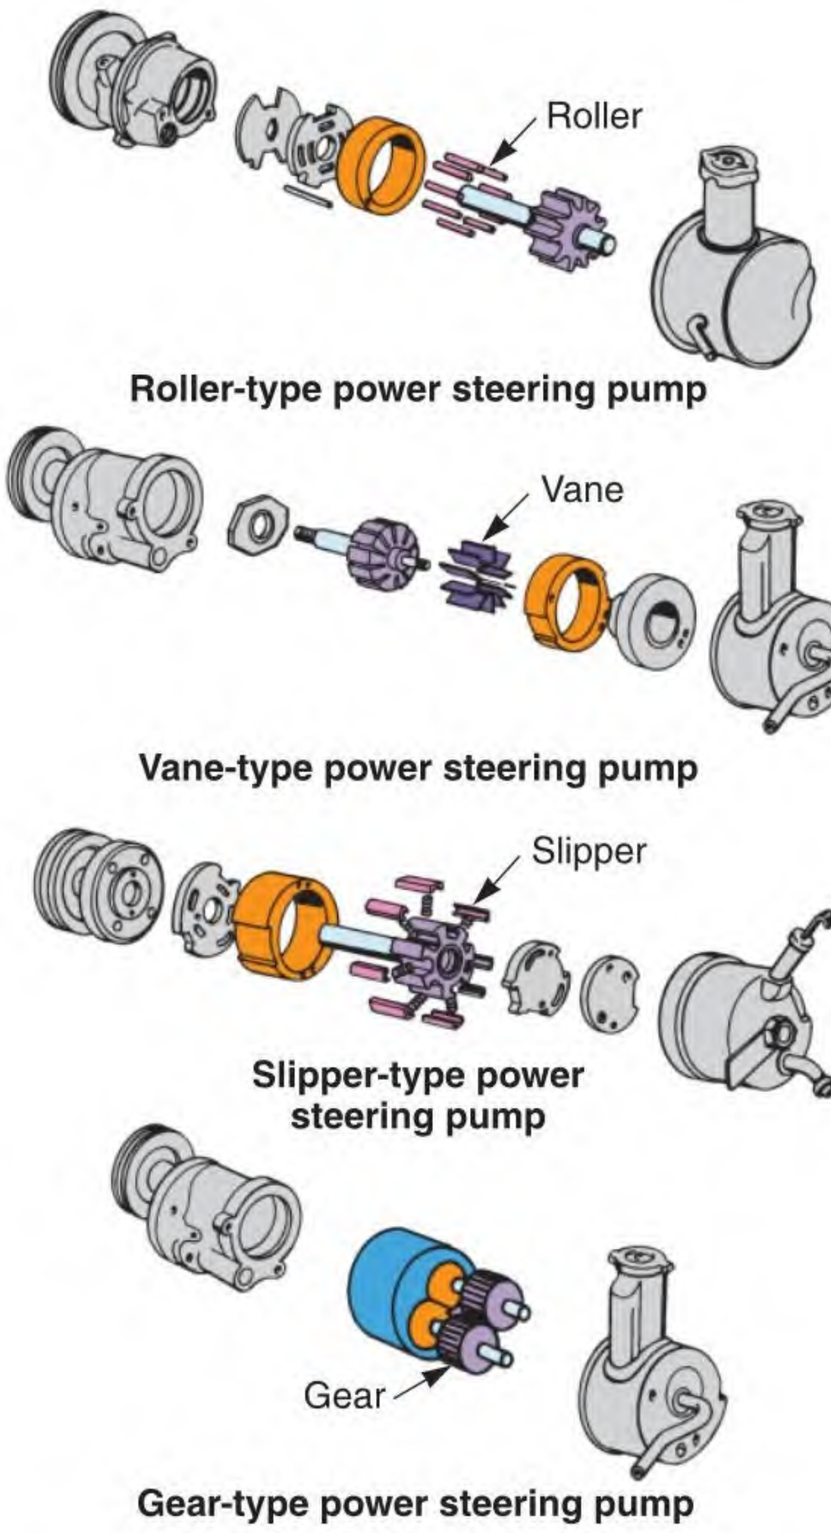

Figure 77-19 shows the four basic types of power steering pumps: roller, vane, slipper, and gear. A cutaway view of a modern power steering pump is shown in **Figure 77-20**.

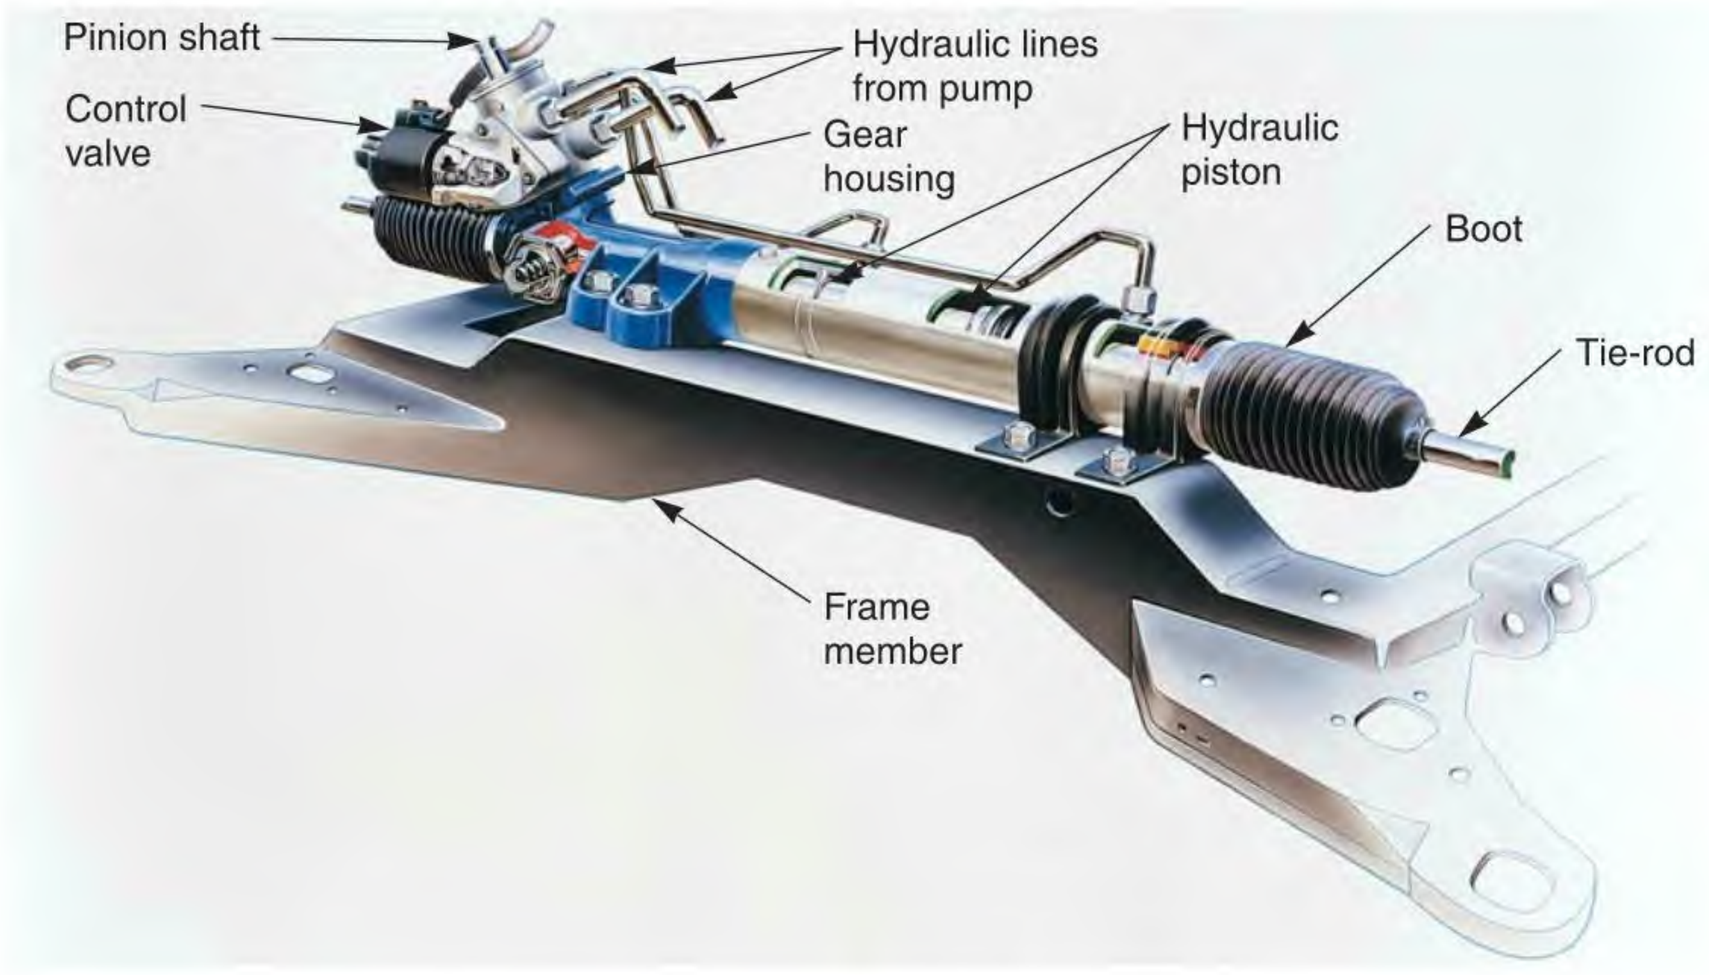
The ***power steering fluid reservoir*** holds an extra supply of power steering oil or fluid. It can be formed as part of the pump body or it can be a separate container. See **Figure 77-21**.

During pump operation, the drive belt turns the pump shaft and pumping elements. Oil is pulled into one side of the pump by vacuum. The oil is then trapped and squeezed into a smaller area inside the pump. This pressurizes the oil at the output, causing it to flow to the rest of the power steering system, **Figure 77-22**.



Pressure-Relief Valve

A ***pressure-relief valve*** is used in a power steering system to control maximum oil pressure. It prevents system damage by limiting pressure when needed. Look at **Figure 77-23**.

Ford

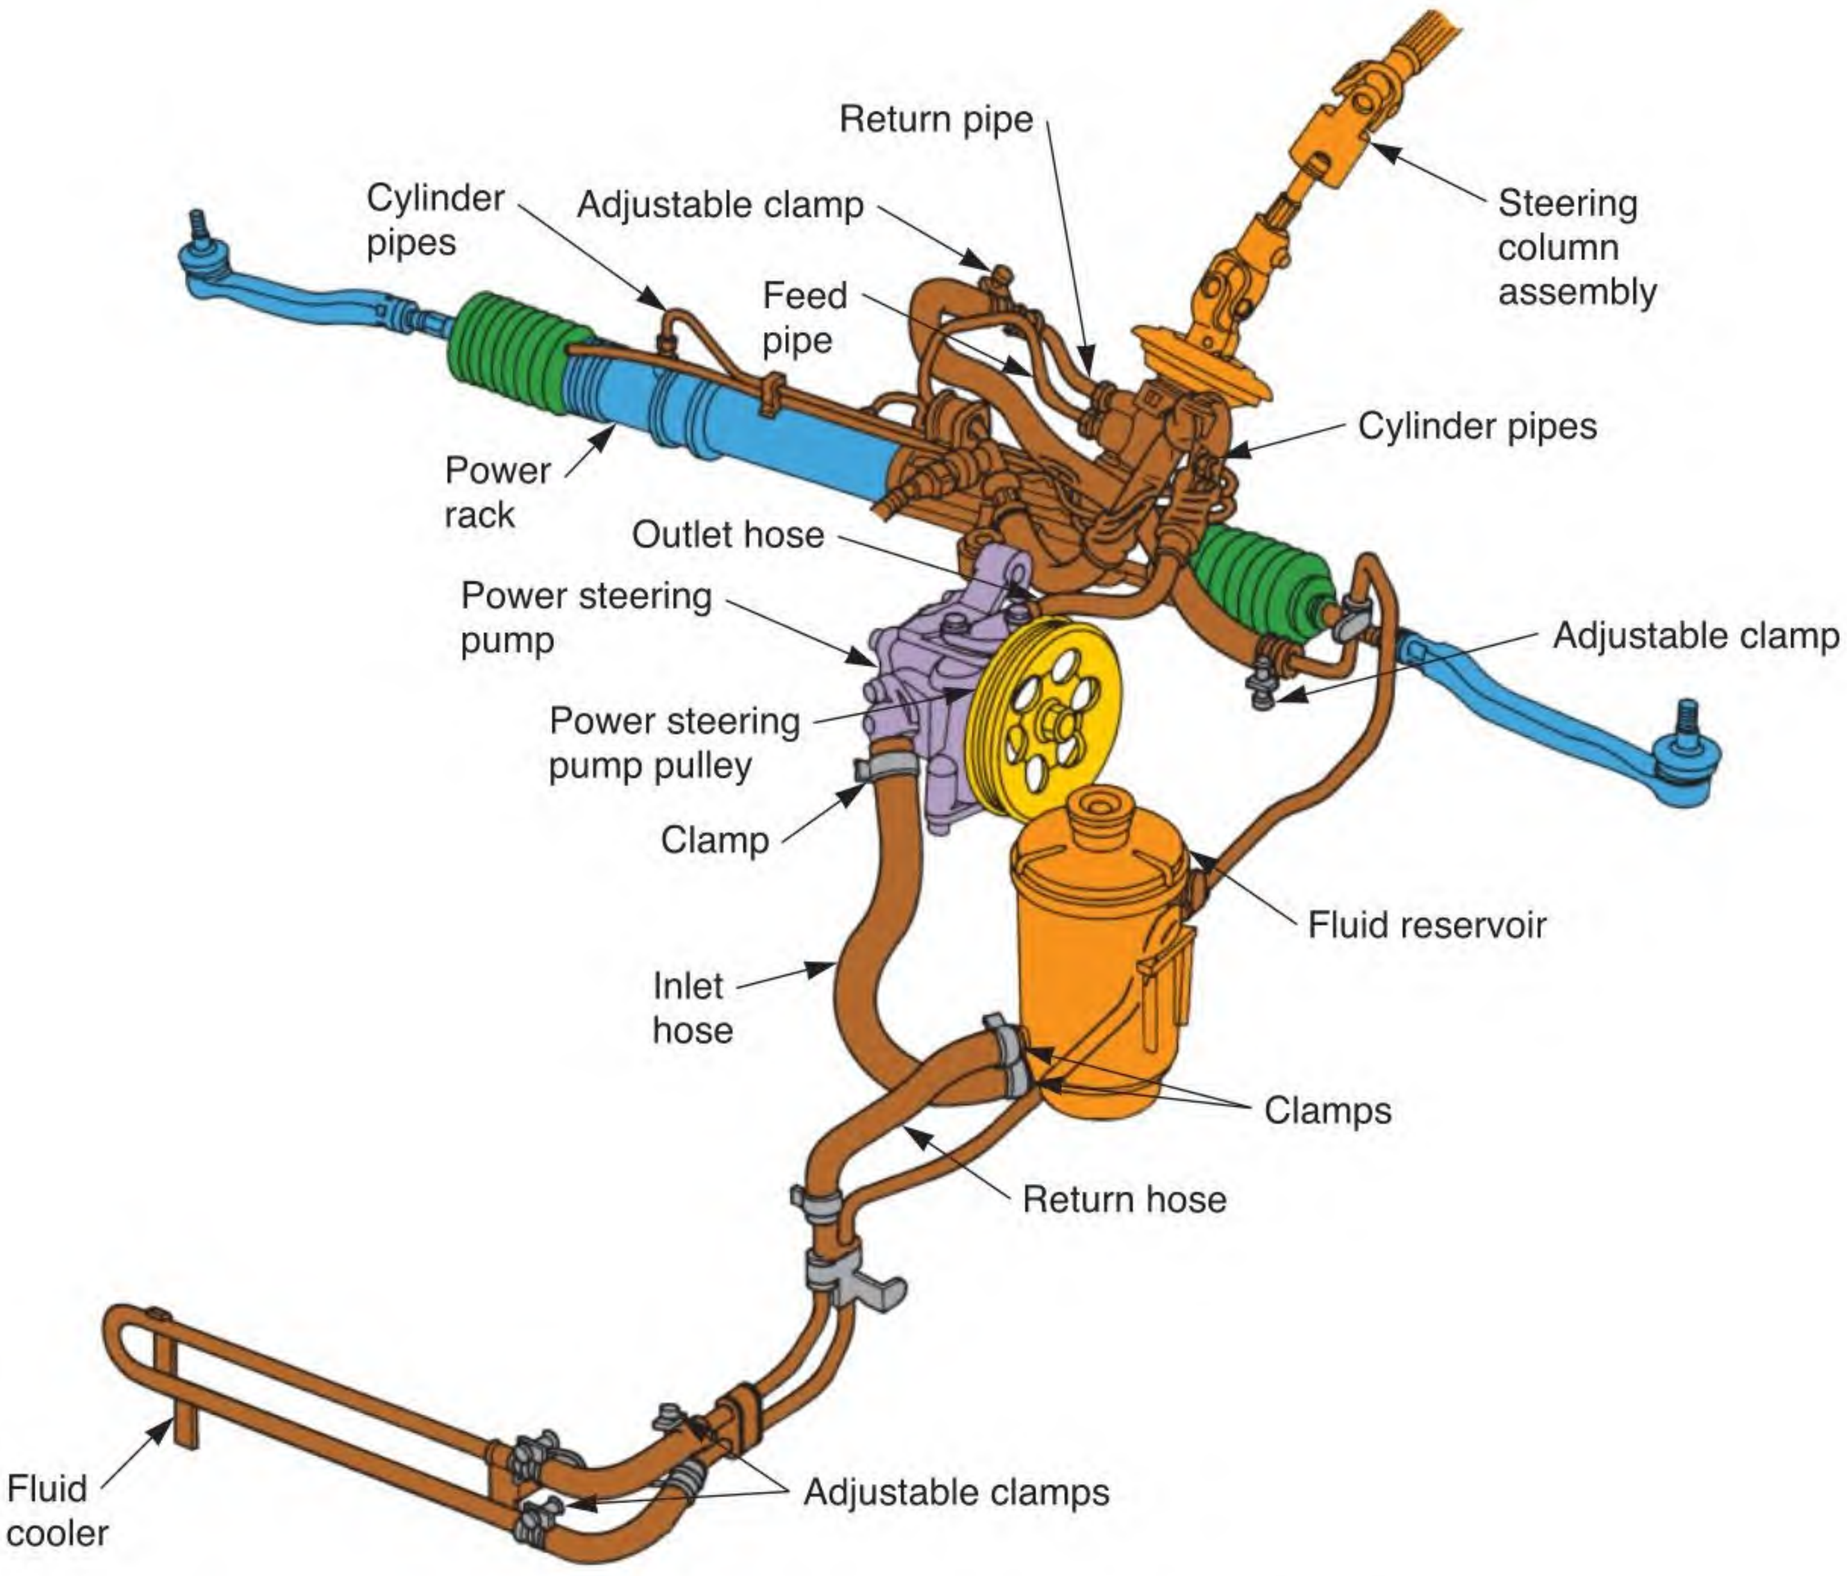

Figure 77-20. Rotation of the input shaft turns the rotor and slippers. Power steering fluid is forced out under pressure.

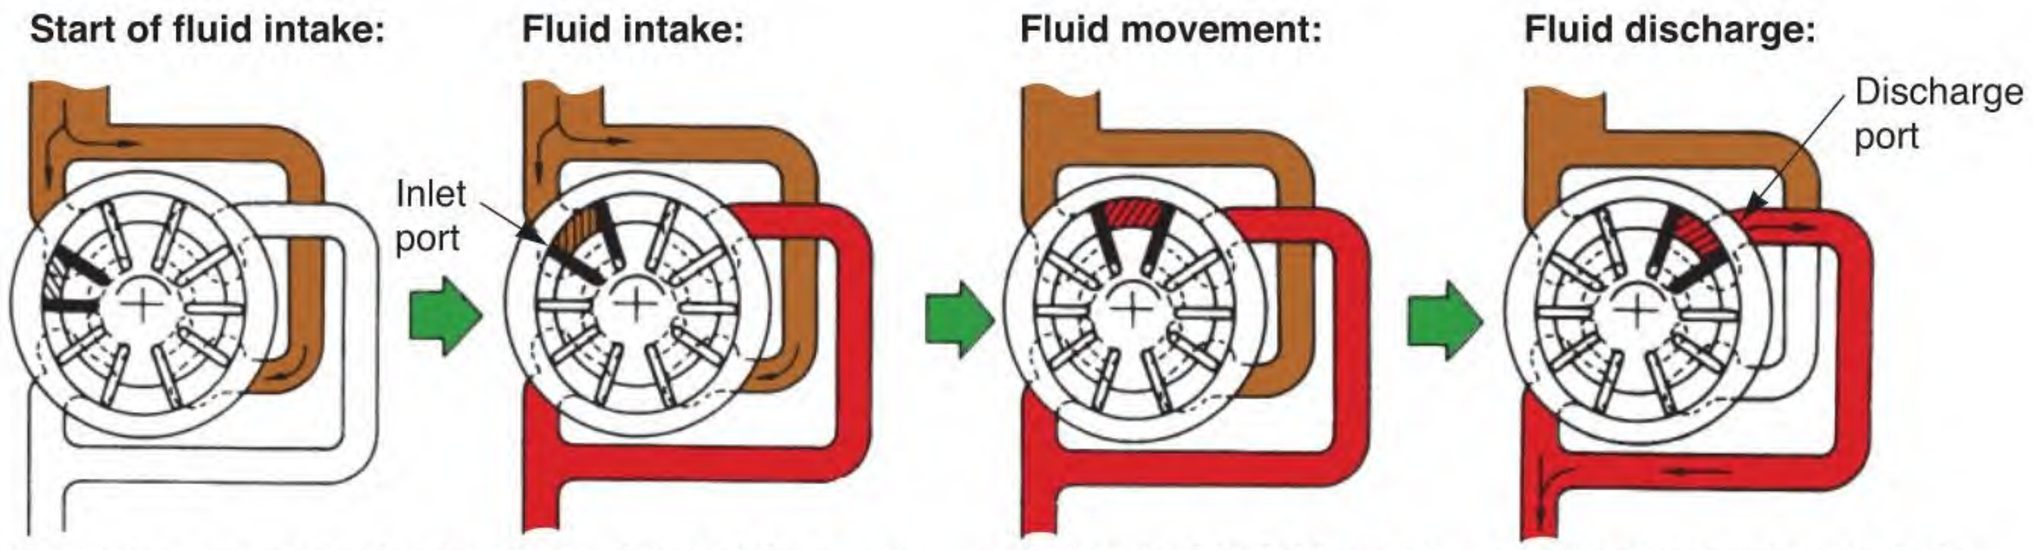
Power Steering Hoses

Power steering hoses are high-pressure, hydraulic, synthetic rubber hoses that connect the power steering pump and the integral gearbox or the power cylinder. One line serves as the pressure feed line. The other acts as a return line to the reservoir. Metal lines are also used to carry fluid between parts where vibration or part movement is not a problem.

Linkage-Type Power Steering Systems



As mentioned, a heavy-duty, linkage-type power steering system is still used on full-size trucks. This makes it important for you to have a basic understanding of these systems.

Honda

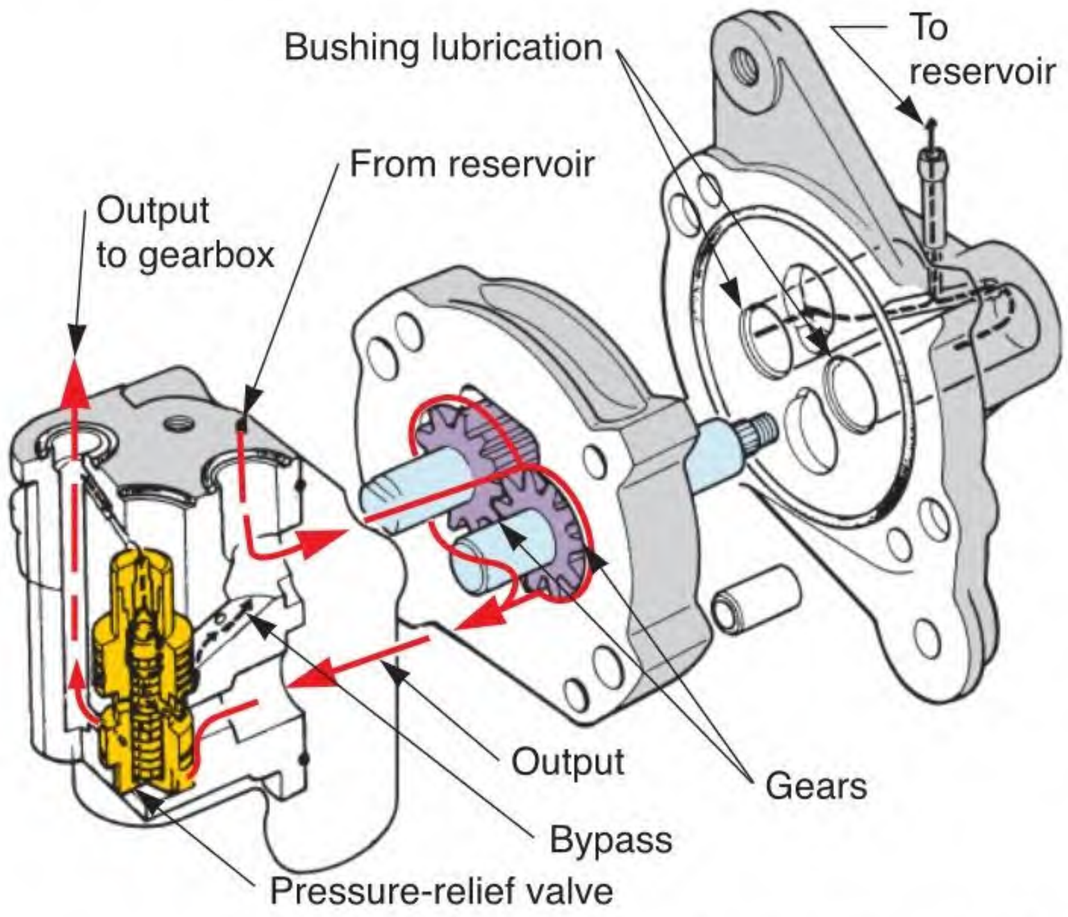


Figure 77-21. The power steering pump generally bolts to the front of the engine. The belt spins the pump. Power steering lines connect the parts of the system. Note the remote reservoir and the oil cooler.

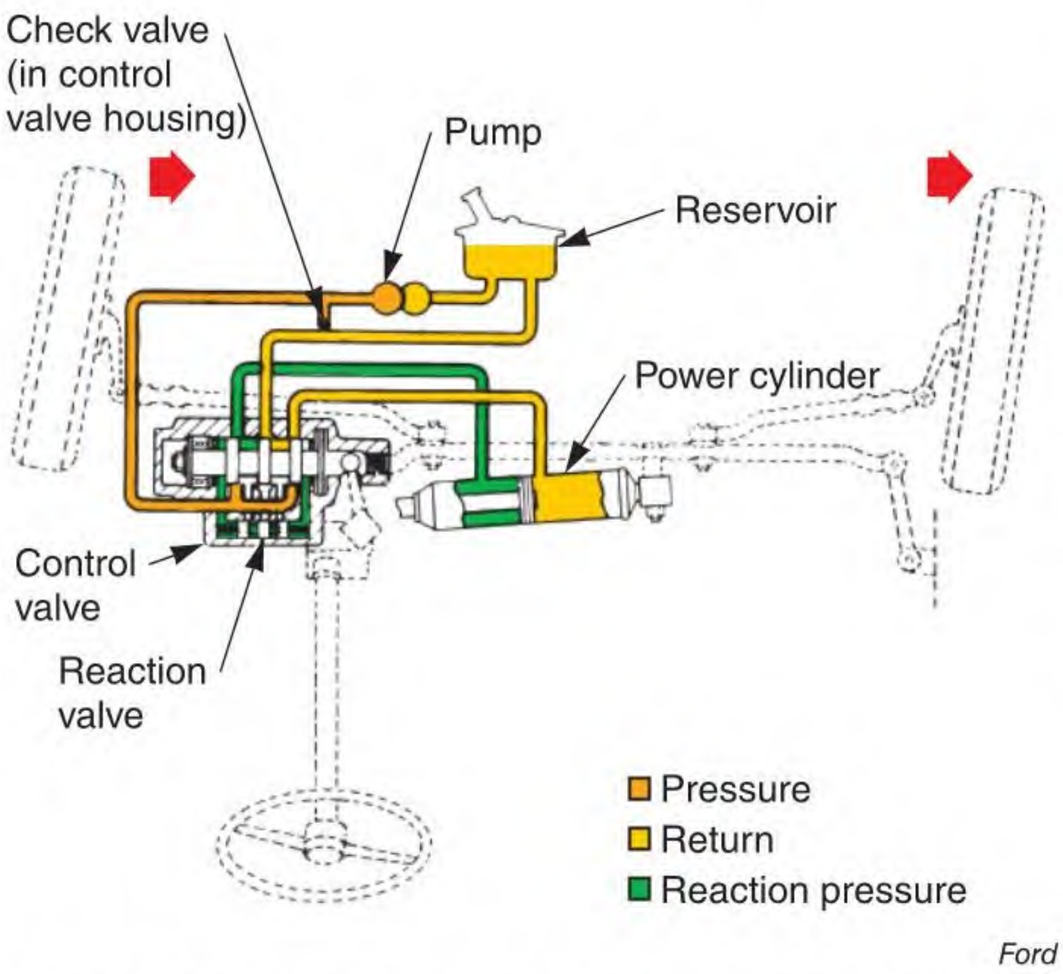
Goodheart-Willcox Publisher

Figure 77-23. Note the construction of this gear-type power steering pump. A pressure-relief valve is built into the body of the pump. The relief valve is designed to open when pressure becomes too high, such as when the steering wheel is turned to the full-right or full-left position.

An ***integral-piston power steering system*** has the hydraulic piston mounted inside the steering gearbox housing. Basically, it consists of a power steering pump, hydraulic lines, and an integral power-assist gearbox.

The ***integral power steering gearbox*** contains a conventional worm-and-sector gear, a hydraulic piston, and a flow-direction valve. One type of integral power steering gearbox uses a ***spool valve***. Another popular type is equipped with a rotary valve.

A spool valve–type power steering gearbox uses a small spool valve to control the pressure entering the power assist chambers.



When the steering wheel is turned to the right, the pivot lever moves the spool valve so that pressure enters the right-turn chamber. This forces the power piston to the left and helps turn the sector shaft for a right turn. Pressure enters the opposite chamber when the steering wheel is turned to the left.

A rotary valve–type power steering gearbox has a small torsion bar to detect steering wheel turning direction and turning effort. When the steering wheel is turned, the torsion bar twists and turns the rotary valve. The ***rotary valve*** then directs hydraulic pressure to the correct side of the power piston. Rotary valve action will be covered later, when discussing power rack-and-pinion steering.

In an ***external cylinder power steering system***, the power cylinder is commonly bolted to the frame and center link. The control valve may be located in the gearbox or on the steering linkage. This is shown in **Figure 77-24**.

External power steering cylinders can be found on older passenger cars and large industrial equipment. This design has been phased out for more compact arrangements.

Copyright Goodheart-Willcox Co., Inc.

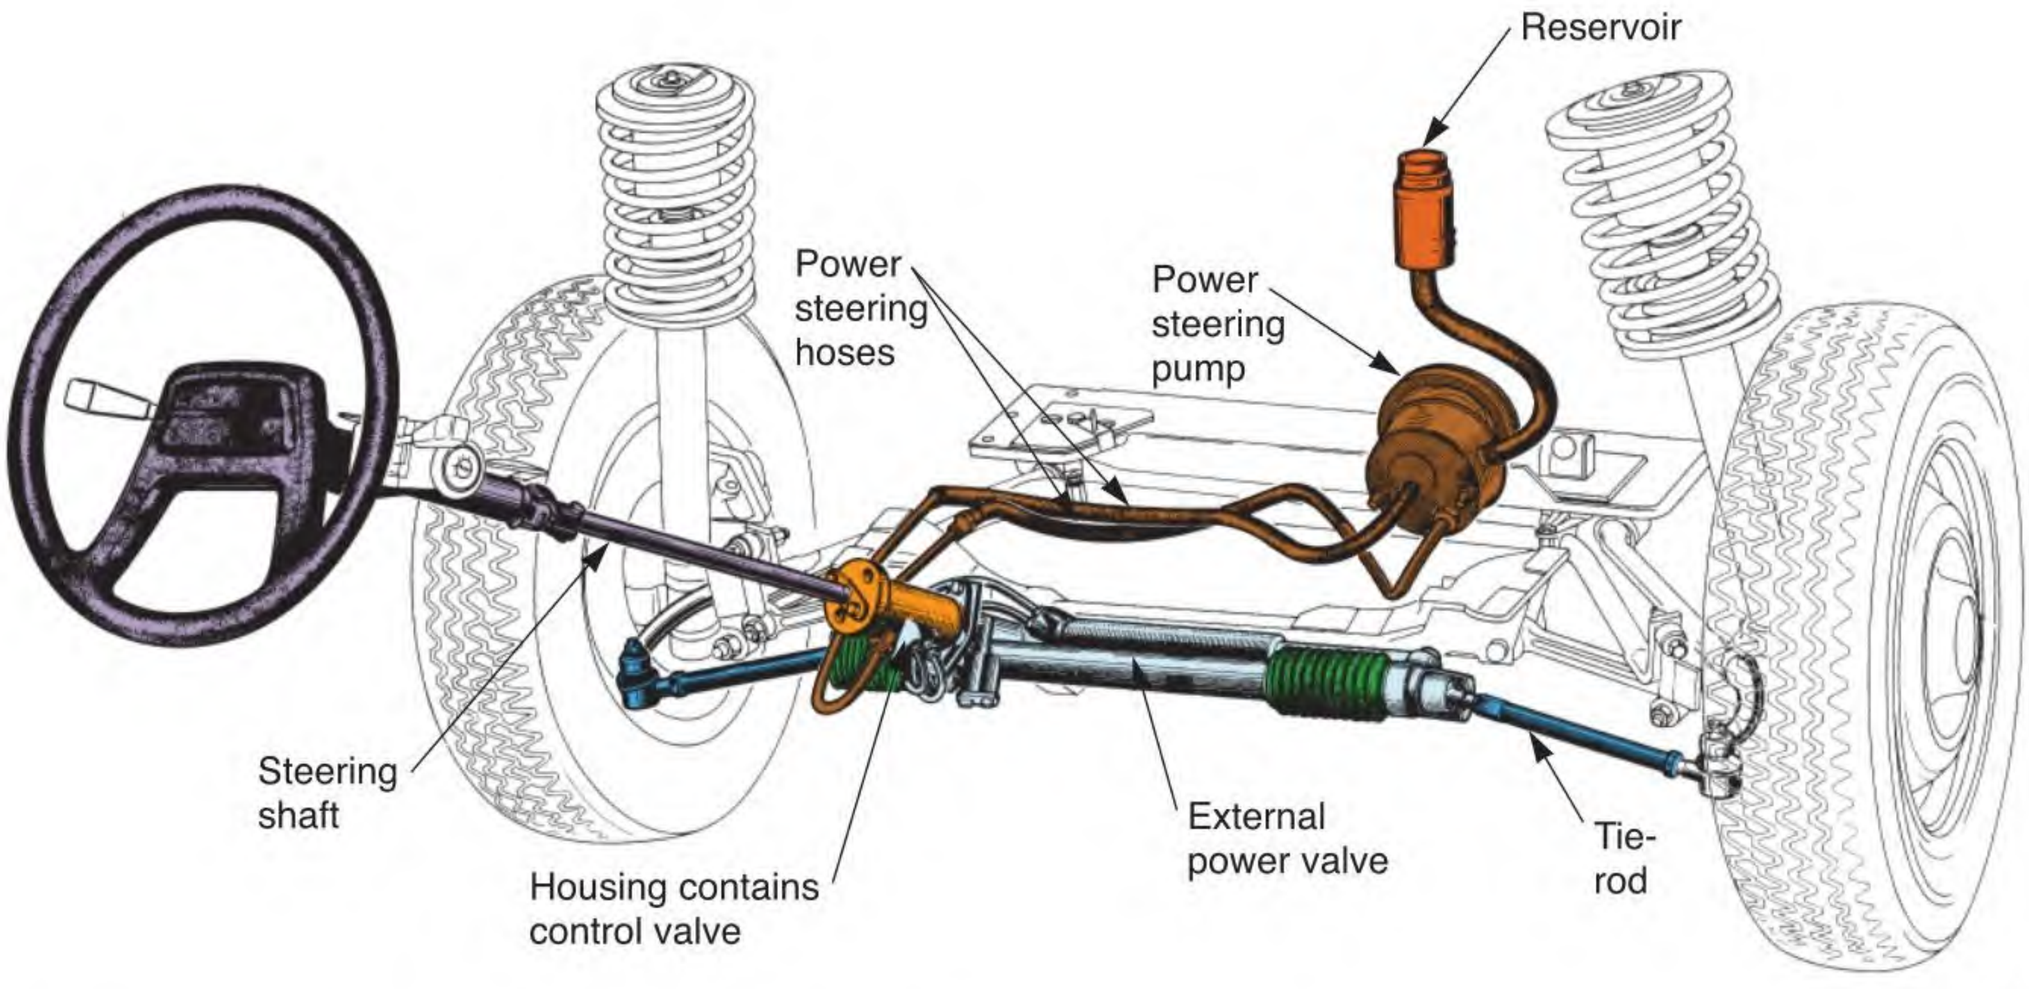
Ford

Figure 77-24. Power steering system using a power cylinder mounted on the steering linkage. Note the system pressures.

Power Rack-and-Pinion Steering

Power rack-and-pinion steering uses hydraulic pump pressure to assist the driver in moving the rack and the front wheels. **Figure 77-25** shows this type of system.

The power steering pump is normally mounted on the front of the engine. A drive belt powers the pump. Power steering hoses and metal lines connect the pump with the rack-and-pinion gear assembly.

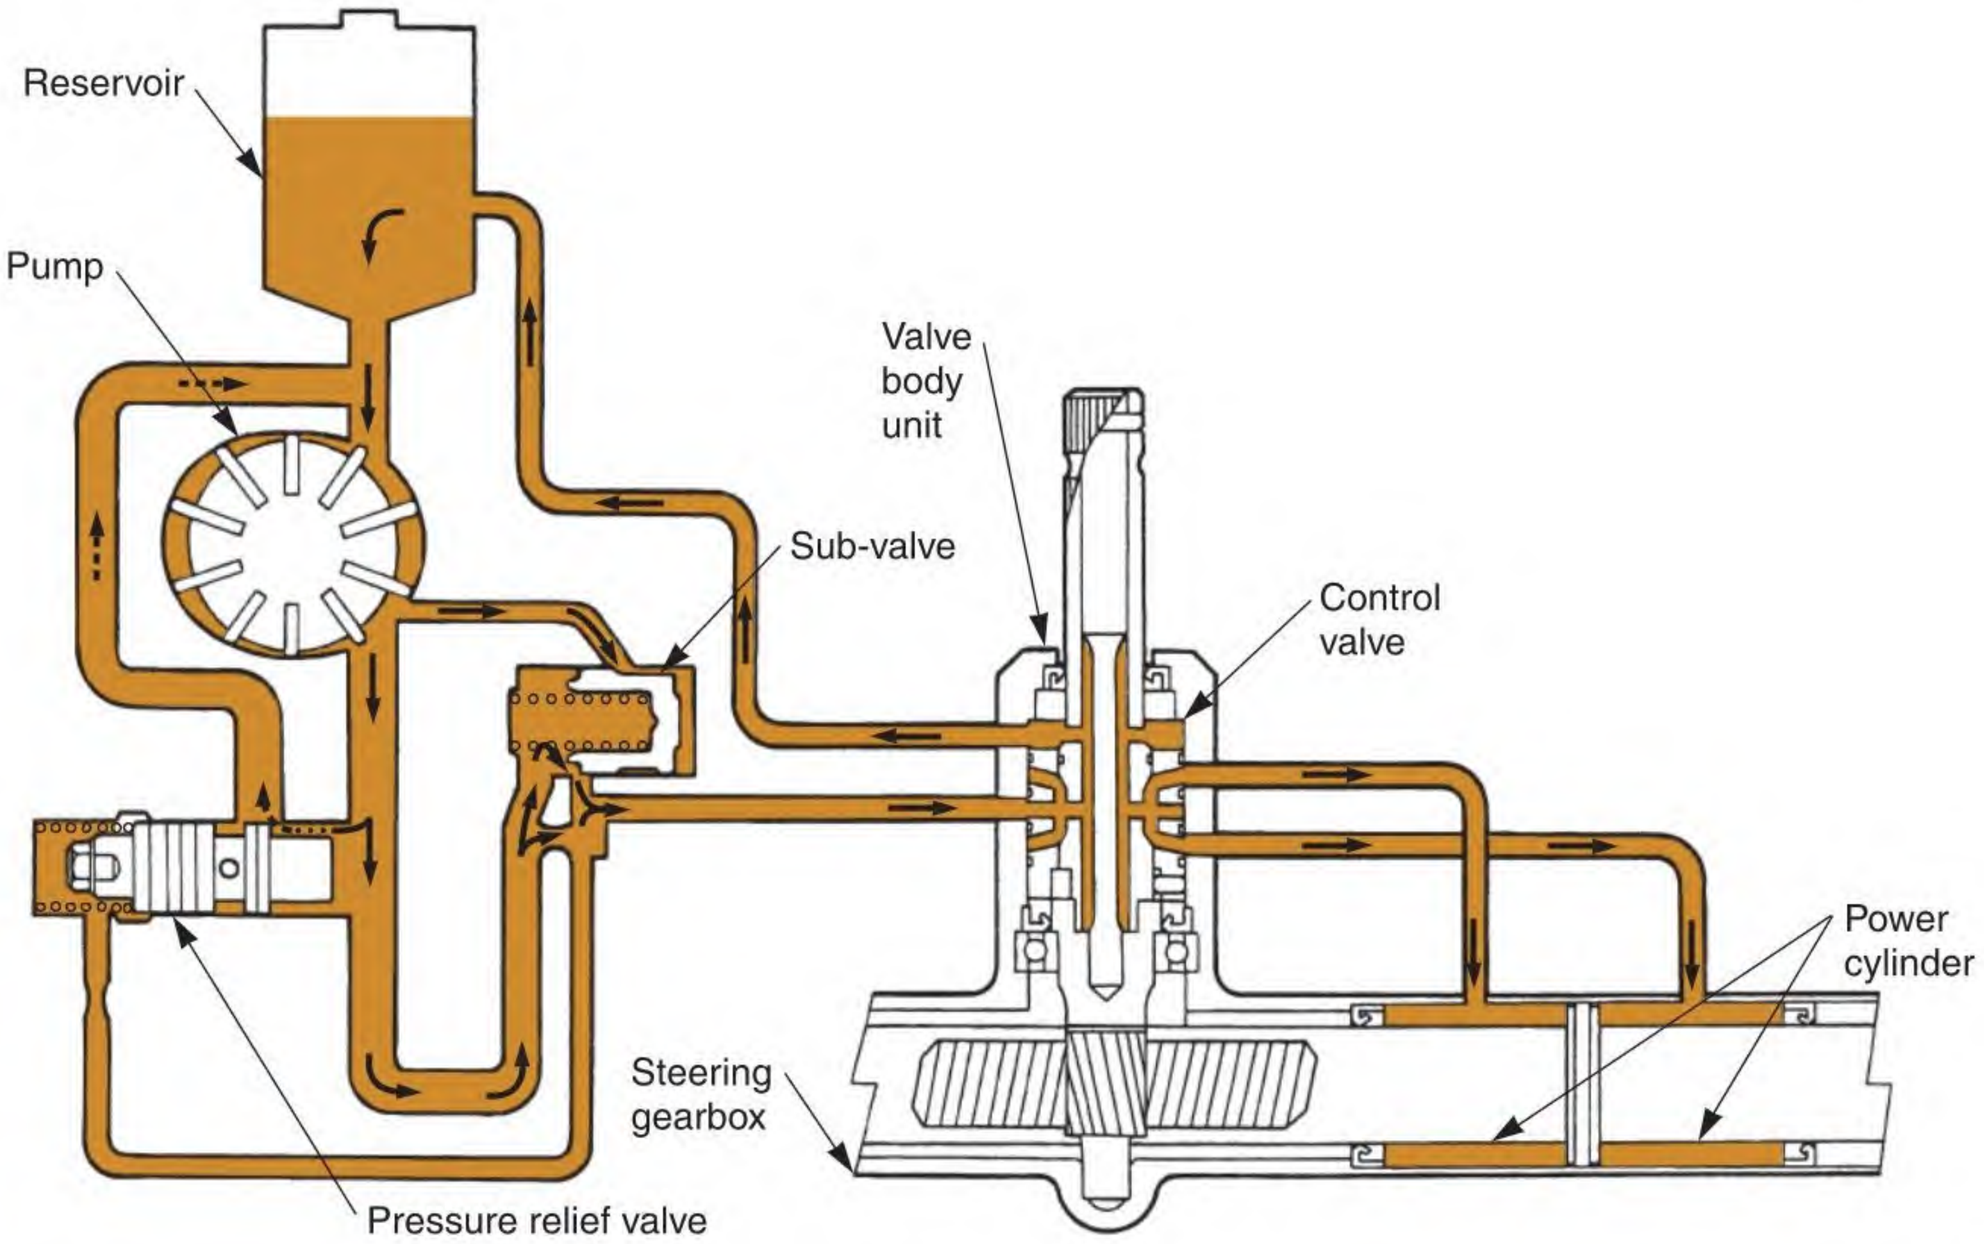


A power rack-and-pinion assembly basically consists of the following:

- ***Power cylinder***—The power cylinder is a hydraulic cylinder machined inside the rack or gear housing.
- ***Power piston***—The power piston is a hydraulic, double-acting piston formed on the rack shaft.
- ***Hydraulic lines***—The hydraulic lines are steel tubing connecting the control valve and the power cylinder.
- ***Control valve***—The control valve is either a rotary valve or a spool valve that regulates pressure entry into each end of the power cylinder.

The other parts of the assembly are similar to those that are found on a manual rack-and-pinion assembly. As shown in **Figure 77-26**, routing oil pressure into either end of the power cylinder causes piston operation and steering assist. The hydraulic assist reduces the amount of arm strength required to turn the steering wheel.

Power Cylinder and Piston



A power cylinder for a rack-and-pinion steering system is a precisely machined tube designed to

Peugeot

Figure 77-25. External view of a power rack-and-pinion setup.

Honda

Figure 77-26. The power cylinder is formed around the rack. Pressure acts on the rack piston to help slide the rack in its housing. Although the valve shown here is in the neutral position, the control valve can direct pressure to either side of the power piston.

accept the power piston. Provisions are made for the hydraulic lines. The cylinder housing bolts to the vehicle frame member, just like a manual unit.

The power piston is formed by attaching a hydraulic piston to the center of the rack. A rubber seal fits around a groove in the piston to prevent oil pressure leakage. Seals are also used on each end of the piston to keep fluid from leaking into the boots. This is shown in **Figure 77-27**.

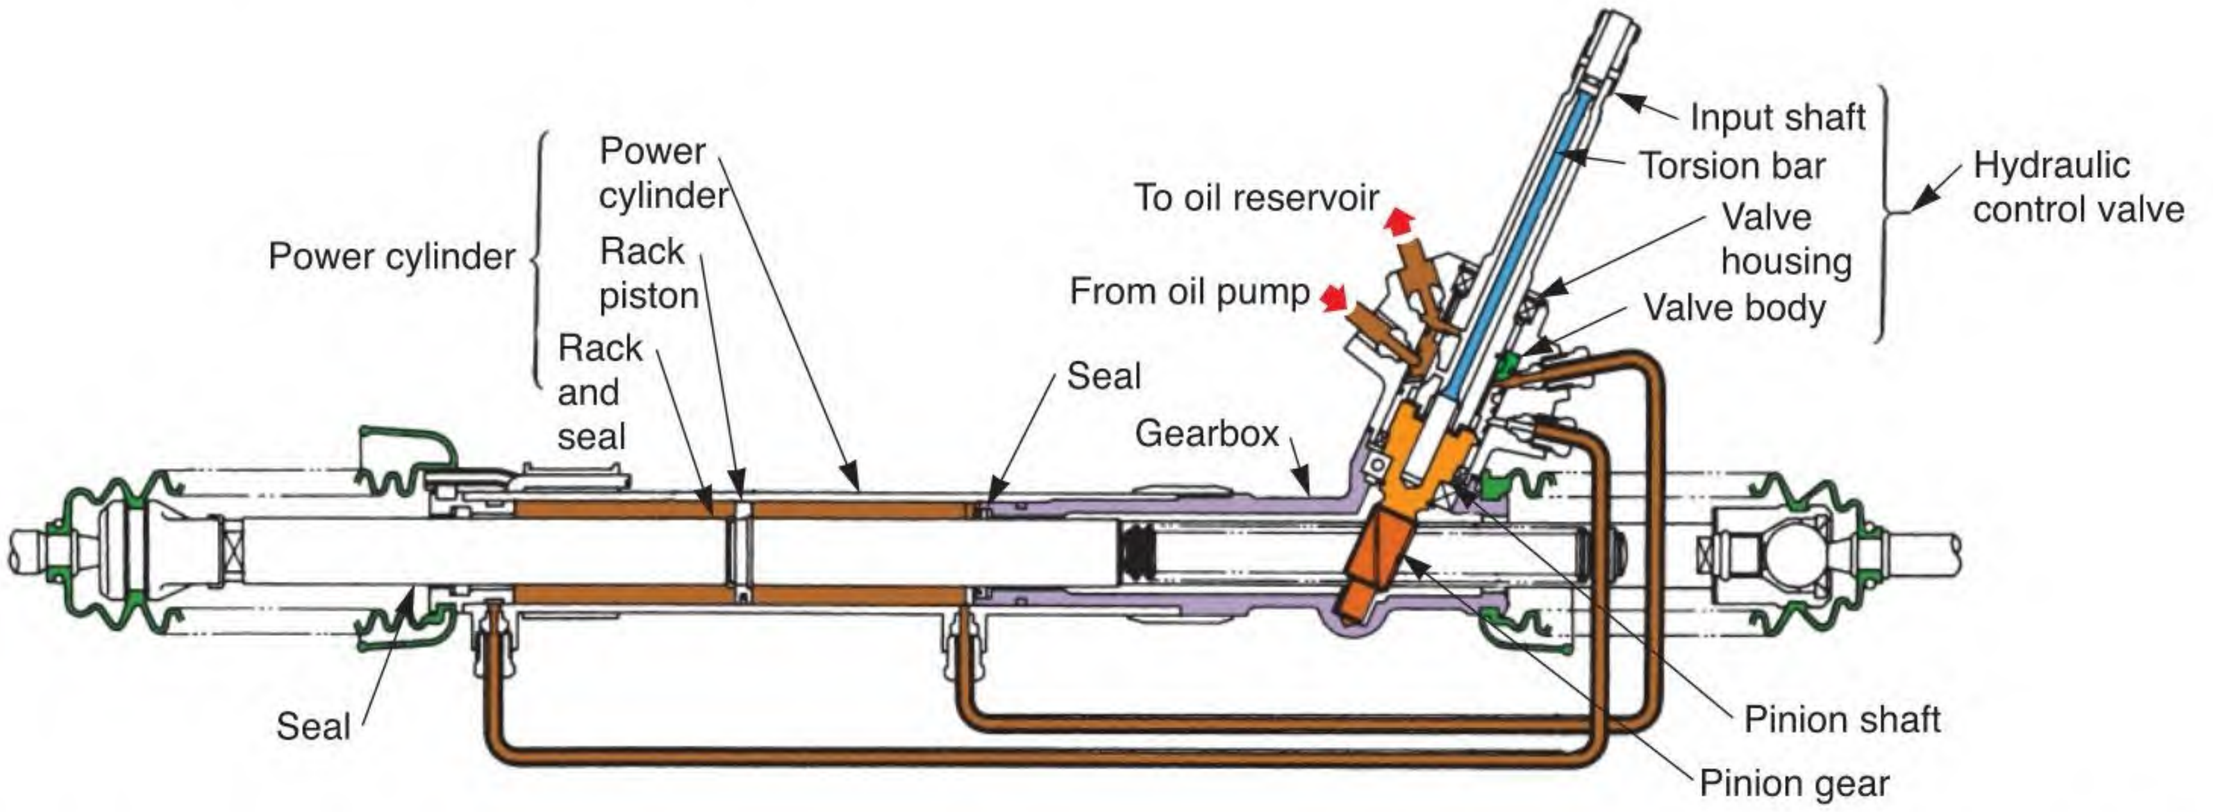
Power Rack-and-Pinion Control Valves

There are two types of control valve mechanisms used on power rack-and-pinion gears: rotary control valves and spool control valves. The rotary is more common.

The ***rotary control valve*** is operated by a torsion shaft connected to the pinion gear. Study **Figure 77-27** closely. It illustrates the operation of a power rack-and-pinion gear using a rotary control valve.

The thrust action of the pinion shaft shifts the ***spool control valve***. The control valve can then route oil to the power cylinder. Refer to **Figure 77-28**.

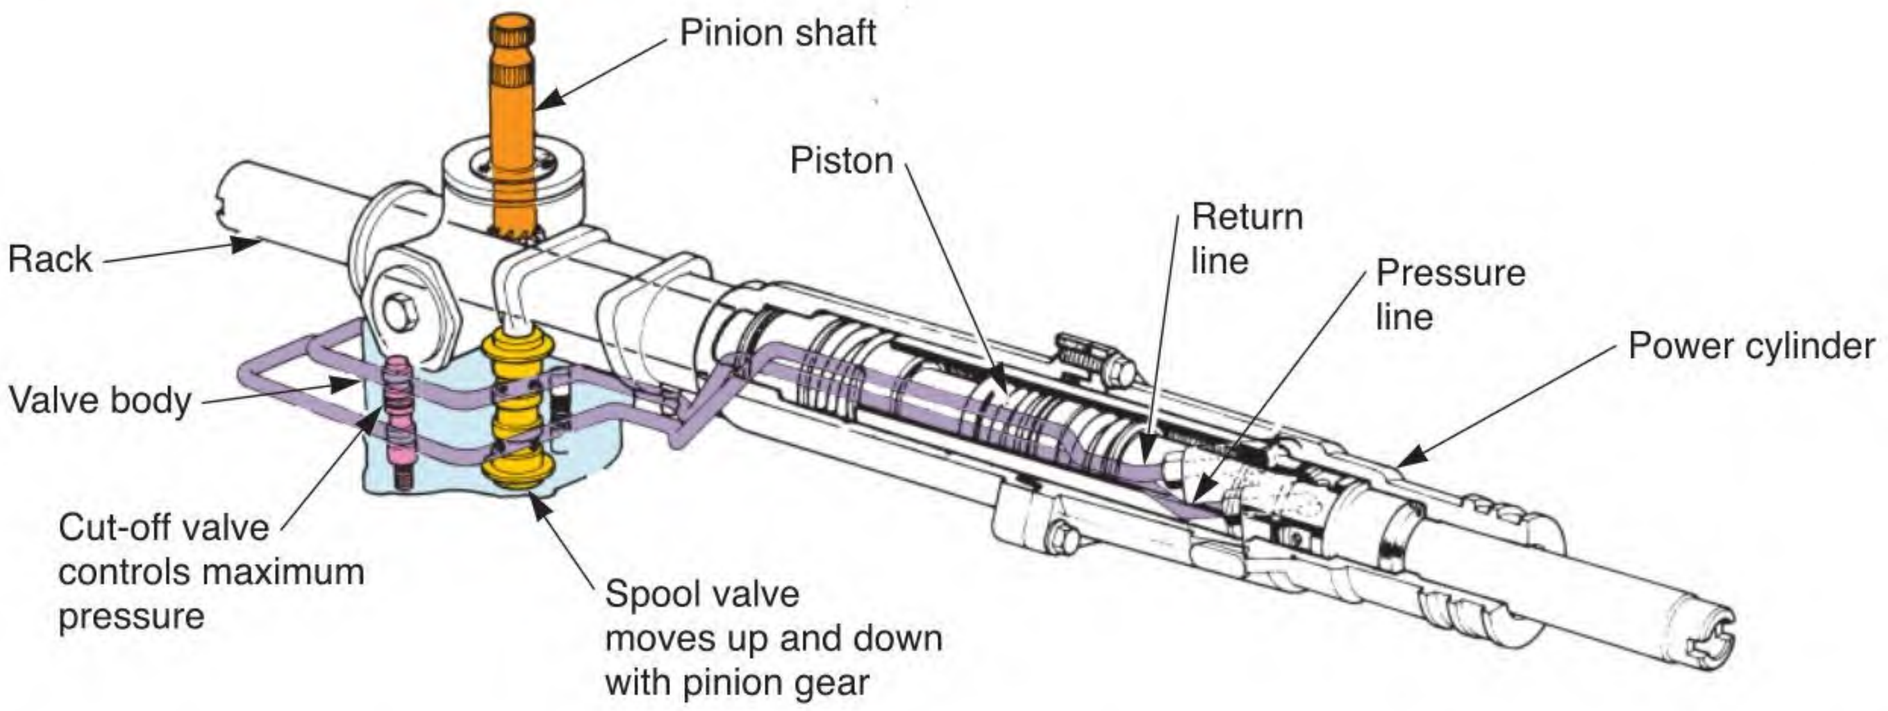
Power Rack-and-Pinion Operation



When the steering wheel is turned, the weight of the vehicle causes the front tires to resist turning. This twists a torsion bar (rotary valve mechanism) or thrusts the pinion shaft (spool valve mechanism) slightly. This makes the control valve move and align specific oil passages.

Pump pressure flows through the control valve, through the hydraulic line, and into the power cylinder. Pressure then acts on the power piston. The piston helps push the rack and the front wheels for turning. Refer to **Figure 77-29**.

Since the steering gear is filled with oil, the internal parts of the system are always lubricated. They slide or turn easily, with little friction and wear.



A ***power steering oil cooler*** is used to remove excess heat from the oil. It is usually a small metal line or radiator located in one of the power steering lines. Refer back to **Figure 77-21**.

Subaru

Figure 77-27. Study the parts of this modern power steering system.

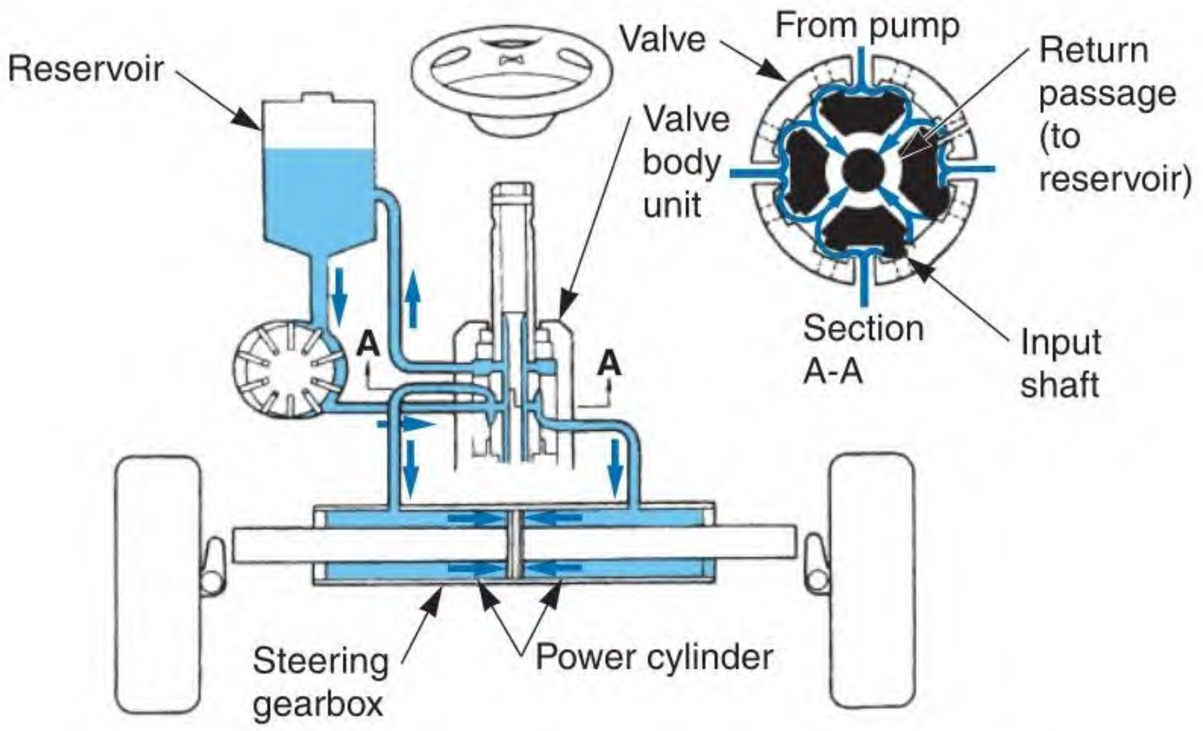
Honda

Figure 77-28. This power rack-and-pinion steering assembly uses a spool valve that detects thrust action of the helical pinion gear. It can then control oil pressure to the rack piston.

Electronic Steering Assist

Electronic steering assist uses a small electric motor to help move the rack-and-pinion gearbox. The motor is mounted inside the rack housing or on the steering column. The motor acts directly on the steering rack or steering column shaft. See **Figure 77-30**.

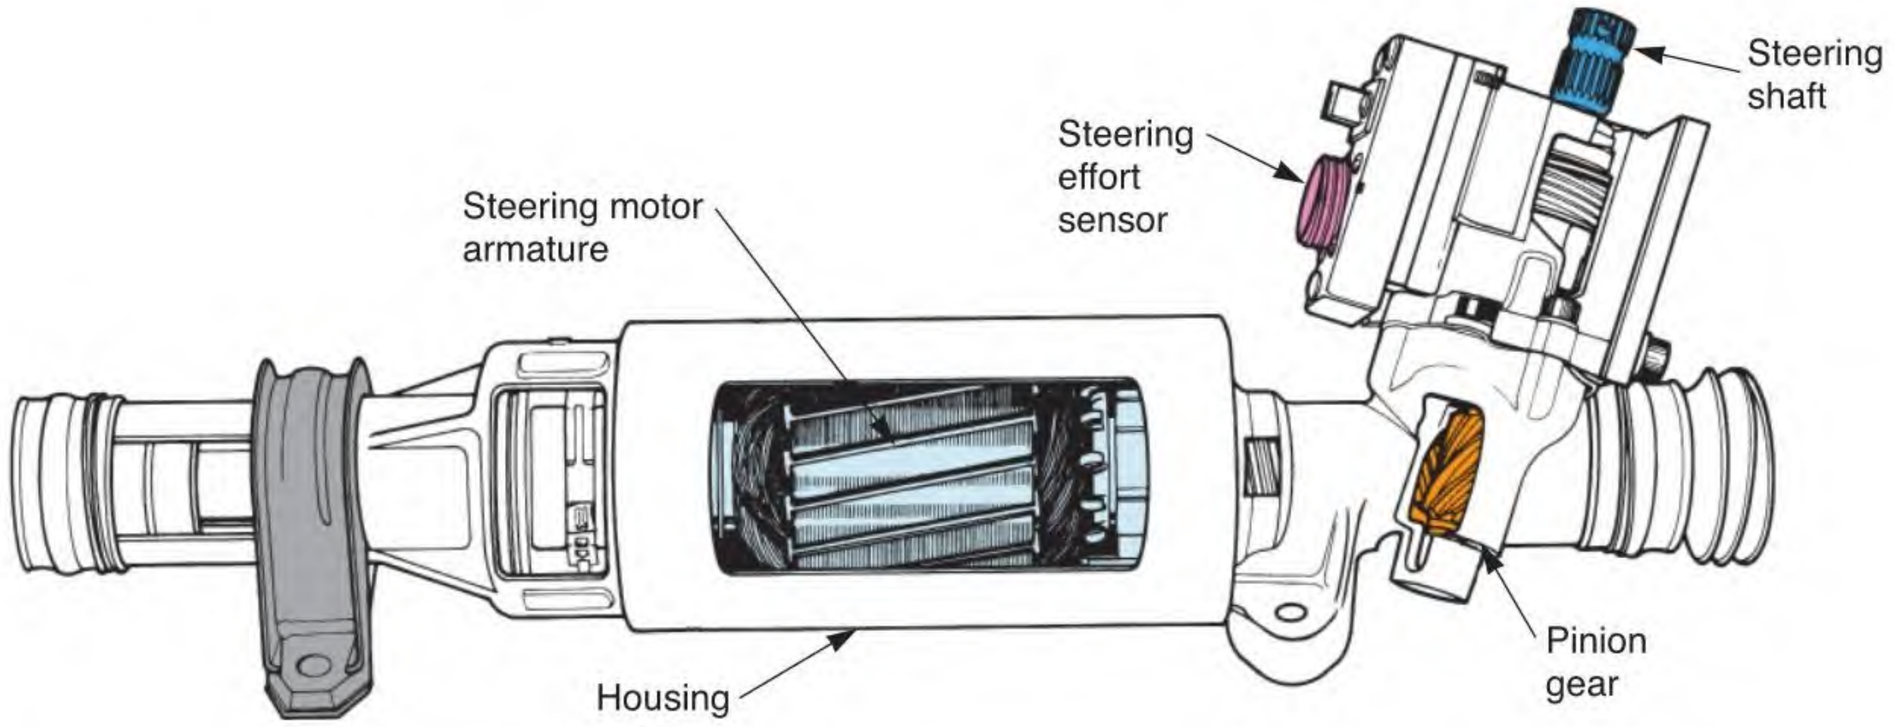
A steering control module electronically reacts to steering pressure to energize the rack motor to help move the rack left or right for steering. The steering control module can reverse motor rotation and alter motor speed as needed to help the driver steer the car.



An electronic steering mechanism eliminates the need for hydraulic steering assist and the bulky power steering pump, hoses, and hydraulic cylinder.

Tech Tip

Idle speed can be affected by the signal from the power steering pressure sensor. Some systems signal the hydraulic control module when the wheels are turned to full lock and higher-than-normal power steering system pressures are present. The control module can then operate the idle speed motor to prevent engine stalling.



A different design of electronic steering assist has a small electric drive motor, gearbox, clutch, and control circuit mounted inside the steering wheel. The assembly is mounted inside the center section of the steering

Copyright Goodheart-Willcox Co., Inc.

Honda

Figure 77-29. Study the operation of this speed-sensitive steering system. A—When driving at high road speeds, low power assist is desirable. Less force is needed to steer the wheels. B—When stopped or driving at low road speeds, more power assist is needed. Wheels resist turning more because of the high friction between the stationary tires and the road surface.

Moog

Figure 77-30. An electronic assist rack-and-pinion steering gear has a small electric motor inside the housing and a steering effort sensor on the steering shaft. The electric motor is used to supplement manual effort of the driver to turn the steering wheel and provide power assist. This system is much lighter and more compact than a conventional hydraulic power steering system.

Copyright Goodheart-Willcox Co., Inc.

wheel, underneath the driver's-side air bag. The power steering motor applies power assist directly to the top of the steering shaft. When the driver turns the wheel to the left or right, sensors detect torque in that direction and energize the small motor to help rotate the steering shaft in the same direction. This mounting location keeps the power assist motor away from road debris, moisture, dirt, snow, and ice. Refer to **Figure 77-31**.

Proportional Rack-and-Pinion Power Steering

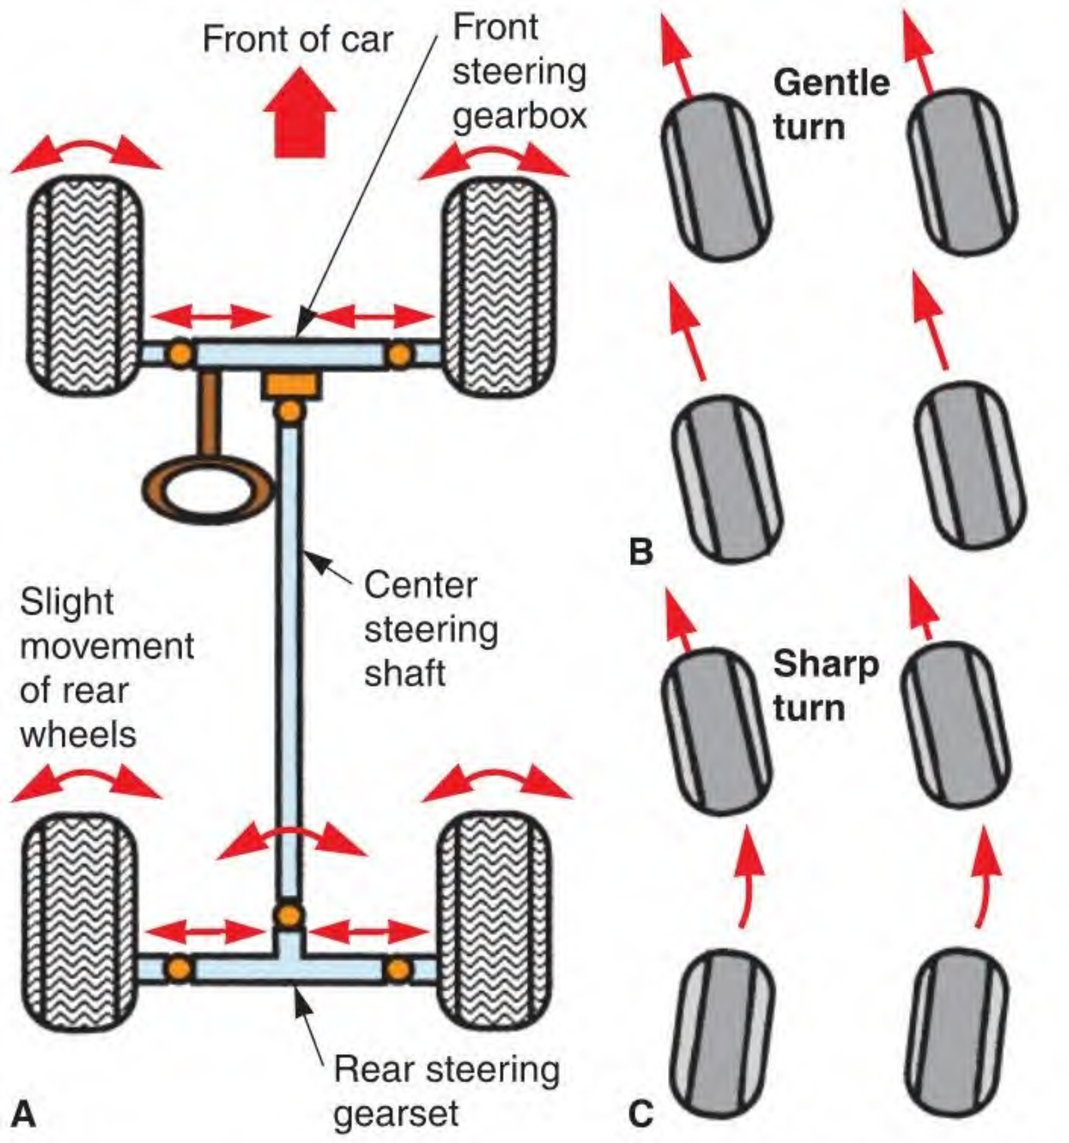
Proportional rack-and-pinion power steering senses vehicle speed and steering load to ensure adequate road feel (small road imperfections felt in steering wheel for more feedback). This type of system can also be called ***speed-sensitive power steering***.

Proportional steering systems alter steering wheel effort as road speed changes. They increase effort at higher speeds for more road feel. They also lower steering effort at low speeds to help the driver turn the steering wheel when parking.

In some systems, a computer-controlled electromagnet is mounted around the steering gear stub shaft. The stub shaft acts on a small torsion bar. The stub shaft and torsion bar operate the power steering valve, which controls fluid flow to the rack for power assist.

If the vehicle is not moving or is moving slowly, an electronic control module (computer) sends current through the electromagnet in one direction to help attract and pull on the stub shaft and torsion bar, increasing valve output pressure to make the vehicle easier to steer. Then, when the vehicle reaches road speed, the module reverses electrical flow through the electromagnet. This increases steering effort to improve road feel.

Other systems use a stepper motor or a solenoid to act upon the steering mechanism. The computer-operated stepper motor or solenoid helps shift the fluid valve to affect steering effort. The stepper motor is not as smooth or as variable as the electromagnetic-assist system.



Ford Motor Co.

Figure 77-31. The basic parts of a modern electronic steering assist system. The small reversible motor and control board mount around the steering shaft to apply motor torque to the shaft. If any part of the system fails, the motor is disengaged from the steering shaft so that the vehicle can still be steered but with slightly more turning effort by the driver.

Four-Wheel Steering Systems

Several automakers now provide four-wheel steering systems on their high-performance vehicles. Instead of just the front two wheels, all four wheels change direction to improve handling, stability, feel, and maneuverability. See **Figure 77-32**.

Goodehart-Willcox Publisher

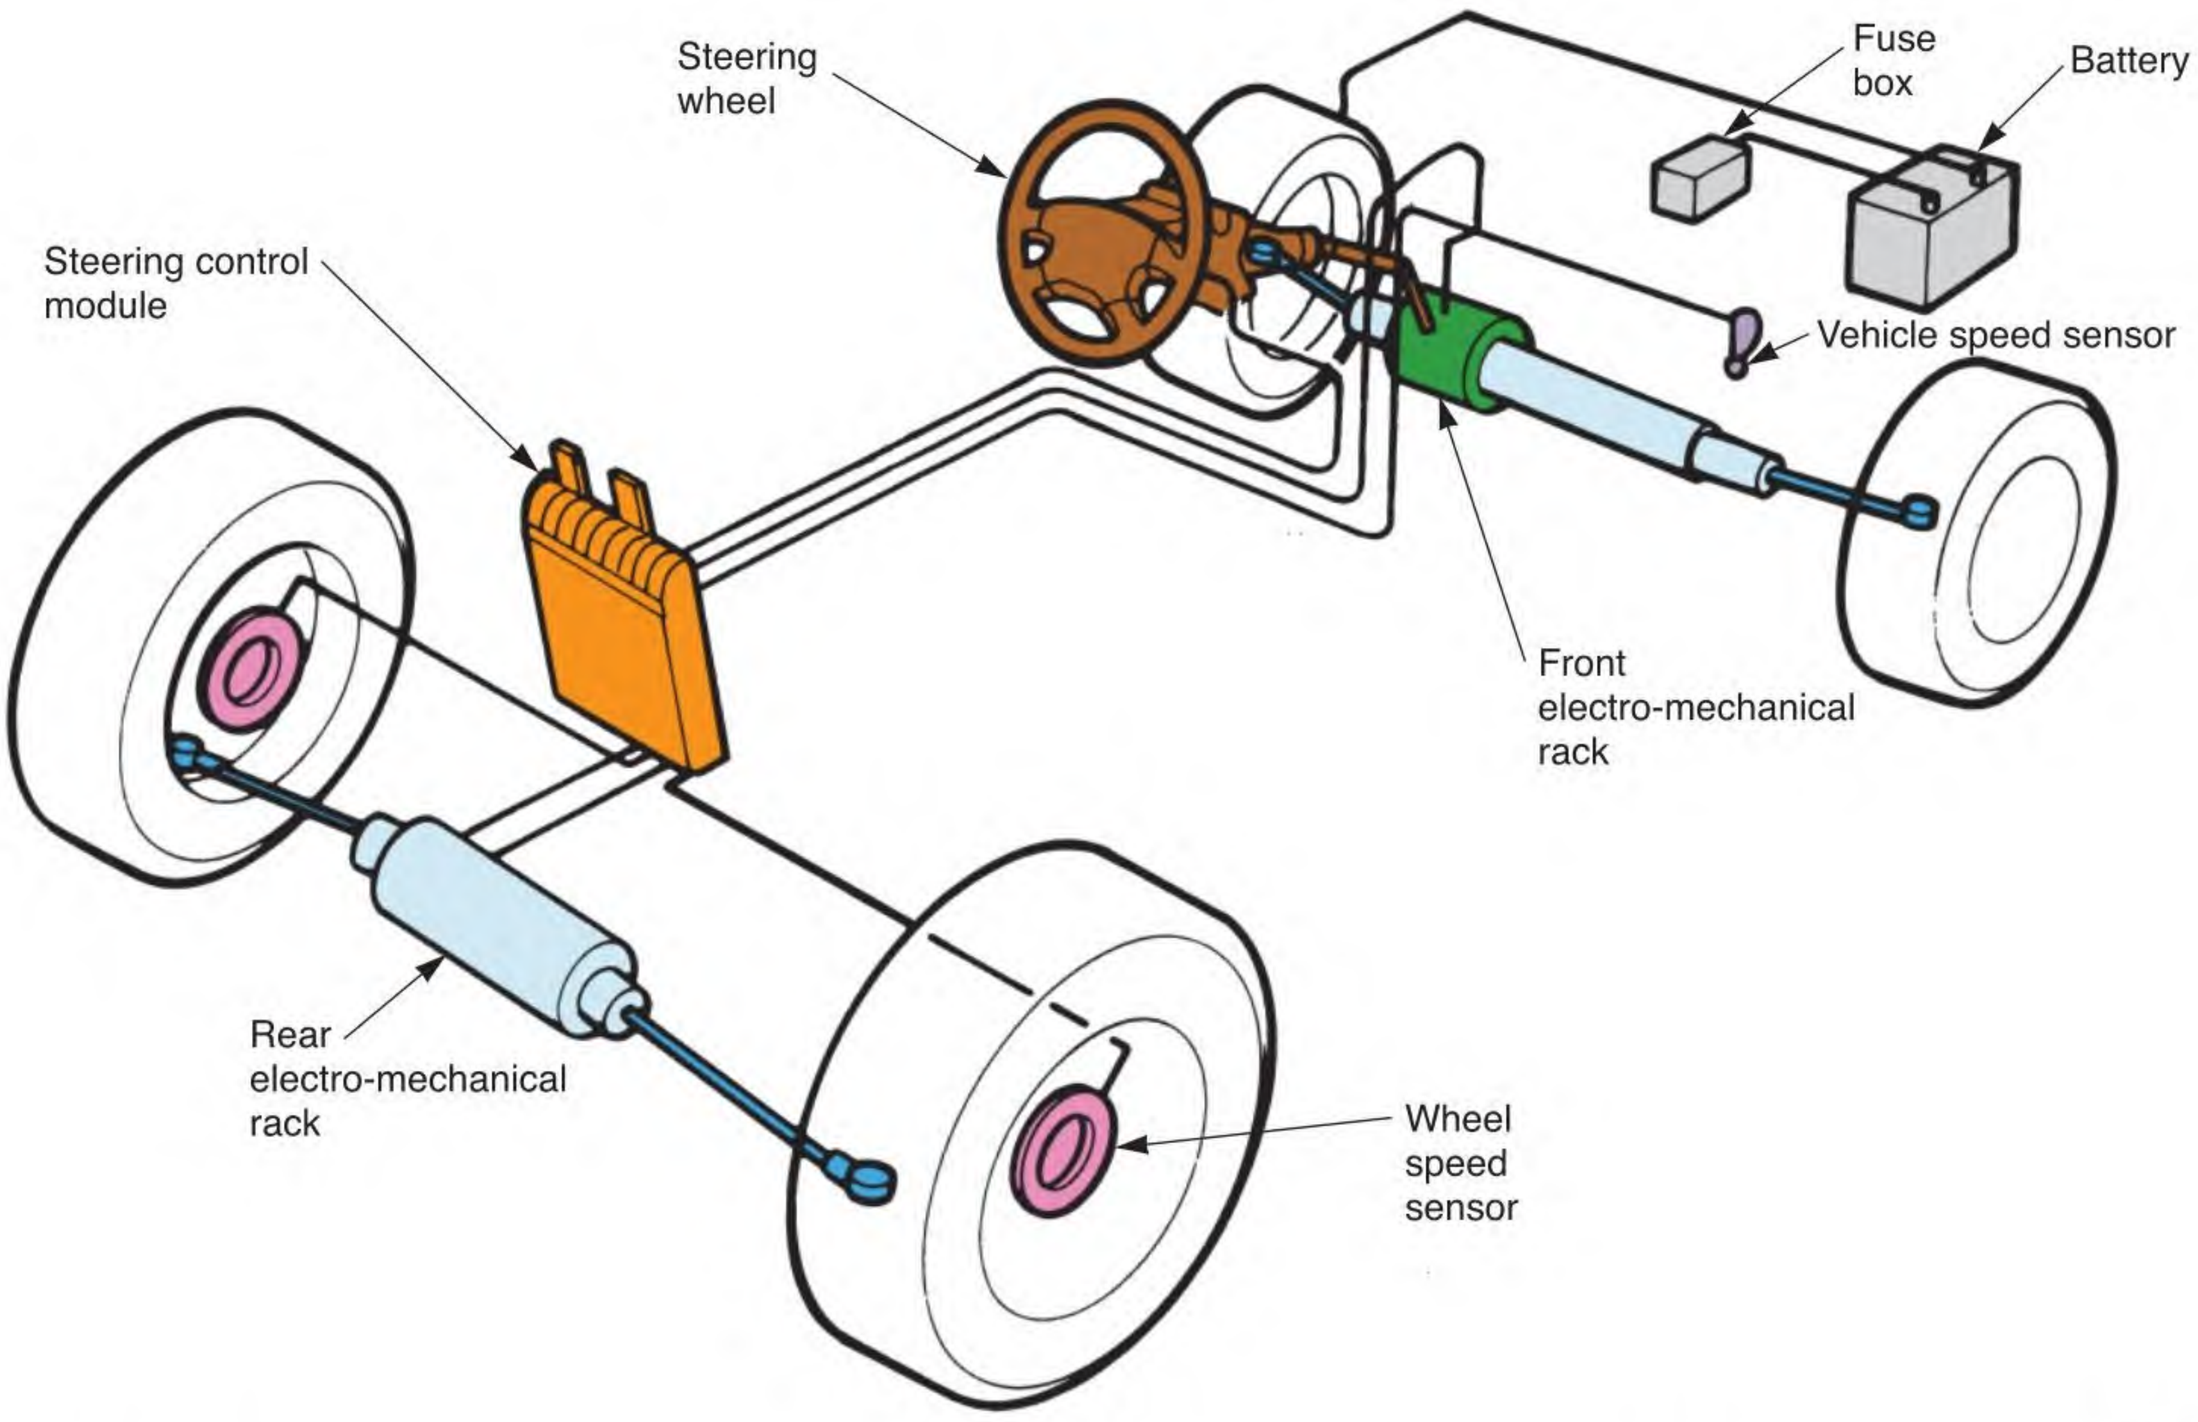
Figure 77-32. A—Note the basic parts of this four-wheel steering system. B—When the steering wheel is turned gently, the wheels pivot in the same direction. C—When the steering wheel is turned more sharply, the wheels pivot back and then turn in opposite directions.

Copyright Goodheart-Willcox Co., Inc.

There are three types of four-wheel steering systems: mechanical, hydraulic, and electronic.

The ***mechanical four-wheel steering system*** uses a special front rack-and-pinion gearbox with a transfer box. The transfer box operates a long shaft that extends back to the rear rack. When the front wheels are turned, the shaft rotates to turn the rear wheels. This was the first four-wheel steering system on the market.

A ***hydraulic four-wheel steering system*** uses a conventional power rack-and-pinion steering system up front. A vane pump forces fluid to the rack to provide power assist. Hydraulic lines extend back to a rear power steering pump, which is driven by the differential. Depending on vehicle speed, the rear pump forces fluid under pressure into a control valve.

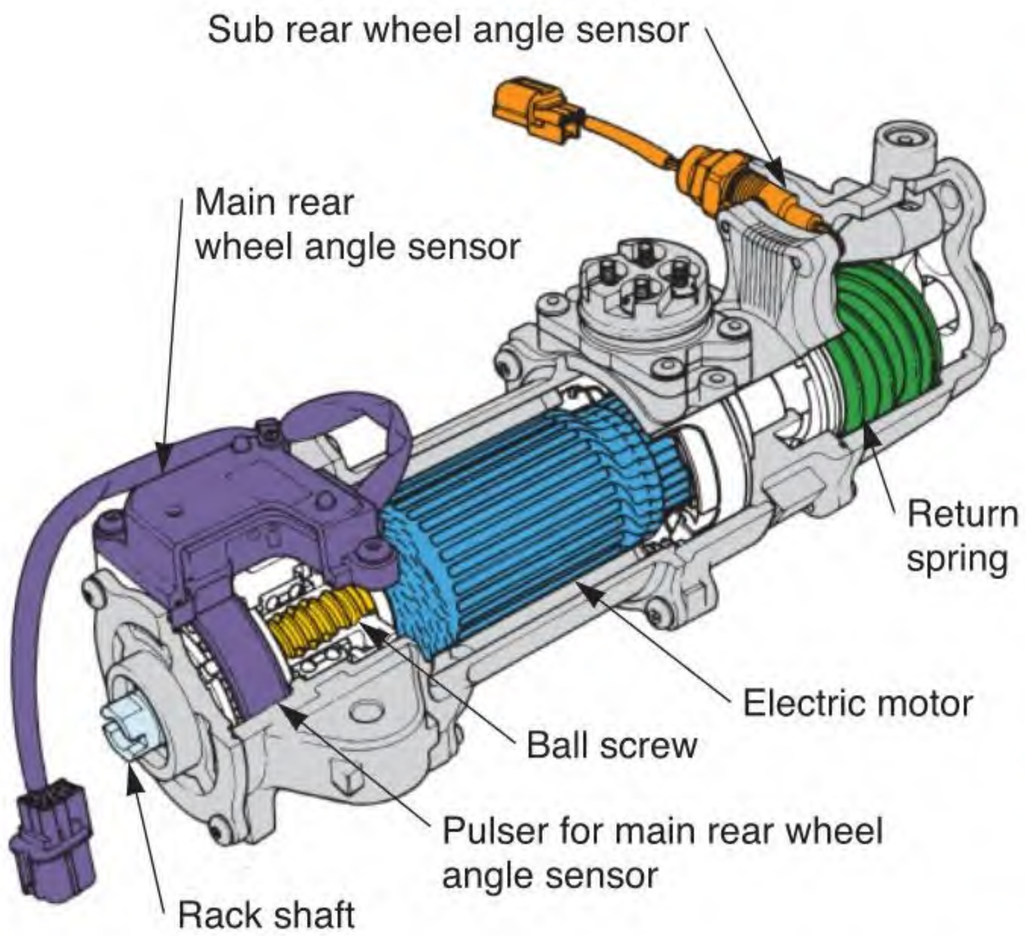


When a specific road speed is reached, the control valve can then operate the rear steering system. With this design, the rear rack tie-rod ends are attached to the suspension system's trailing arm. When activated, the rack shifts the trailing arm to steer the rear wheels.

Modern ***electronic four-wheel steering systems*** have an electric-motor-driven power rack that acts upon the rear wheels via its own recirculating-ball drive and mechanical links. See **Figure 77-33**.

An electronic control module controls rear-wheel steering angles. The module analyzes signals from angle sensors in the front steering, from wheel speed sensors in the anti-lock brake system, and from a yaw sensor.

The motor-driven power rack is then energized by the module to move the rear wheels as needed. The module energizes a dc motor inside the power rack. The motor powers a recirculating-ball drive to slide the rack right or left to respond to control module signals. Refer to **Figure 77-34**.



With a slight turn of the steering wheel, the four-wheel steering system turns the rear wheels in the same direction as the front wheels. However, during a sharp turn, the special gear box straightens out the rear wheels and then turns them in the opposite direction of the front wheels.

Honda

Figure 77-33. This is an electronically-controlled four-wheel steering system. A dedicated computer, or steering control module, is used to monitor and control this system.

Copyright Goodheart-Willcox Co., Inc.

Honda

Figure 77-34. This is the rear actuator, or electric power steering assist unit, for a four-wheel steering system. Note how it has rear wheel angle sensor built into the assembly. The electric motor operates a ball screw, which transfers turning force to the rack shaft.

Electronic systems also react to changes in vehicle speed. Generally, when at high speeds, the wheels steer in the same direction to improve maneuverability. At low vehicle speeds, the wheels steer in opposite directions to reduce turning radius.

Industry Trend

Automobile manufacturers are working to develop steer-by-wire systems. These systems eliminate the mechanical connection between the steering wheel and the vehicle's wheels. In a typical steer-by-wire system, the steering wheel sends electrical signals to a control module. Based on these signals, the control module operates actuators (electric motors) located at the wheels. The actuators move the wheels to steer the vehicle. Steer-by-wire systems will increase reliability, reduce system weight, and improve fuel economy.

Summary

- The steering system is vital to the safety of an automobile. It allows the driver to safely maneuver the vehicle.
- There are two basic kinds of steering systems in use today: linkage (worm gear) steering systems and rack-and-pinion steering systems.
- The steering column assembly consists of the steering wheel, steering shaft, steering column (outer housing), and, sometimes, ignition key mechanism, a flexible coupling, and a universal joint.
- To help prevent theft, late-model vehicles also have a locking steering wheel.
- Most vehicles use a collapsible steering column to help prevent driver chest and face injury during an auto accident.
- A tilt steering column has a flex joint, or U-joint, that allows the top half of the column and the steering wheel to be positioned at different angles or heights.
- The recirculating-ball gearbox is normally used with a linkage steering system on large trucks.
- Gearbox ratio, or steering gear reduction, is basically a comparison between steering wheel rotation and sector shaft rotation.
- The steering linkage is a series of arms, rods, and ball sockets that connects the steering gearbox to the steering knuckles.
- Ball sockets provide for motion in all directions between two connected parts.
- A manual rack-and-pinion steering gear basically consists of a pinion shaft, a rack, thrust spring, bearings, seals, dust boots, tie-rods, and a gear housing.
- Tie-rod assemblies for rack-and-pinion steering connect the ends of the rack with the steering knuckles.
- Power steering systems normally use an engine-driven pump and a hydraulic system to assist steering action. They can also use an electric motor in the rack or inside the steering wheel to provide power assist.
- A power cylinder for rack-and-pinion steering is a precisely machined tube that accepts the power piston.

Copyright Goodheart-Willcox Co., Inc.

- Proportional rack-and-pinion power steering senses vehicle speed and steering load to ensure adequate road feel at the steering wheel.
- In a four-wheel steering system, all four wheels change direction to improve handling, stability, feel, and maneuverability.

Activities

1. Examine a vehicle in the shop and determine what type of power steering system it has.
2. Identify the major parts of a vehicle's power steering system.
3. Use an Internet-connected computer or tablet to look up various types of modern steering systems and research automated vehicle steering advancements.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Name five functions of the steering system.
2. List and explain the six major parts of a linkage-type steering system.
3. Define the term *road feel*.
4. In addition to the steering column, shaft, and wheel, list and explain the four major parts of a manual rack-and-pinion steering system.
5. Today's vehicles commonly use a(n) _____ steering column to help prevent driver injury during an accident.

Copyright Goodheart-Willcox Co., Inc.

6. Which of the following is *not* a part in a recirculating-ball steering gearbox?
   (A) Universal joint.
   (B) Worm shaft.
   (C) Sector shaft.
   (D) Ball nut.
7. Define the term *gearbox ratio*.
8. The idler arm supports the pitman arm on the passenger side of the vehicle. True or False?
9. What is the purpose of tie-rods on a rack-and-pinion steering system?
10. _____-and-_____ is the most popular type steering system used on modern vehicles.
11. Power steering systems normally use an engine-driven _____ and a(n) _____ system to assist steering action.
12. A pressure-relief valve is used in a power steering system to control maximum oil pressure. True or False?
13. Describe an integral-piston power steering system.
14. List and explain the four major parts found on a power rack-and-pinion steering system but not on a manual rack-and-pinion system.
15. How does electronic steering assist work?

ASE-Type Questions

1. Technician A says one of the functions of an automotive steering system is to transmit "road feel" to the driver's hands. Technician B says one of the functions of a steering system is to prevent excessive "body squat." Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says a steering shaft transfers turning motion from the steering wheel to the steering column. Technician B says a steering shaft transfers turning motion from the steering wheel to the steering gearbox. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says an automotive steering linkage connects the steering gearbox to the steering wheel. Technician B says a steering linkage connects the steering gearbox to the steering knuckles and wheels. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. All of the following are basic components of a linkage steering system *except:*
   (A) steering gearbox.
   (B) steering rack.
   (C) steering shaft.
   (D) ball sockets.
5. Technician A says power steering gearbox ratios will be higher than manual steering gearbox ratios. Technician B says tie-rod assemblies are used in rack-and-pinion steering systems. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says tie-rod assemblies for rack-and-pinion steering connect the ends of the pitman arms with the steering knuckles. Technician B says tie-rod assemblies for rack-and-pinion steering connect the ends of the rack with the steering knuckles. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says a Woodruff key is used to lock the steering wheel to the steering shaft. Technician B says splines are used to lock the steering wheel to the steering shaft. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

8. Technician A says an automotive ignition switch is usually bolted to the steering column. Technician B says special clamps are normally used to secure an automotive ignition switch to the steering column. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says a steel mesh collapsible steering column is a one-piece unit. Technician B says a steel mesh collapsible steering column is a two-piece unit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says a pitman arm is a component of a parallelogram linkage. Technician B says an idler arm is a component of a parallelogram linkage. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
11. Technician A says "worm gear" steering systems are used on most modern automobiles. Technician B says rack-and-pinion steering systems are used on most late-model automobiles. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
12. Technician A says screws are used to secure a rack-and-pinion steering system's rubber dust boots. Technician B says clamps are used to secure a rack-and-pinion steering system's rubber dust boots. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
13. Technician A says that power steering hoses connect the power steering pump to the tie-rod assemblies in a rack-and-pinion system. Technician B says a belt running from the engine's crankshaft normally powers an automobile's power steering pump. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
14. Technician A says a speed-sensitive steering system uses a control module (computer) in its design. Technician B says that when making a sharp turn with an electronic four-wheel steering system, the rear wheels will turn in the opposite direction of the front wheels. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
15. A new electric rack-and-pinion steering system is needed to repair a badly worn and leaking system. The new rack assembly costs $345 with 7% tax to be included. The labor time is 3.5 hours at $75 per hour. What is the total cost of the repair?
   (A) $510.55
   (B) $369.15
   (C) $607.50
   (D) $631.65

Chapter 78
Steering System Diagnosis and Repair

After studying this chapter, you will be able to:

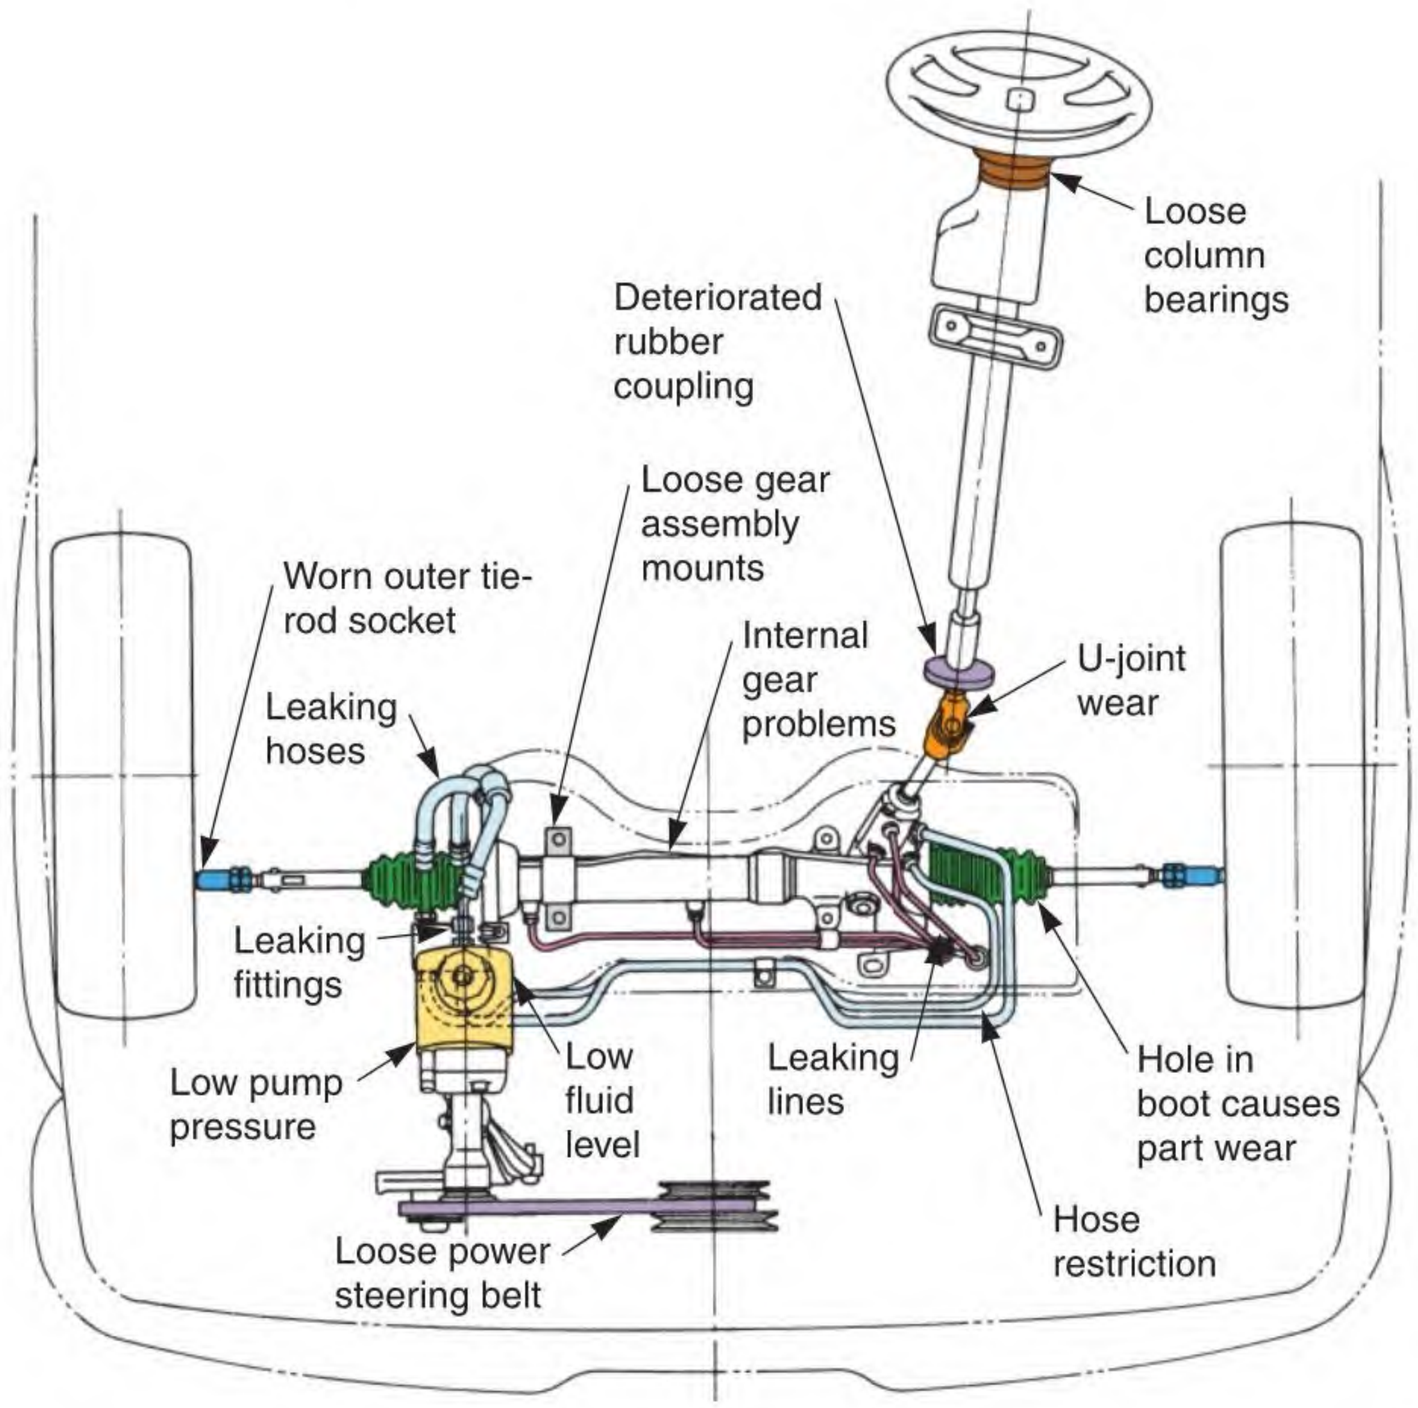
- Describe common steering system problems.
- Properly inspect and determine the condition of a steering system.
- Service power steering belts, hoses, and fluid.
- Explain basic steering column repair operations.
- Adjust rack-and-pinion gears.
- Describe service and repair procedures for a rack-and-pinion steering gear.
- Explain how to complete basic power steering tests.
- Describe power steering gear and pump service practices.
- Diagnose electronic assist power steering systems.
- Correctly answer ASE certification test questions about the diagnosis and repair of today's steering systems.

After prolonged use, the steering system gearbox, ball sockets, belts, hoses, and other system parts can wear. This can cause play in the steering system. The vehicle can wander from side to side when the driver is holding the steering wheel straight. This can render the vehicle unsafe to drive. It is important that the steering system be kept in perfect working condition to prevent an accident.

As a technician, it is your job to find and correct steering system troubles. This chapter will help you develop the most important skills for troubleshooting and repairing all types of automotive steering systems.

Steering System Problem Diagnosis

The most common steering system problems are play in the steering wheel, hard steering, and abnormal noises when turning the steering wheel. These problems normally point to part wear, lack of lubrication, or an incorrect adjustment. You must inspect and test the steering system to find the source of the trouble. Refer to **Figure 78-1**.



Steering Wheel Play

The most frequent of all steering system problems is excessive play in the steering wheel. ***Steering wheel play*** is normally caused by worn ball sockets, a worn idler arm, or too much clearance in the steering gearbox (worm or rack-and-pinion types).

Typically, you should *not* be able to turn the steering wheel more than about 1 1/2″ (38 mm) without causing movement of the front wheels. If the steering wheel rotates excessively without moving the wheels, a serious steering problem exists.

The ***dry park test*** is an effective way to check play in the steering linkage or the rack-and-pinion

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 78-1. Study the types of problems that can develop in a modern steering system.

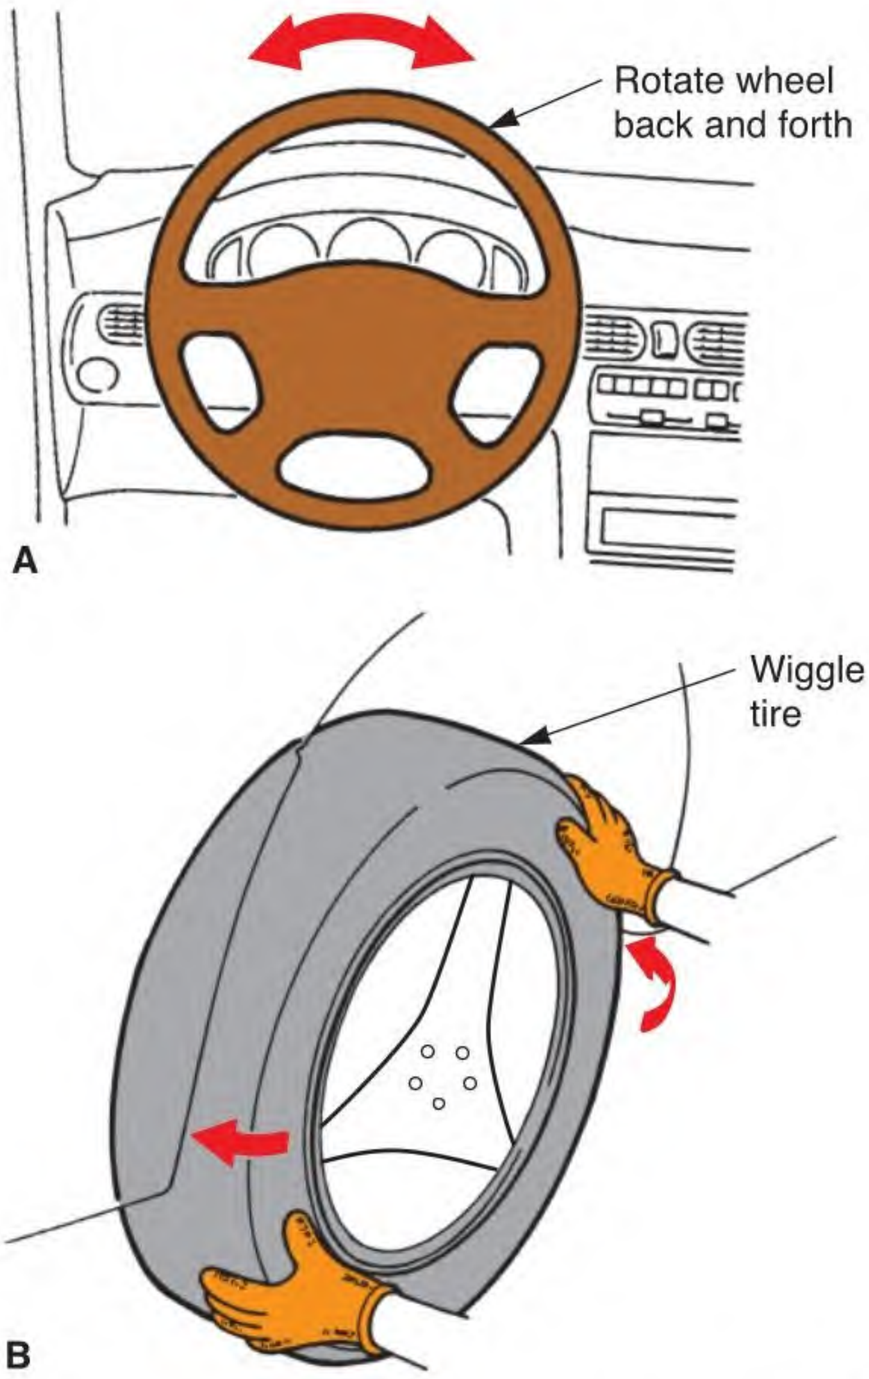
mechanism. With the full weight of the vehicle on the wheels, ask someone to rock the steering wheel back and forth while you look for looseness in the steering system.

You can also place the vehicle on a lift to inspect the steering parts for wear. Have someone wiggle one of the tires right and left as you look for play between parts. See **Figure 78-2**.

Start your inspection at the steering column shaft and work your way out to the tie-rod ends. Make sure that movement of one steering part causes an equal amount of movement of the adjoining steering part.

In particular, watch for ball studs that wiggle in their sockets. With rack-and-pinion steering, you must squeeze the rubber boots and feel the inner tie-rods to detect wear and play. If the tie-rod moves sideways (parallel with rack), the socket is worn and should be replaced.

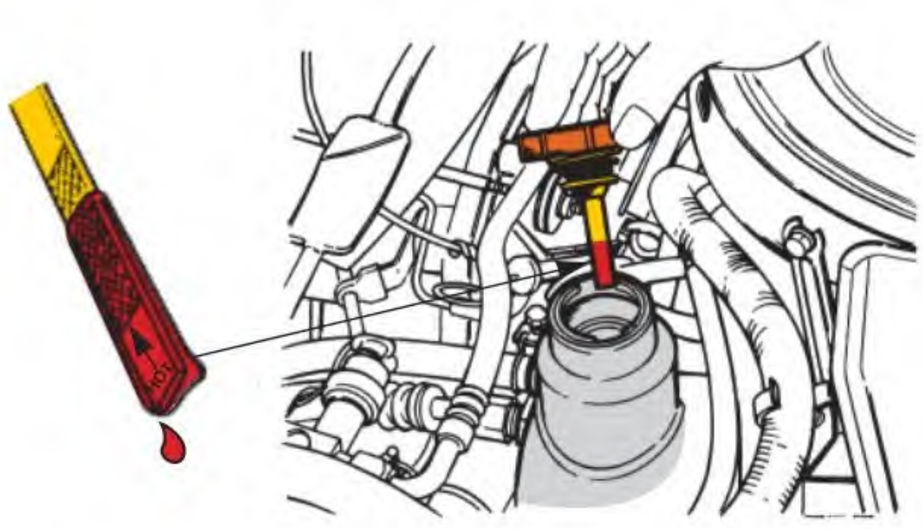
Hard Steering



Hard steering (steering that requires excessive effort) can be caused by problems with the steering gearbox, the rack-and-pinion steering gear, the power steering components, the ball sockets, and the suspension system.

Power steering systems commonly suffer from hard steering. When this occurs, check the fluid level in the power steering pump. If the fluid level is low, inspect the system for leaks. Also, check the power steering pump belt. If the belt is slipping, hard steering could result. Look at **Figure 78-3**.

Steering System Noise



Steering system problems can produce abnormal noises. Steering system noise can be a sign of worn parts, unlubricated bearings or ball sockets, loose parts, slipping belts, a low power steering fluid level, or other system troubles.

Copyright Goodheart-Willcox Co., Inc.

Honda and Mazda

Figure 78-2. Check all steering parts for wear carefully. A—With the vehicle on the ground, rotate the steering wheel back and forth while someone watches for part wear. B—You could also raise the vehicle on a lift and wiggle the tires back and forth while watching for steering play.

Subaru

Figure 78-3. A visual inspection will identify many power steering problems. If a dipstick is used, check the power steering fluid level as shown in the illustration. If low, check for leaks and add the correct type and amount of fluid. Also always check power steering belt condition and tension.

Belt squeal is a loud screeching sound produced by a slipping belt. A slipping power steering belt usually shows up when turning the steering wheel. Turning the steering wheel to the full right or full left position increases system pressure and can cause belt squeal.

Power steering pump noise is usually a loud whine that only occurs when you turn the steering wheel. It is often due to a low fluid level and air in the system. When fluid is added, the noise should go away after turning the wheels from full right to full left several times.

Steering System Maintenance

Steering system maintenance typically involves checking for low fluid level, belt problems, system leaks, and other troubles. It may also include lubricating (greasing) ball sockets.

Tech Tip

The safety of the vehicle and its passengers depends on the condition of the steering system. Always take steering system repairs seriously.

Checking Power Steering Fluid

To check the level of fluid in the power steering system, the engine should *not* be running. Set the parking brake and place the transmission in park or in neutral.

If the vehicle is equipped with a see-through reservoir, simply compare the fluid level to the markings on the side of the reservoir.

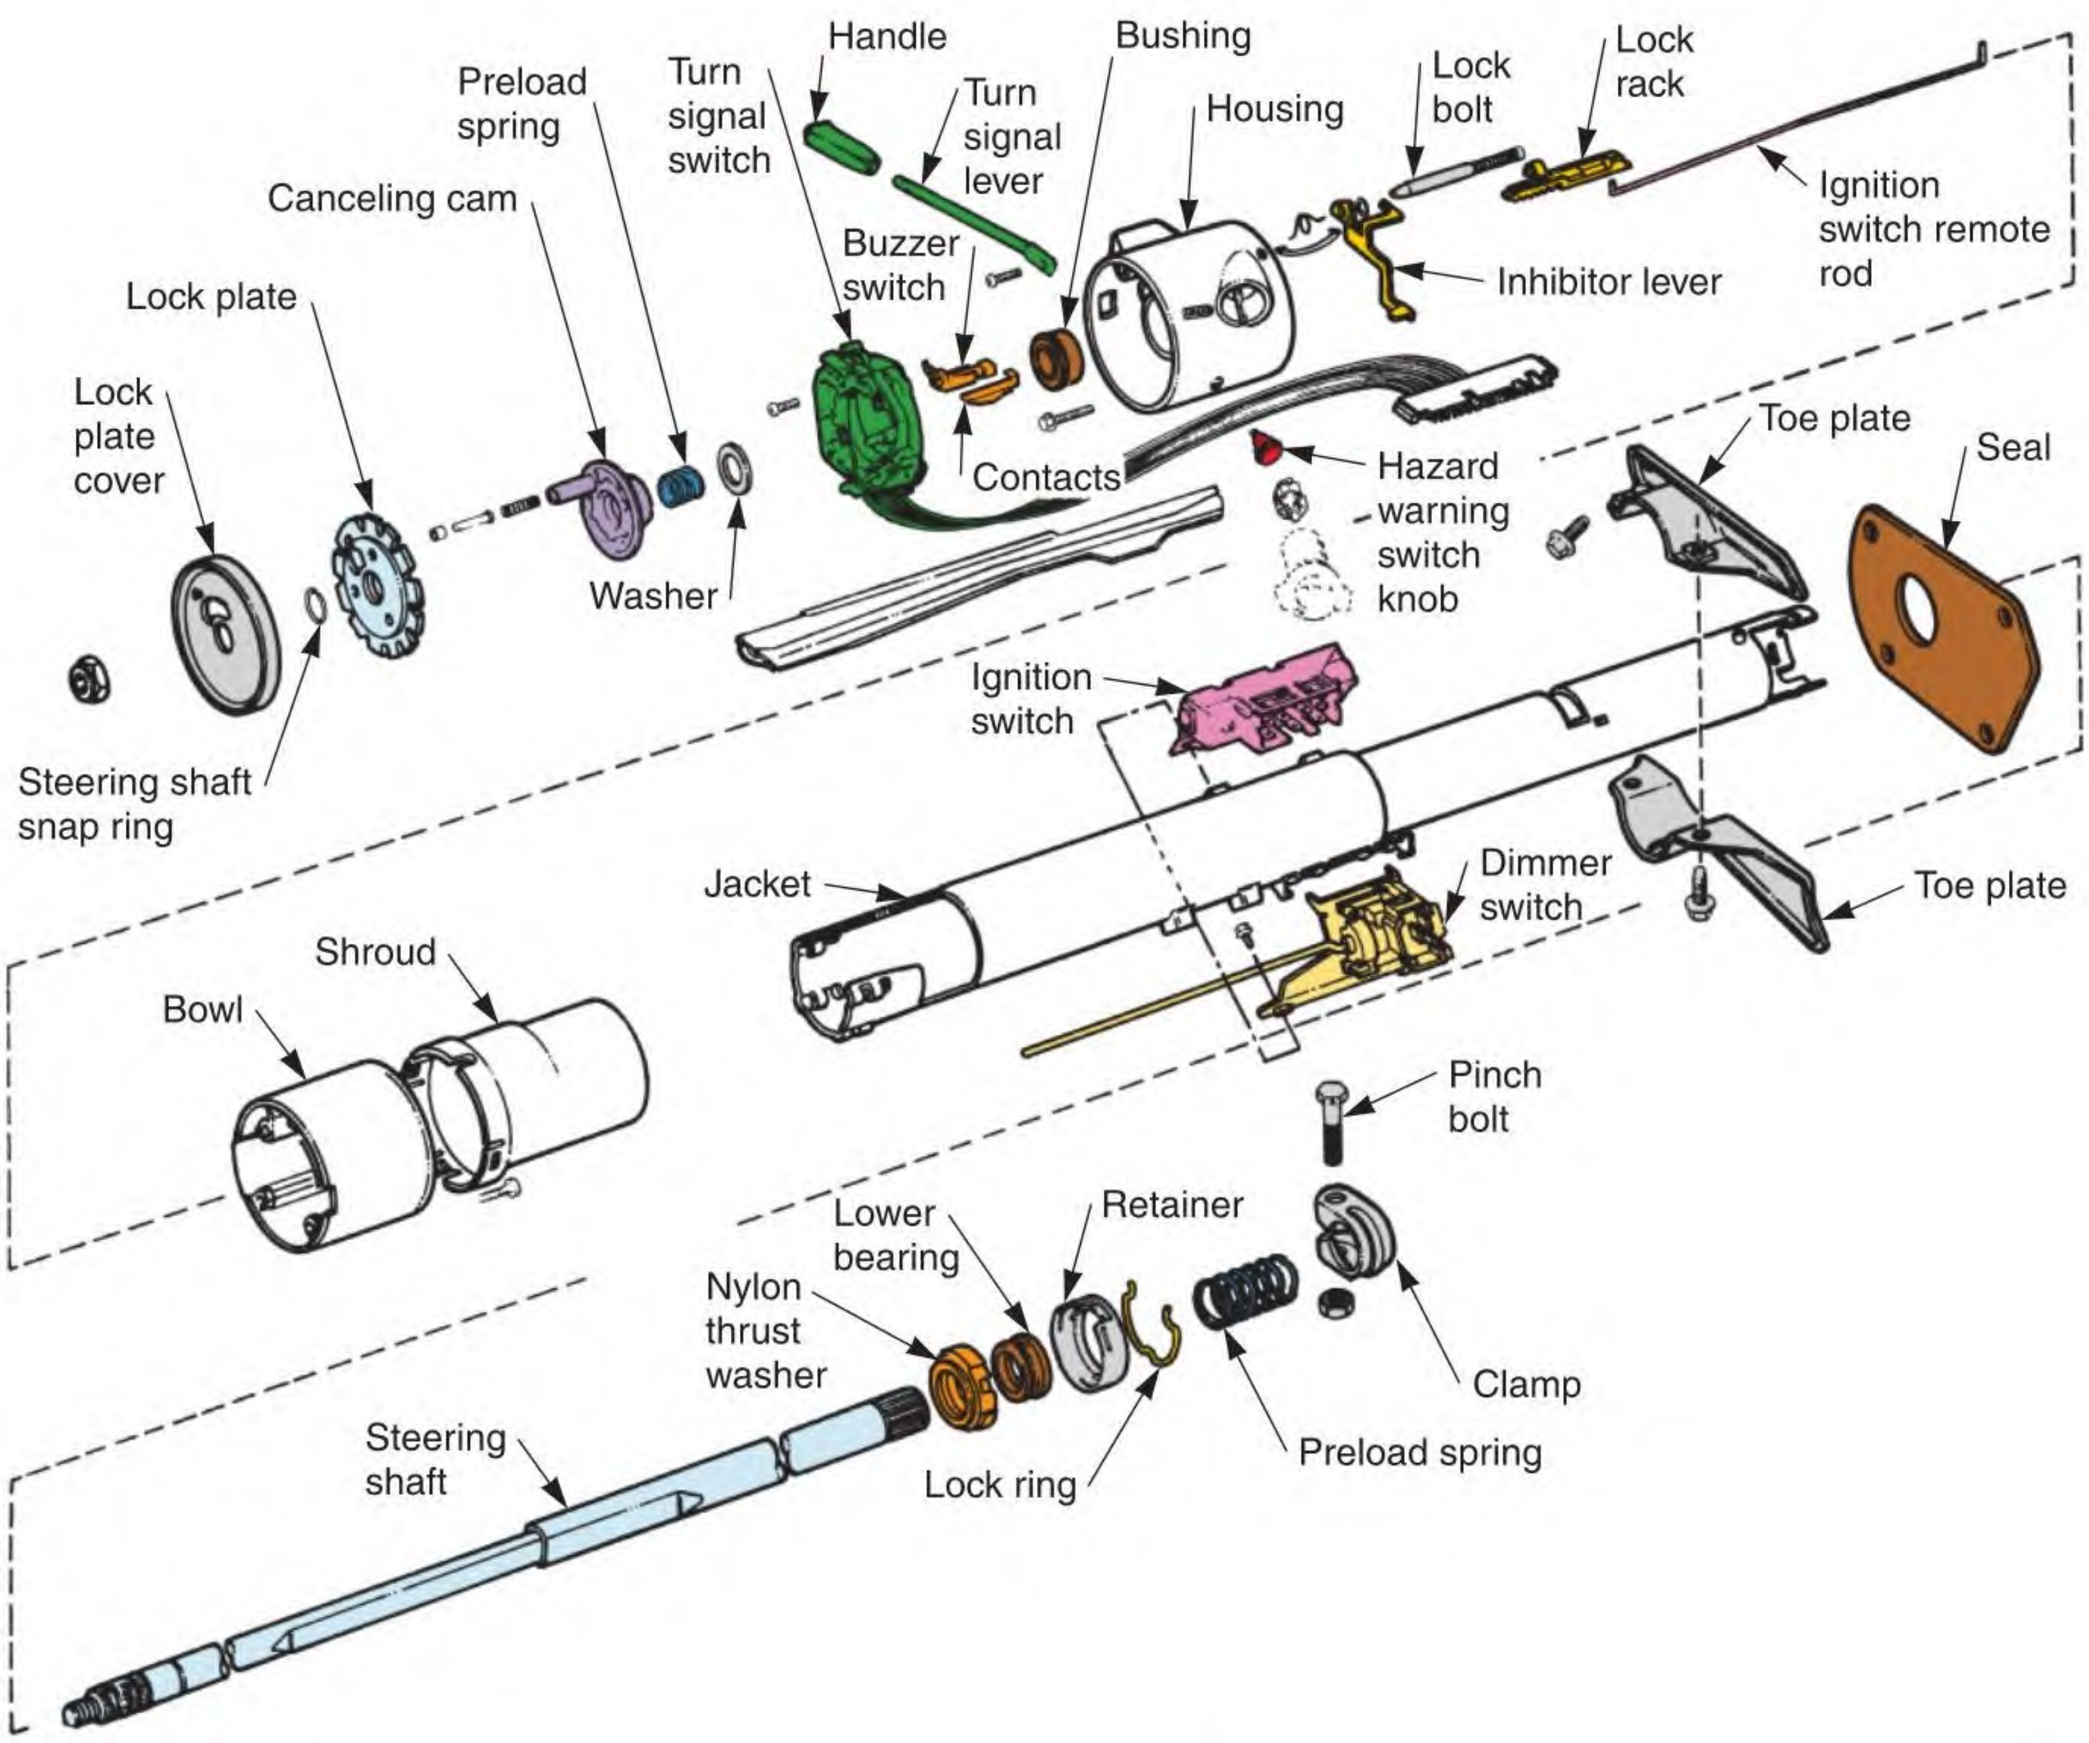
In some vehicles, the level must be checked using a dipstick that is part of the power steering reservoir cap. Unscrew and remove the cap from the power steering reservoir. Wipe off the dipstick and reinstall the cap. Remove the cap and inspect the level of fluid on the stick, as shown in **Figure 78-3**.

Most power steering dipsticks have markings for checking the fluid when *hot* and *cold*. Make sure you read the correct marking on the dipstick. The fluid level rises on the stick as the system warms.

If needed, add only enough fluid to reach the correct mark on the dipstick or the side of the reservoir. Do *not* overfill the system. Overfilling could cause fluid to spray out the top of the reservoir onto the engine and other components.

Copyright Goodheart-Willcox Co., Inc.

Servicing Power Steering Belts



A loose power steering belt can slip, squeal, and cause erratic or high steering effort. A worn or cracked belt may snap, causing a loss of power assist. Always inspect the belt very closely.

To remove a serpentine belt, use a breaker bar to swing the belt tensioner sideways and release tension. Pull the belt off its pulleys. Check the condition of all idler pulleys by spinning them with your fingers. If any feel dry and rough, replace the pulley. Damaged, worn, or loose idler pulleys can cause the new belt to fail prematurely.

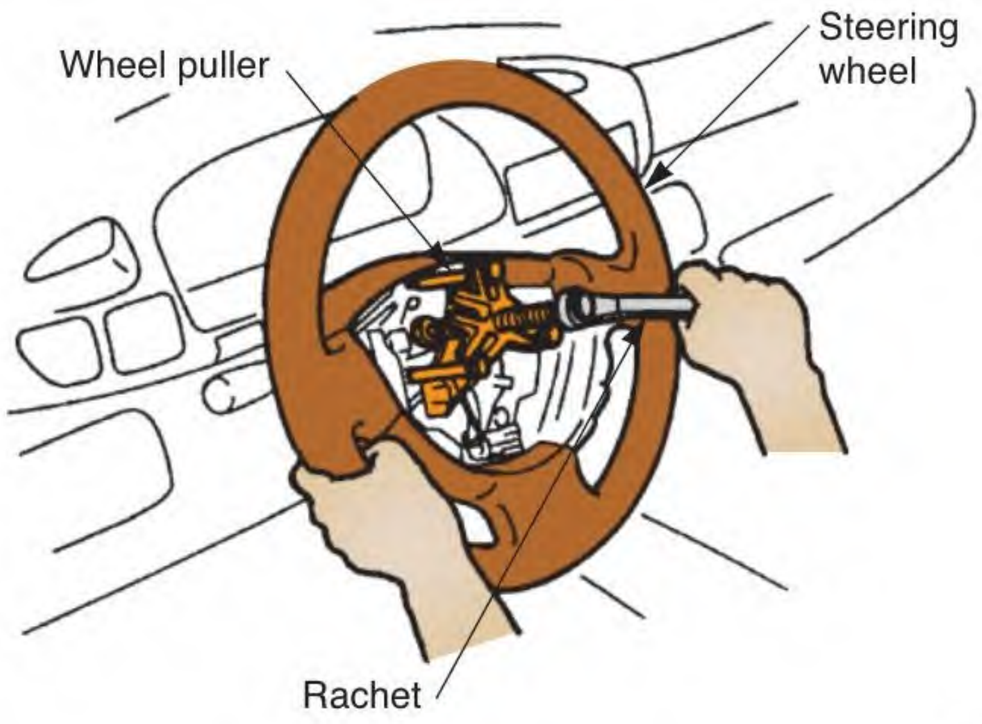
Before installation, compare the lengths and widths of the old and new belts. See vehicle service information or a belt diagram sticker on the engine bay frame for the correct belt path and work the new belt over its pulleys. After you position the belt, use the breaker bar again to swing the belt tensioner sideways so the new belt will fit over the tensioner pulley. Double-check that the new belt is tight and properly installed against all pulleys. Then start the engine and check belt operation.

Steering Column Service

Steering column service is needed after a collision (crushing of collapsible steering column) or when internal parts of the column fail. Most steering column repairs can be done with the column mounted in the vehicle. However, some repairs require that the steering column be removed. Refer to **Figure 78-4**.

Chrysler

Figure 78-4. This exploded view shows the relationship between the parts of a steering column.



Copyright Goodheart-Willcox Co., Inc.

Warning
When disassembling a steering column, follow the manufacturer's precautions concerning air bag deployment.

Steering Wheel Removal and Replacement

Before servicing the steering wheel, disconnect the battery to prevent accidental air bag deployment. Follow the manufacturer's instructions to remove the air bag unit. Remove the horn button and the steering shaft nut. Scribe alignment marks on the steering wheel and the steering shaft to help you correctly position the steering wheel during reassembly. Many steering shafts and wheels have a distinctly shaped spline and matching indentation to prevent the steering wheel from being reinstalled incorrectly.

A ***wheel puller*** is used to remove a steering wheel from its shaft. Mount the wheel puller as shown in **Figure 78-5**. Screw the bolts into the threaded holes in the steering wheel. Make sure the bolts have the correct thread type. Use a wrench or ratchet to tighten the puller down against the steering shaft to remove the wheel.

Mazda

Figure 78-5. A wheel puller is normally needed to force the steering wheel off its shaft. Wear safety glasses while tightening the center puller bolt.

Warning
Wear eye protection when tightening a wheel puller. If one of the bolts were to break, bits of metal could fly into your face.

Follow service manual directions to replace the worn or damaged parts in the steering column (upper steering shaft bearing, turn signal assembly, etc.). Assemble the column in the reverse order of disassembly.

Steering Column Joint Replacement

Many steering column assemblies use a flexible coupling or a universal joint on the lower part of the steering shaft. The flexible coupling is normally made of reinforced rubber. The rubber coupling can deteriorate after prolonged service or long-term exposure to engine heat or oil. The metal universal joint can wear and develop play after prolonged service.

Steering Linkage Service

Carefully inspect steering linkage components for signs of wear. Common signs of wear in steering linkage components include:

- Excessive play in the idler arm.
- Looseness in ball sockets.
- Worn tie-rods.
- Damaged adjuster tube.
- Bent center link.
- Worn pitman arm splines.
- Misadjusted nut.
- Worn joint in tie-rods.
- Loose mounting bolts.

Idler Arm Service

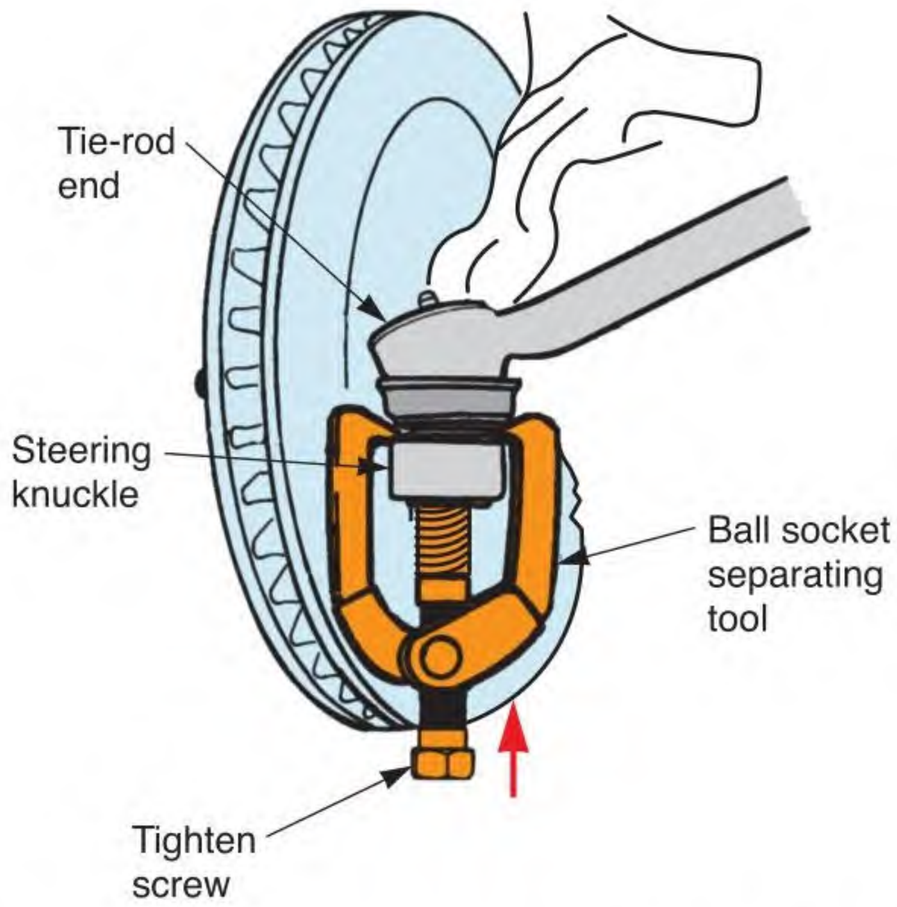
A ***worn idler arm*** is the most common cause of play in the steering wheel. The front wheels, mainly the right wheel, can turn without causing movement of the steering wheel. An idler arm is a very common wear point in a linkage steering system. Check it carefully.

To check an idler arm for wear, grasp the outer end of the arm (the end opposite the frame). Force the idler arm up and down by hand. Note the amount of

Copyright Goodheart-Willcox Co., Inc.

movement at the end of the arm. Compare this movement to specifications. Typically, an idler arm should *not* wiggle up and down more than about 1/4″ (6.5 mm).

A worn idler arm must be replaced. Remove the cotter pin and the castle nut from the outer end of the idler arm. Then, use a fork tool or a puller to force the arm's ball stud out of the hole in the center link. Finally, unbolt the idler arm from the frame.



Install the new idler arm in the reverse order of removal. Make sure you properly torque the idler arm fasteners. Install a new cotter pin and bend it properly.

Tie-Rod Service

A worn tie-rod will also cause steering play. When you detect movement between the ball stud and its socket, install a new tie-rod.

To remove a tie-rod, separate the tie-rod from the steering knuckle or center link. Use a fork or a puller as shown in **Figure 78-6**. Be careful *not* to damage any components.

Before loosening the adjustment sleeve, measure or mark the tie-rod length. This will allow you to set the new tie-rod at about approximately the same length as the old one. The alignment of the front wheels is altered when the length of a tie-rod is changed.

Goodheart-Willcox Publisher

Figure 78-6. A special puller, such as the one shown above, or a fork tool can be used to separate the tie-rod end from the steering knuckle. This tool can also be used on other ball sockets.

Tech Tip

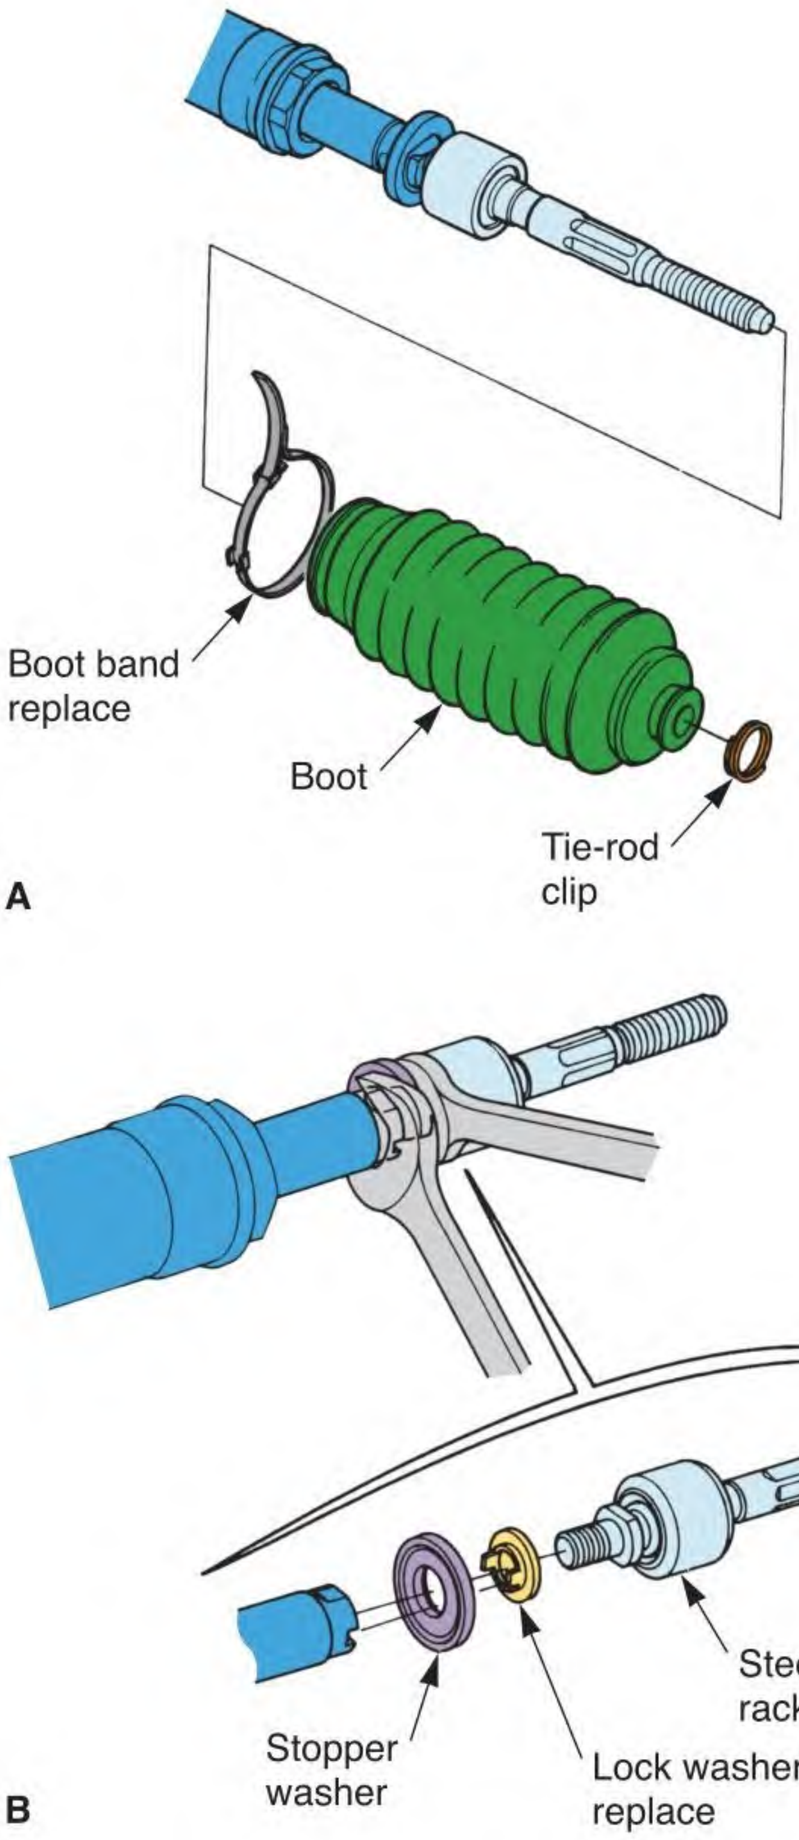
Instead of measuring tie-rod length, you can count the number of turns required to remove the tie-rod from the adjustment sleeve. The new tie-rod end should be installed the same number of turns.

Loosen the tie-rod adjustment sleeve and unscrew the tie-rod end. Turn the new tie-rod end into the sleeve until it is the exact length of the old tie-rod. Install the tie-rod ball stud in the center link or the steering knuckle. Tighten the fasteners to specifications. Install new cotter pins and bend them correctly. Tighten the adjustment sleeve and check steering action. After tie-rod service, always check toe for proper adjustment.

Inner Tie-Rod End Service—Rack-and-Pinion Steering

The service of an inner tie-rod end on a rack-and-pinion assembly is similar to that for a conventional tie-rod end. However, the inner tie-rod end on a rack-and-pinion assembly is enclosed in a rubber boot. Various methods are used to secure the inner tie-rod end.

To remove an inner tie-rod end, remove the boot straps. You usually have to cut them off with side cut pliers. Then, unscrew the inner end of the tie-rod from the rack. See **Figure 78-7**.



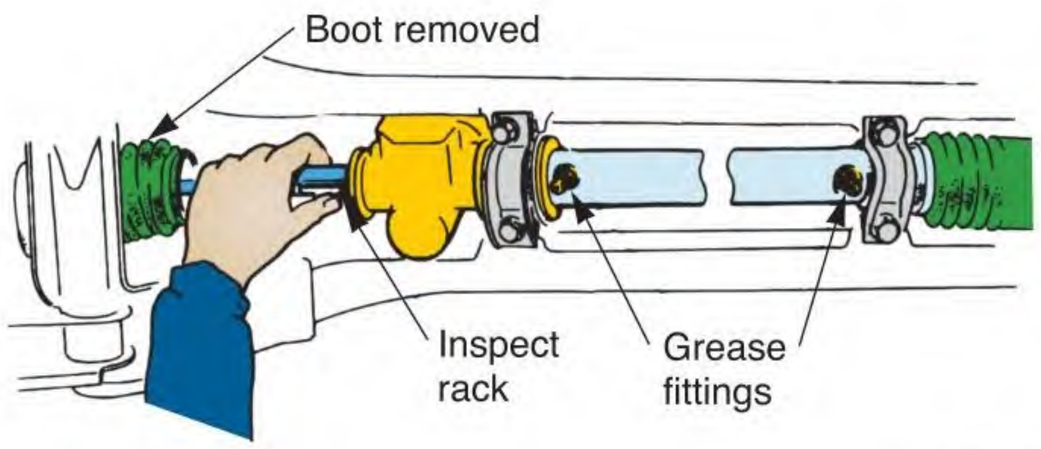
When installing the new inner tie-rod end, install all flat and lock washers in their original locations. Torque the tie-rod nut to factory specs. Replace the boot and boot straps, making sure they are secured into any grooves formed in the tie-rod end and rack.

Manual Rack-and-Pinion Service

A manual rack-and-pinion steering system can develop problems similar to those described for a linkage-type system. However, a rack-and-pinion system has fewer parts to fail. When problems do develop, they are frequently in the tie-rod ends. The rack-and-pinion gear may also wear and cause problems when *not* properly lubricated.

Since so many cars use rack-and-pinion steering, it is important that you learn common service and repair procedures for this type of system.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 78-7. The inner end of the tie-rod on a rack-and-pinion is a common wear point. If wear is not excessive, you may have to remove boot to find play in the inner joint. A—Cut off the old boot straps and slide the boot out of the way. A new boot and straps are normally installed since the boot can rupture after prolonged service. B—Two wrenches are commonly needed to unscrew inner tie-rod end from rack shaft.

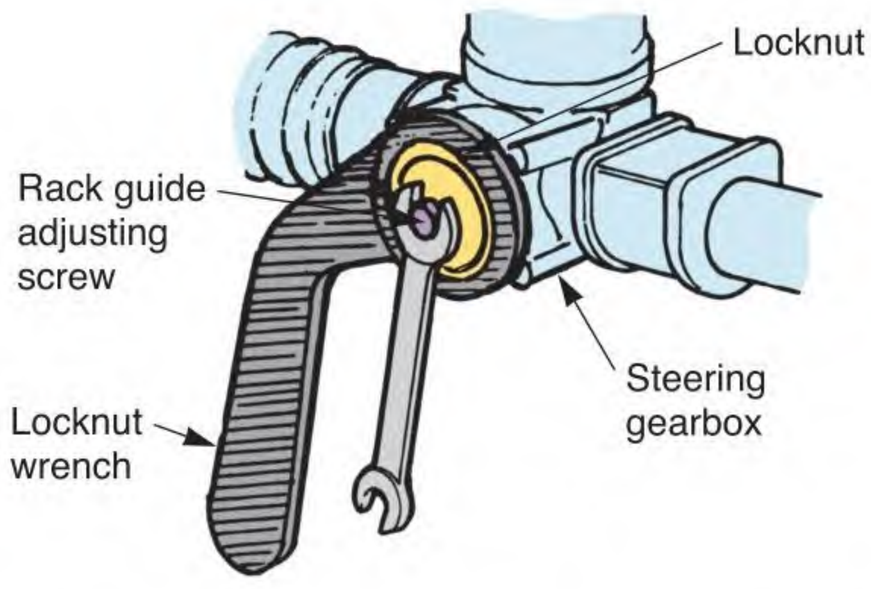
Manual Rack-and-Pinion Lubrication

Some manual rack-and-pinion steering gears require periodic lubrication. See **Figure 78-8**. Others only need lubrication when the unit is torn down for repairs.

A grease gun is used to place chassis grease into the fittings. Use only a small amount of grease, as described by the auto manufacturer.

Honda

Figure 78-8. Many steering system components have grease fittings that require lubrication. In this illustration, the boot has been removed to inspect the inner tie-rod socket.



Manual Rack-and-Pinion Gear Adjustment

Most manual rack-and-pinion steering gears have a rack guide adjustment screw. When there is play in the steering, try adjusting the steering gear, **Figure 78-9**. Follow the manufacturer's directions.

To adjust the rack guide screw, loosen the locknut on the screw. Then, turn the rack guide screw in until it bottoms lightly. Back off the screw the recommended amount (approximately 45%) or until a prescribed turning effort is obtained. Tighten the locknut. Recheck for tight or loose steering and measure steering effort. If not within specs, the steering gear may require major repairs.

Manual Rack-and-Pinion Gear Removal

To remove a manual rack-and-pinion steering gear, separate the outer tie-rods from the steering knuckles. Then, unbolt the steering gear mounting

Honda

Figure 78-9. To adjust the rack guide adjustment screw, hold the locknut while turning the screw. Bottom the adjustment screw and then back it off the prescribed amount.

Copyright Goodheart-Willcox Co., Inc.

brackets from the frame or the crossmember. Disconnect the steering column coupler or universal joint. Rotate the steering gear and slide it out of the chassis, **Figure 78-10**.

Refer to a service manual for additional information. You may have to remove the front wheels or slide the gear out on one particular side of the car.

Manual Rack-and-Pinion Gear Overhaul

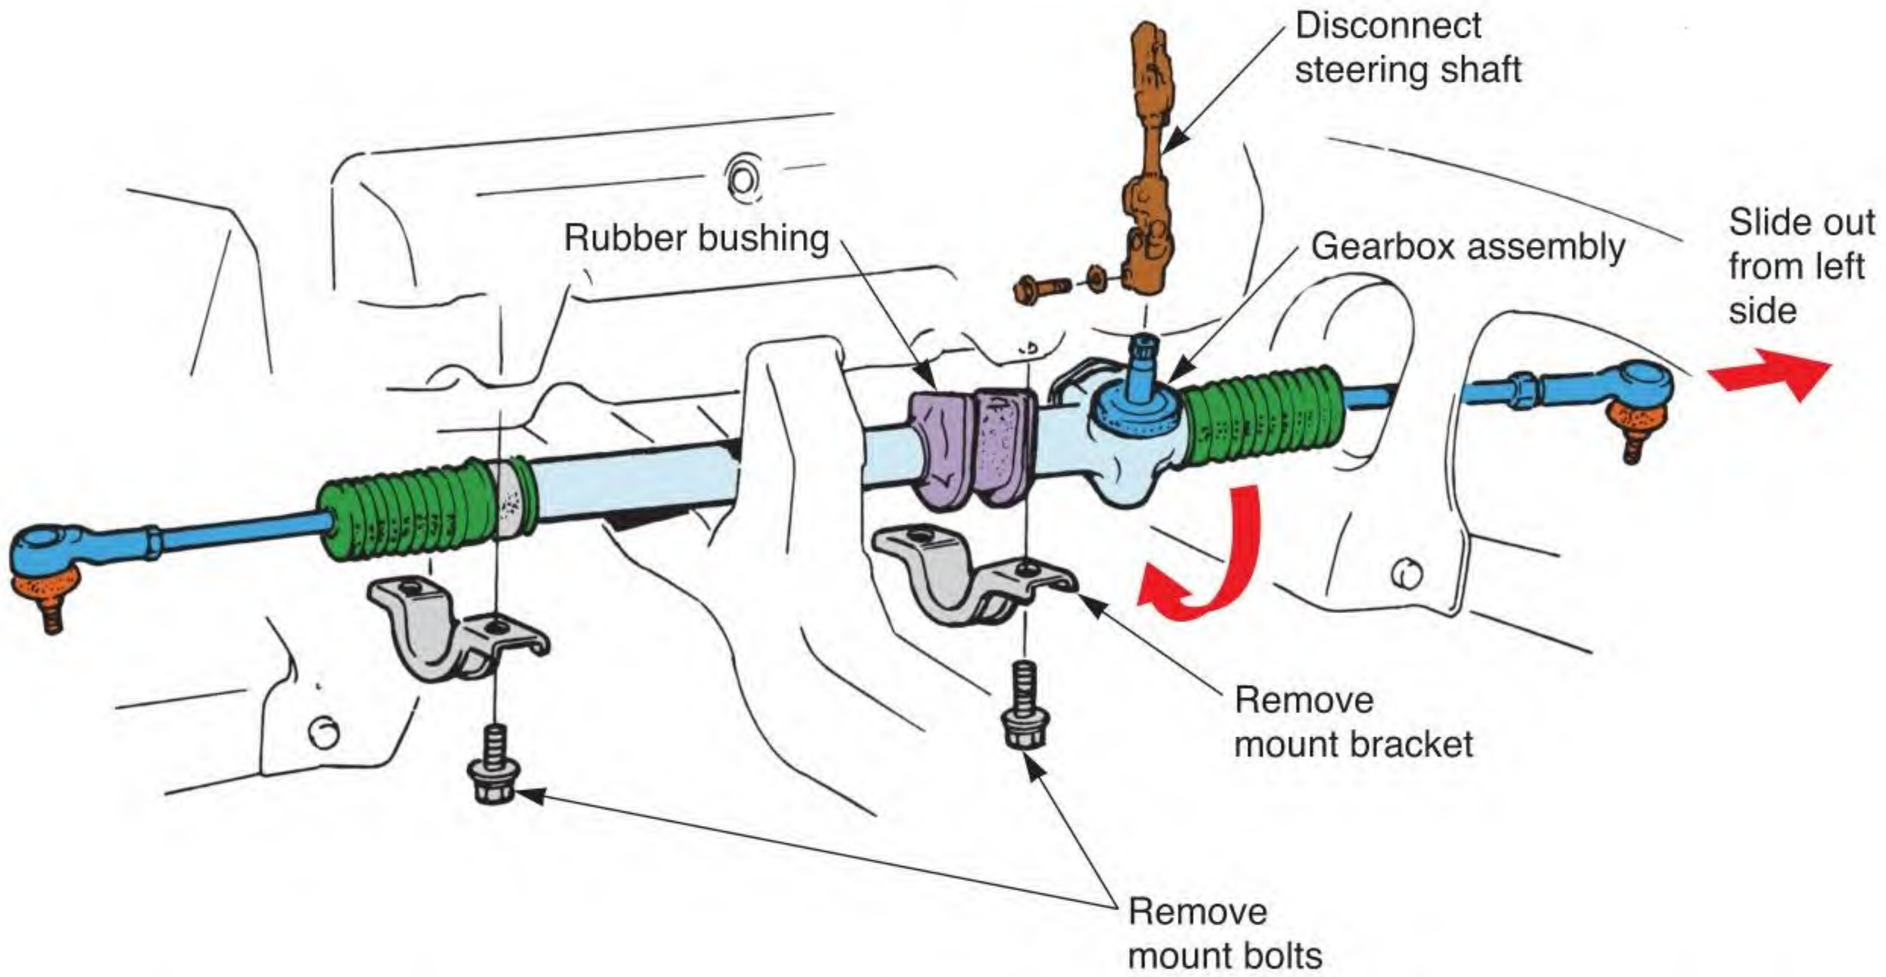
Exact procedures for overhauling a manual rack-and-pinion steering gear will vary with vehicle make and model. Generally, however, you must disassemble the unit and check each part closely. See **Figure 78-11**. Replace any part that shows signs of wear. All seals and other rubber or plastic parts must also be replaced. Use a service manual to obtain the exact procedures for rebuilding a particular unit.

Power Steering System Service

Many of the parts of a power steering system are the same as those used on a manual steering system. However, a pump, power piston, control valve, and hoses are added. These parts can also fail, requiring repair or replacement.

Power Steering Leaks

Power steering fluid leakage is a common problem. With the extremely high pressures produced in power steering systems (over 1000 psi or 6895 kPa), leaks can easily develop around fittings, in hoses, at the gearbox seals, or at the rack-and-pinion assembly. See **Figure 78-12**.

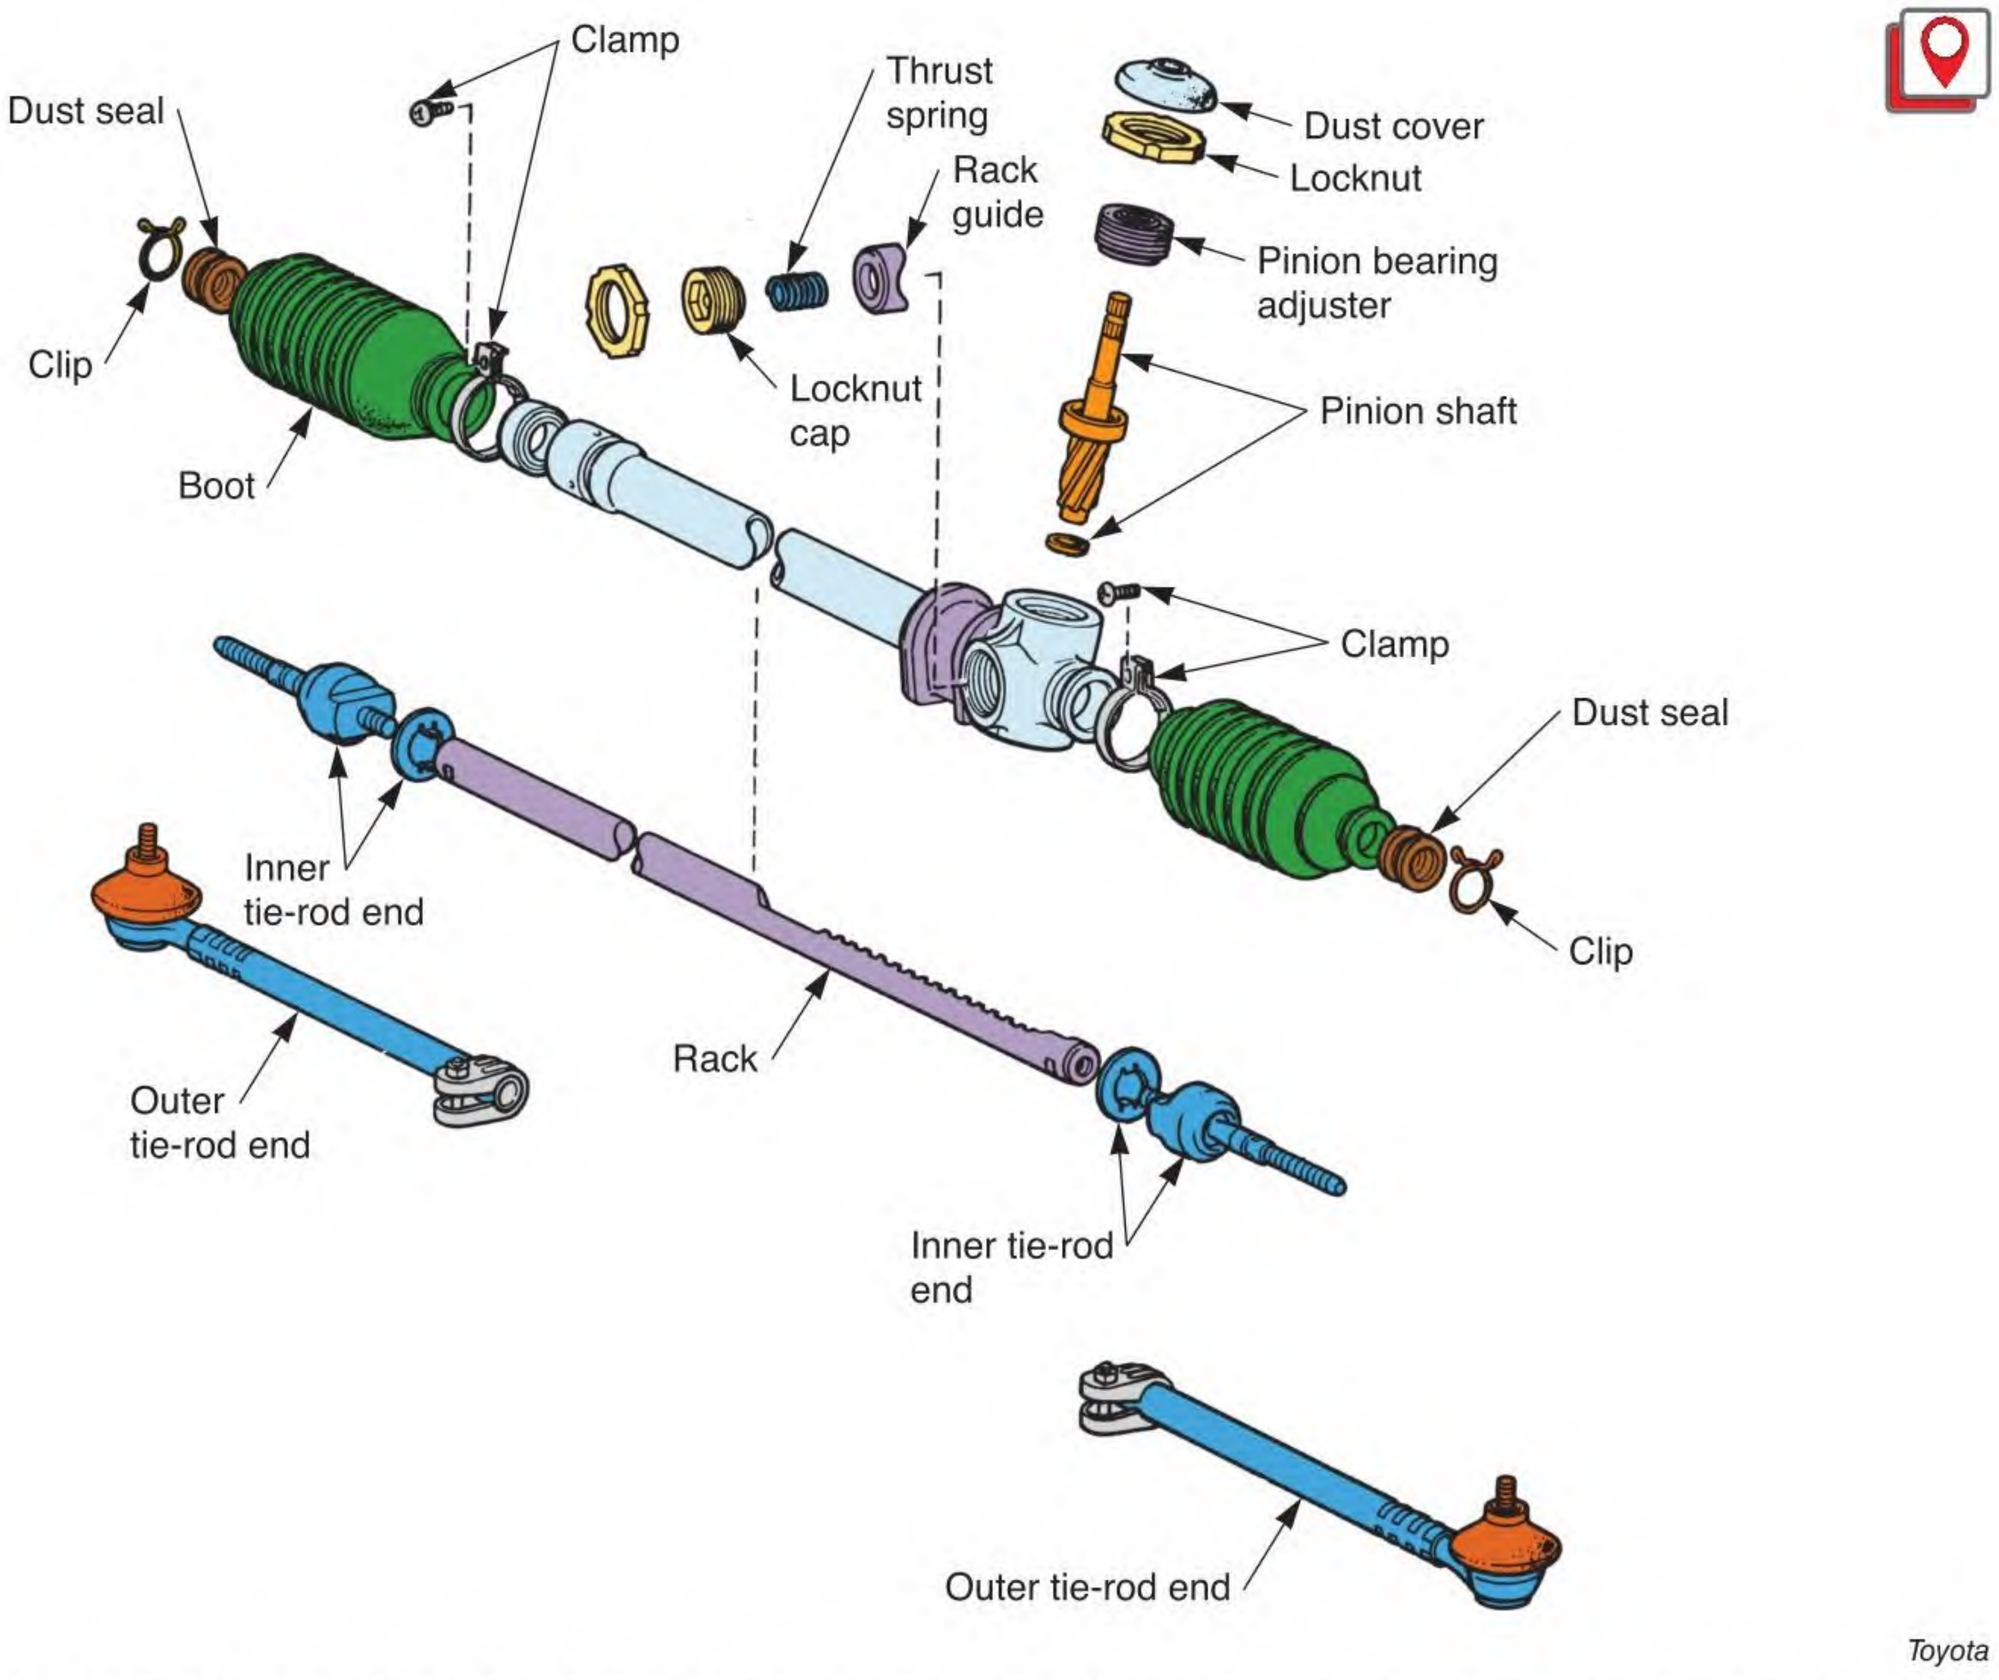


To check for leaks, wipe fluid-soaked areas clean. Then, have a helper start and idle the engine. Watch for leaks as your helper turns the steering wheel to the right and left. Turning the steering wheel pressurizes all parts of the system that might be leaking.

Servicing Power Steering Hoses

Always check the condition of power steering hoses when checking a power steering system. The high-pressure hose can be exposed to tremendous pressures. If this hose ruptures, a sudden and dangerous loss of power assist can occur.

Warning



Power steering pump pressure can exceed 1000 psi (6895 kPa). This is enough pressure to cause a serious eye injury. Wear eye protection when working on a power steering system.

Honda

Figure 78-10. Removal of a rack-and-pinion gear mechanism usually involves disconnecting the parts shown. Slide the unit out one side of the vehicle.

Copyright Goodheart-Willcox Co., Inc.

Toyota

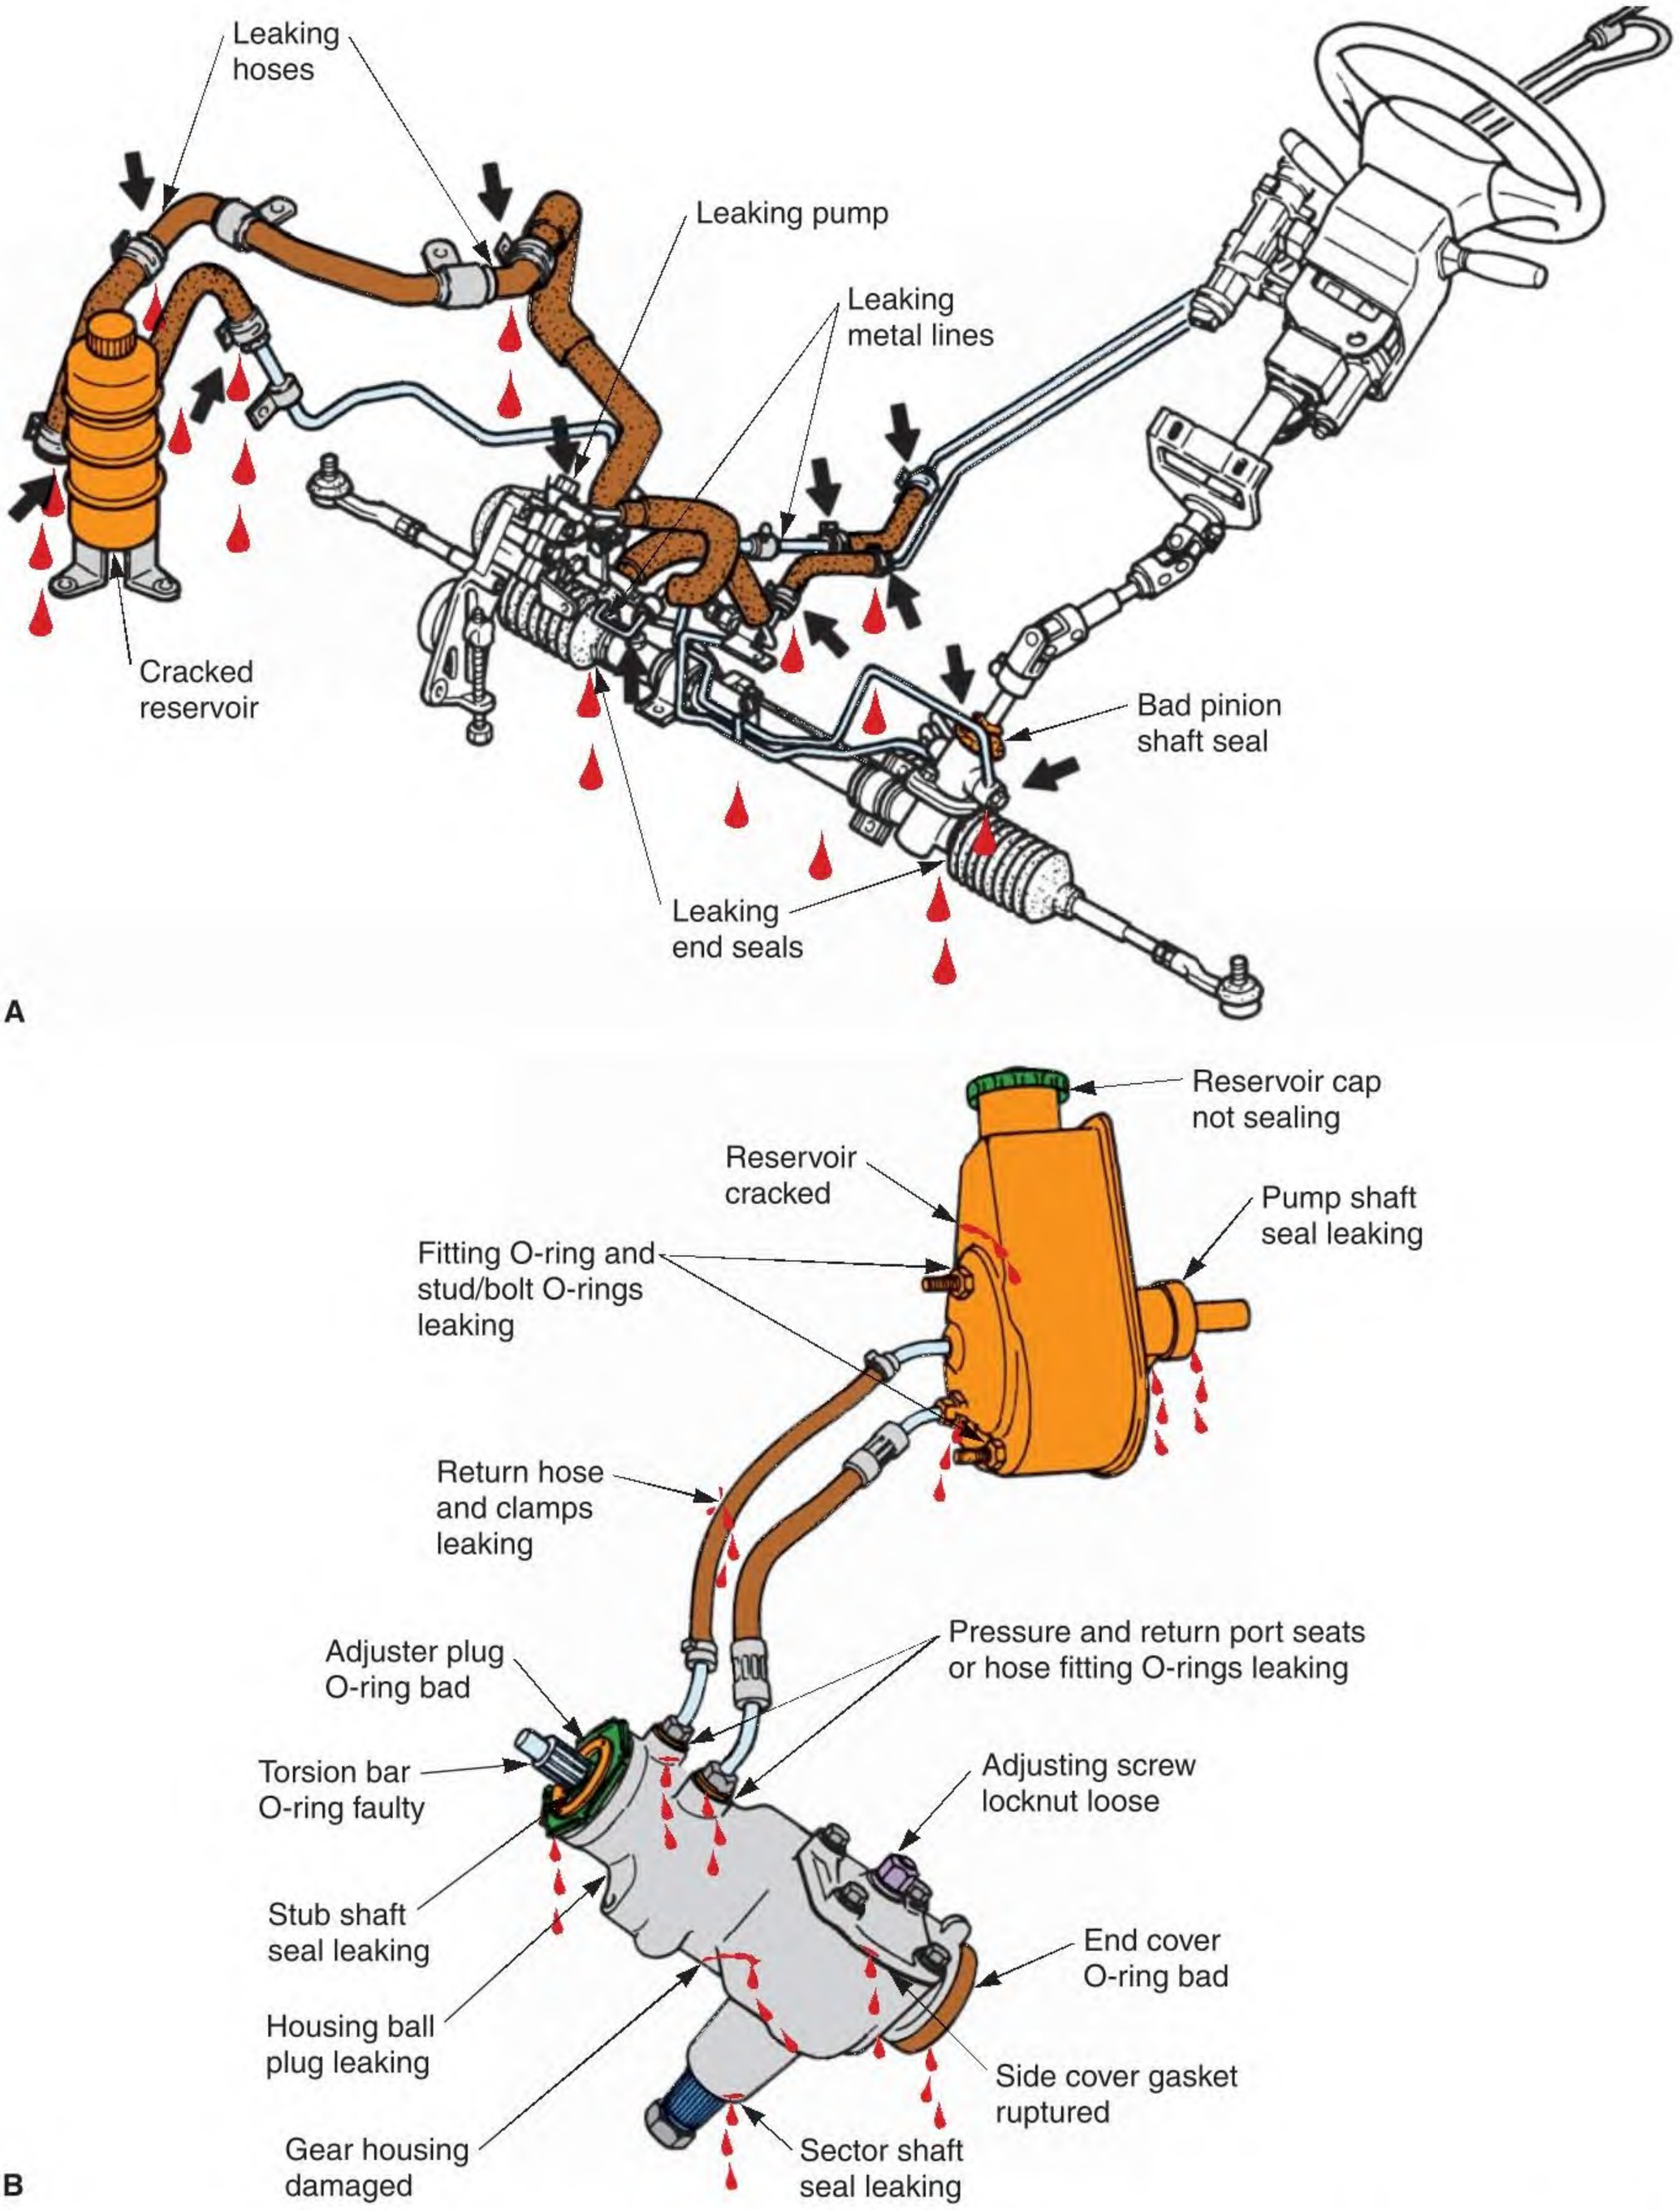
Figure 78-11. Exploded view of typical rack-and-pinion steering mechanism. During service, inspect each component and measure wear.

When installing a new hose, start the new hose fittings by hand to avoid cross threading. Use a tubing wrench to tighten the hose fittings properly. Make sure the hose does *not* contact moving or hot parts. This could cause hose failure.

Power Steering Pressure Test

A ***power steering pressure test*** checks the operation of the power steering pump, pressure relief valve, control valve, hoses, and power piston. Connect a pressure gauge and shutoff valve into the high-pressure hose, as shown in **Figure 78-13**.

When checking power steering system pressure, follow the manufacturer's recommended procedures. Torque the hose fittings properly. Make sure the system is full of fluid. Start the engine and allow it to idle (test valve open) while turning the steering wheel back and forth to bring the fluid up to operating temperature.



To check system pressure, close the test valve. Compare your pressure reading with specifications. When the pressure is *not* within specs, check the condition of the pressure relief valve and the pump.

Caution

Do *not* close the test valve for more than about *five seconds*. If the valve is closed longer, the power steering pump could overheat and be damaged.

To check the action of the power piston, control valve, and hoses, measure system pressure as you turn the steering wheel to full lock (right and left) with

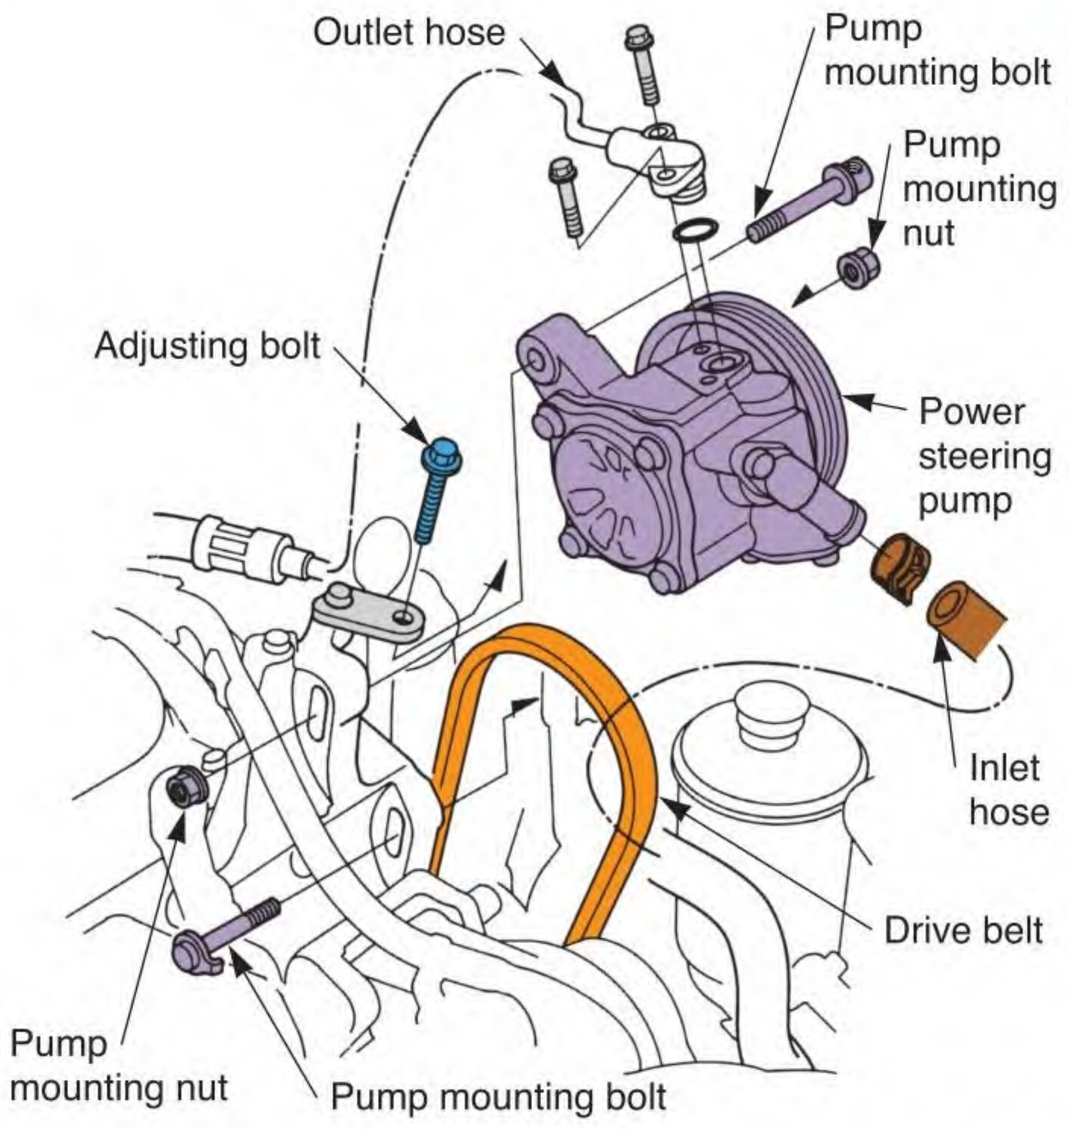

Figure 78-13. The pressure test gauge is connected to the high-pressure hose or line from the pump. Follow service manual instructions when testing a power steering system.

the test valve open. Note the gauge readings and compare them to specs. Use the information in a service manual to determine the source of any trouble.

Power Steering Pump Service

When your tests indicate a bad power steering pump, the pump must be removed for repair or replacement. See **Figure 78-14**. Most shops simply replace a bad power steering pump with a new or factory rebuilt unit. A few shops may disassemble and rebuild the defective pump. Before attempting to rebuild a power steering pump, make sure a rebuild kit is available for the particular unit.

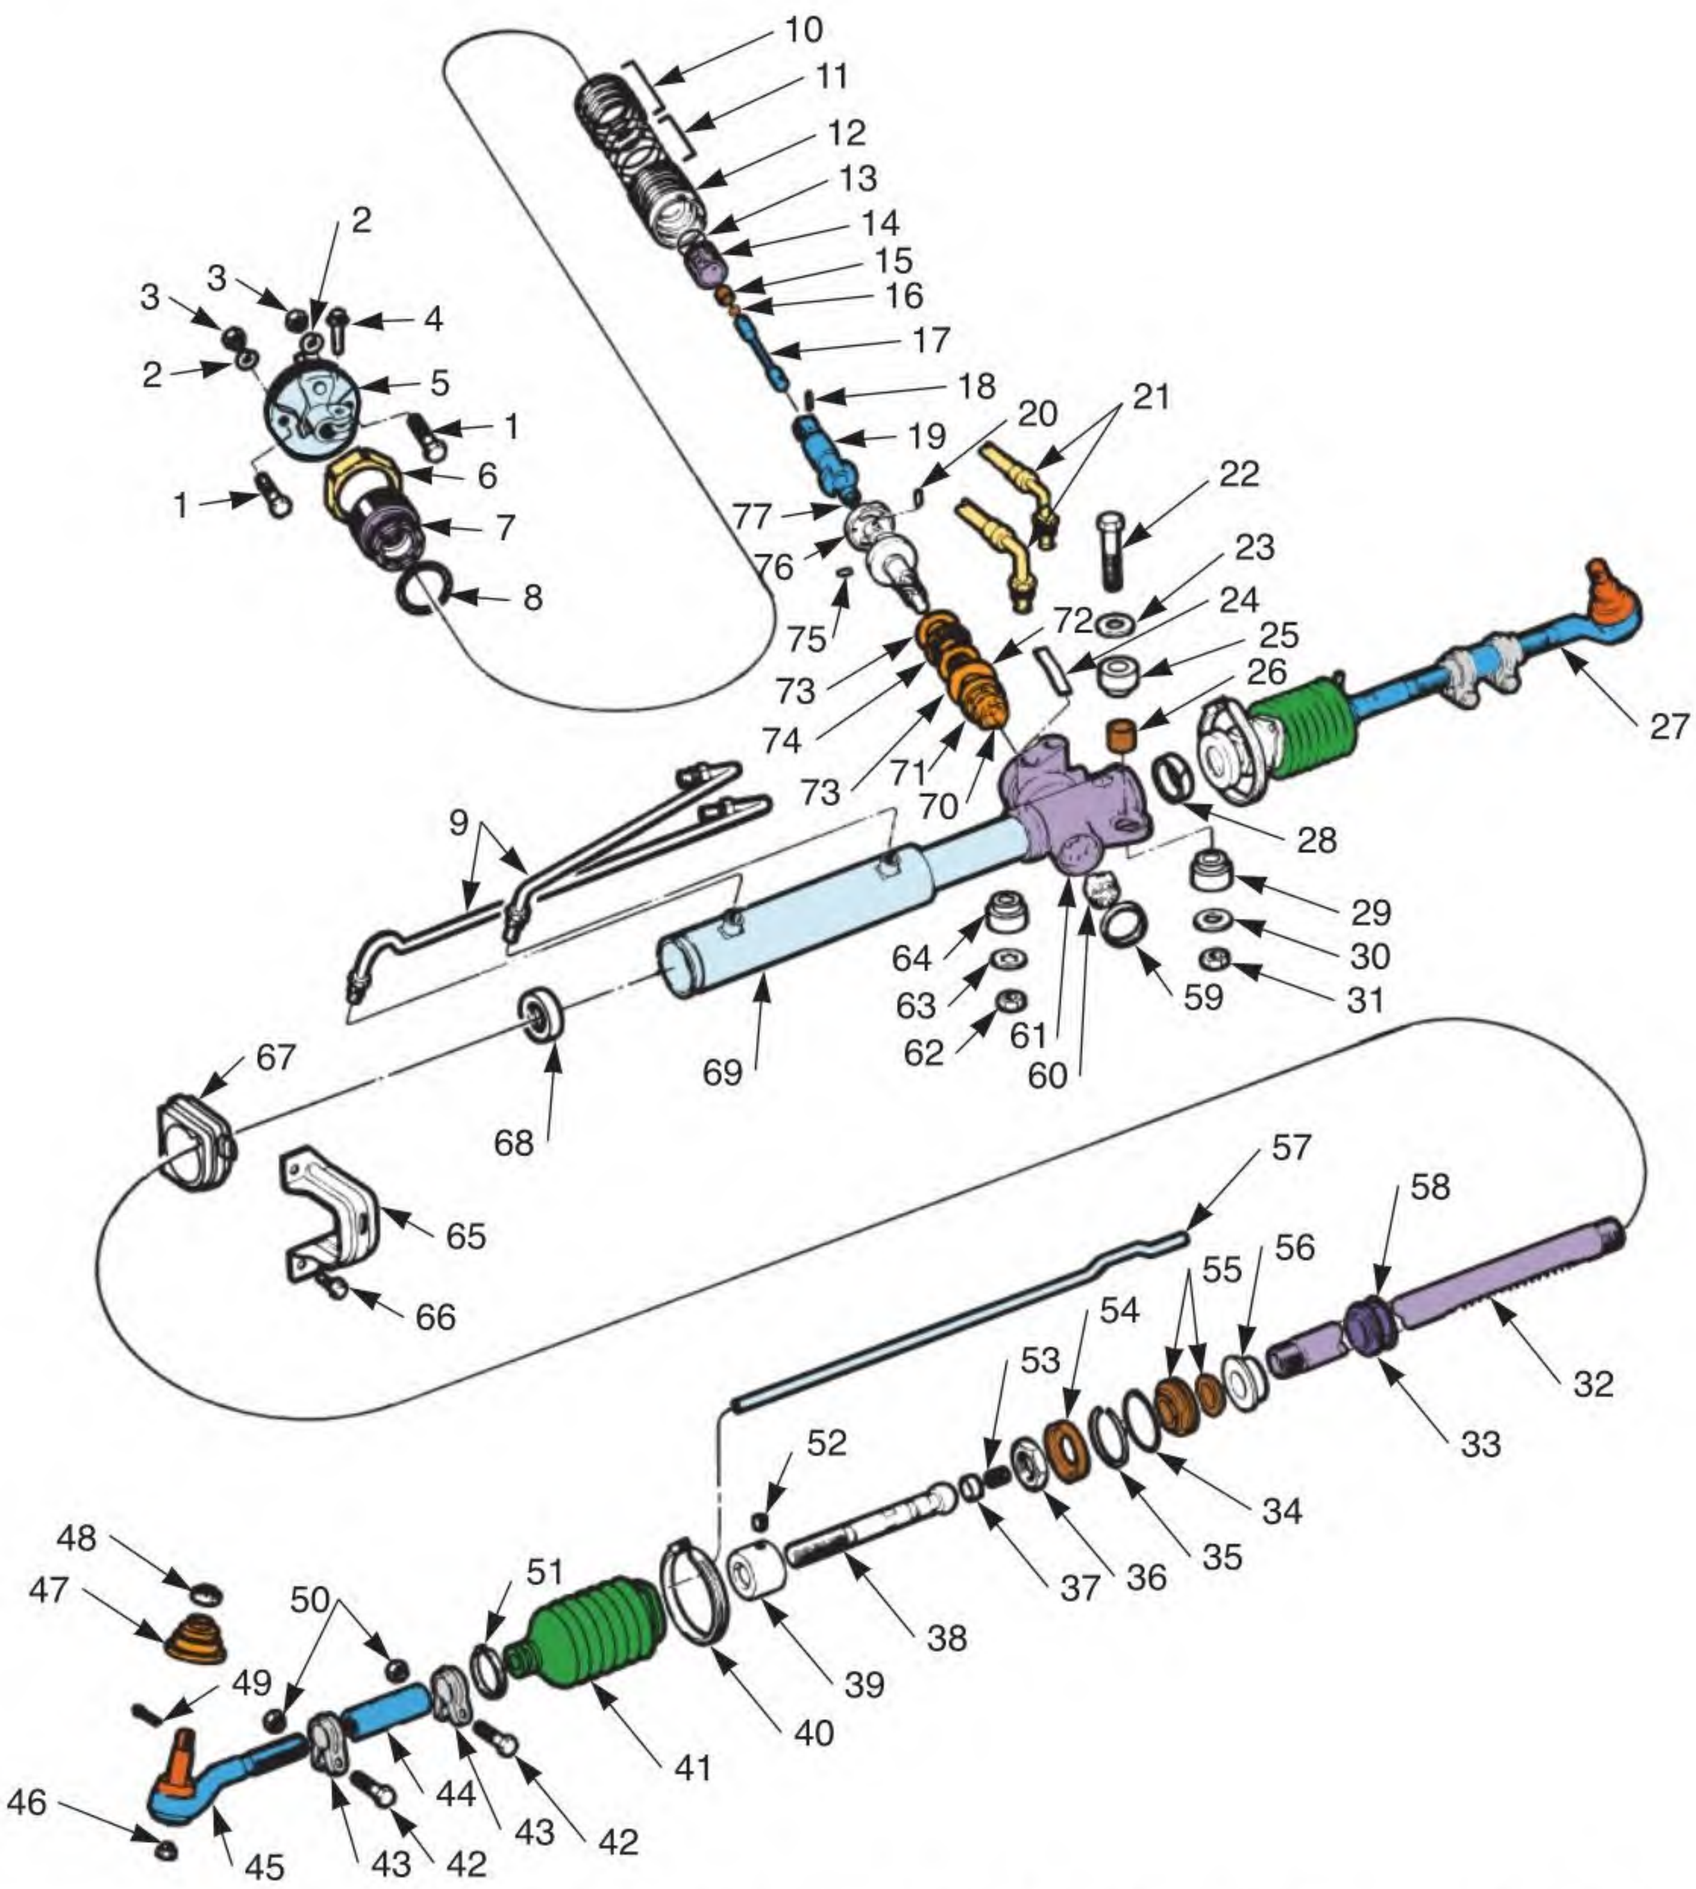
During a pump rebuild, clean and inspect all the parts. In particular, check the pump vanes, thrust plate, and pump ring. Replace all O-rings, gaskets, and seals, as well as any other parts showing signs of wear or damage. Lubricate the parts with the proper fluid before assembly.

Honda

Figure 78-14. Note the bolts, hoses, and brackets that must be removed when replacing a power steering pump.

Power Steering Gear Service

The procedures for servicing power steering gears also vary with the make and model of the vehicle and the type of gear assembly. Follow service manual directions. Note the measurements used to check part wear. Replace all worn parts and every seal, **Figure 78-15**.



Clean and lubricate the parts before reassembly. Use special drivers or pullers to replace worn bushings, if needed. Reassemble the gear assembly according to service manual instructions, **Figure 78-16**.

Bleeding a Power Steering System

When any of the hydraulic components (pump, power piston, hoses) are serviced, you should bleed the power steering system. Bleeding ensures that all air is out of the lines, pump, and gearbox. Air can cause the power steering system to make a buzzing sound. The sound will occur as the steering wheel is turned to the right or left.

To bleed a power steering system, start the engine and turn the steering wheel fully from side to side. Check the fluid level often and add fluid as needed. This forces air into the reservoir and out of the system.

Electronic Assist Steering Service

The service procedures for electronic assist power steering systems are about the same as the procedures described earlier in the text. Since circuit designs vary, you should refer to the shop manual for wiring diagrams, part locations, and electrical values.

Problems with the steering system's electronic circuits will trip diagnostic trouble codes. Your scan tool will let you read operating values in the steering system and quickly isolate the problem area.

A scan tool might show codes for the steering sensor circuit, power steering pump pressure, fluid pressure control solenoid, lateral acceleration sensor, rack motor circuit, and other components or circuits. Use pinpoint tests with a multimeter to verify the source of the problem.

Diagnostic Case Study

Concern: Ms. Love brings in her 2010 Beetle, saying there is too much play in the steering.

Cause: Duff drives the car to verify the problem. Finding excessive play in the steering wheel, he turns the car over to the shop's suspension and steering technician. The technician has a helper wiggle the steering wheel back and forth while she lies on a creeper and checks for play in steering parts. The steering wheel moves almost 2″ (50.8 mm) without movement of wheel and tires.

The technician traces the play to the tie-rod ends. She raises the car on the lift and pushes back and forth on the front tire, revealing play in outer tie-rod ends. The inner tie-rod ends show no signs of wear or play.

Correction: The technician counts the number of threads showing on the tie-rod ends. After removing the cotter pins and nuts, she uses a puller to separate the tie-rod ends from the steering knuckles. She installs new tie-rod ends, making sure the same number of threads are showing so that wheel alignment is not thrown off too much. Finally, she performs a four-wheel alignment, test-drives the vehicle, and releases car to its owner.

Summary

- After prolonged use, the steering system idler arm, gearbox, ball sockets, belts, hoses, and other system parts can wear, causing play in the steering system.
- The dry park test is an effective way to check play in the steering linkage or rack-and-pinion mechanism.
- Hard steering can be caused by problems with the steering gearbox, the rack-and-pinion steering gear, the power steering components, the ball sockets, and the suspension system.
- Steering system noise can be signs of worn parts, unlubricated bearings or ball sockets, loose parts, slipping belts, low power steering fluid, or other system troubles.
- Belt squeal is a loud screeching sound produced by a slipping belt.
- Power steering pump noise is usually a loud whine that occurs when you turn the steering wheel.
- A wheel puller is used to remove a steering wheel from its shaft.
- A worn idler arm from a linkage steering system will cause play in the steering wheel. The front wheels, mainly the right wheel, can turn without causing movement of the steering wheel.
- A worn tie-rod end will cause steering play. When you detect movement between the ball stud and its socket, install a new tie-rod end.
- Most manual rack-and-pinion steering gears have a rack guide adjustment screw. When there is play in the steering, try adjusting the steering gear.
- Exact procedures for overhauling a manual rack-and-pinion steering gear will vary with vehicle make and model.
- Power steering fluid leakage is a common problem.
- Power steering pump pressure can exceed 1000 psi (6895 kPa)—enough pressure to cause serious eye injury.
- A power steering pressure test checks the operation of the power steering pump, pressure relief valve, control valve, hoses, and power piston.
- When tests indicate a bad power steering pump, the pump must be removed for repair or replacement. Most shops simply replace a bad power steering pump with a *new* or factory *rebuilt unit*.
- Bleeding a power steering system ensures that all the air is out of the lines, pump, and gearbox.
- Steering system electrical problems will trip trouble codes that can be read and diagnosed by a scan tool or diagnostic tablet.

Copyright Goodheart-Willcox Co., Inc.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

belt squeal
dry park test
hard steering
power steering pressure test
steering wheel play
wheel puller
worn idler arm

Activities

1. Check the level of power steering lubricant on a vehicle that is in the shop for service.
2. Check a shop manual for lube points, and then lubricate a steering system.
3. Test a steering system and diagnose any problems detected.
4. Prepare a repair bill for a repair to the steering system. Use a flat rate manual to determine time on the job or use an hourly rate set by your instructor. Check a parts catalog for cost of parts.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Excessive steering wheel play is usually shown by turning the steering wheel more than _____ without causing front wheel movement.
   (A) 1 1/2″ (38 mm)
   (B) 3/4″ (19 mm)
   (C) 1/32″ (0.8 mm)
   (D) 1/4″ (6.5 mm)
2. How do you do a "dry park test" of a steering system?
3. A(n) _____ is commonly needed to force a steering wheel off its shaft.
4. Steering system noise can be caused by all of the following problems *except:*
   (A) unlubricated ball sockets.
   (B) broken condenser.
   (C) loose or slipping belt.
   (D) low power steering fluid level.
5. Which of the following components can wear and cause play in the steering system?
   (A) Tie-rod end.
   (B) Idler arm.
   (C) Ball socket.
   (D) All of the above.
6. A(n) _____ system has fewer steering parts to fail compared to a(n) _____ system.
7. Power steering pump pressure can exceed:
   (A) 10,000 psi (68,900 kPa).
   (B) 5000 psi (34,450 kPa).
   (C) 2500 psi (17,236 kPa).
   (D) 1000 psi (6895 kPa).
8. A power steering pressure test checks the operation of the pump, relief valve, control valve, hoses, and power piston. True or False?
9. Most technicians install rebuilt or new power steering pumps rather than overhauling the defective unit in the shop. True or False?
10. After hydraulic steering components have been serviced, the system should be _____.

ASE-Type Questions

1. A car is brought into the shop with excessive steering wheel play. Technician A checks for worn ball sockets. Technician B checks the condition of the system's idler arm. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. A car's steering wheel turns three inches before causing movement of the front wheels. Technician A tells the owner of the vehicle that this indicates normal play in the steering system. Technician B tells the owner of the vehicle that this indicates excessive steering wheel play. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Lubricant is leaking from a car's power steering system. Technician A says that, if equipped, a dipstick attached to the reservoir cap can be used to measure power steering fluid level. Technician B says that a cracked reservoir could be the source of the leakage. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

4. An automobile has a "hard steering" problem. Technician A checks the steering gearbox for problems. Technician B inspects the suspension system for problems. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Noise is coming from a steering pump. Technician A checks the inner tie-rod ends. Technician B checks the pump's fluid level. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. An automotive power steering system's fluid level needs to be checked. Technician A checks the steering system's fluid level with the engine off. Technician B checks the fluid level while the engine is running. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says the alignment of the front wheels is changed when a tie-rod is changed. Technician B says that during steering wheel and air bag removal, it is recommended to keep the vehicle battery connected. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. A car's power steering belt is loose. Technician A says the belt may be worn and stretched and might require replacement. Technician B says the belt tensioner may be broken and unable to apply enough tension to the belt. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. An automobile's steering column needs servicing. Technician A tells the owner of the car that most steering columns can be repaired with the column mounted in the car. Technician B tells the owner of the car that most steering columns must be removed from the vehicle when service is required. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. A car's steering wheel needs to be removed from its shaft. Technician A uses a hammer and brass punch to perform this service procedure. Technician B uses a wheel puller to perform this service procedure. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. Technician A says that power steering systems are not susceptible to "hard steering" problems. Technician B says that accurately diagnosing an electronic assist steering system requires a scan tool or diagnostic tablet. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. A car equipped with manual rack-and-pinion steering is brought into the shop with excessive steering wheel play. Technician A adjusts the steering gear. Technician B adjusts the idler arm. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. An automobile's power steering pump is not operating properly. Technician A performs a power steering pressure test to check the operation of the power steering pump. Technician B says a power steering pressure test will not detect power steering pump malfunctions. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. A "buzzing" sound is coming from an automobile's power steering system when the wheel is turned. Technician A tells the owner of the vehicle that this problem may be the result of a damaged pitman arm. Technician B tells the owner of the vehicle that this problem may be caused by air in the power steering system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

Manual and Power Steering Systems Diagnosis

Condition	Possible Causes	Correction
Hard steering and poor recovery following turns.	1. Low tire pressure. 2. Defective power steering pump. 3. Power steering pump fluid level low. 4. Manual steering gear lubricant level low. 5. Incorrect front wheel alignment. 6. Dry ball joints. 7. Dry steering linkage sockets. 8. Binding linkage. 9. Damaged suspension arms. 10. Steering gear adjusted too tight. 11. Dry steering shaft bushing. 12. Binding steering shaft bushing or coupling. 13. Excessive caster. 14. Sagged front springs. 15. Bent spindle body. 16. Steering wheel rubbing steering column jacket. 17. Misaligned steering gear. 18. Sticky valve spool. 19. Loose steering pump belt. 20. Kinked or clogged power steering hose. 21. Different size front tires. 22. Malfunctioning steering gear pressure port poppet valve. 23. Maladjusted rack-and-pinion. 24. High internal leakage of rack-and-pinion assembly. 25. Rack-and-pinion mountings loose, causing binding. 26. Defective steering stabilizer.	1. Inflate to correct pressure. 2. Repair or replace pump. 3. Add fluid to reservoir. 4. Add lubricant. 5. Align front wheels. 6. Lubricate ball joints. 7. Lubricate linkage. 8. Relieve binding. 9. Replace arms. 10. Adjust gear correctly. 11. Lubricate bushings. 12. Align shaft or coupling. 13. Adjust caster. 14. Replace springs. 15. Replace spindle. 16. Adjust jacket; check for steering shaft damage. 17. Align gear. 18. Clean or replace spool valve. 19. Adjust belt tension. 20. Replace hose. 21. Install correct size tires on both sides. 22. Repair or replace. 23. Adjust to specifications. 24. Repair leaks or replace gear. 25. Tighten mountings to specifications. 26. Replace stabilizer.
Vehicle pulls to one side.	1. Uneven tire pressure. 2. Brakes dragging. 3. Improper front end alignment. 4. Improperly adjusted wheel bearings. 5. Damaged or worn steering valve assembly. 6. Tire sizes not uniform. 7. Broken or sagging spring. 8. Misaligned rear axle housing. 9. Bent spindle. 10. Frame sprung. 11. Radial tire problem.	1. Equalize pressure. 2. Adjust brakes. 3. Align front end. 4. Adjust bearings. 5. Replace steering valve assembly. 6. Install tires of the same size. 7. Replace spring. 8. Align rear housing. 9. Replace spindle. 10. Straighten frame. 11. Switch front tires. If vehicle now pulls in the other direction, tires are defective.

Manual and Power Steering Systems Diagnosis

Condition	Possible Causes	Correction
Vehicle wanders from side to side.	1. Weak shock absorber or strut. 2. Loose steering gear. 3. Loose rack-and-pinion mountings. 4. Ball joints and steering linkage need lubrication. 5. Steering gear not on high point. 6. Broken or missing stabilizer bar or link. 7. Improperly adjusted rack-and-pinion. 8. Loose tie-rod end.	1. Replace shocks or struts. 2. Torque mounting fasteners. 3. Tighten to specifications. 4. Lubricate suspension. 5. Adjust steering gear properly. 6. Replace stabilizer or link. 7. Adjust to specifications. 8. Tighten. Replace if worn.
Sudden increase in steering wheel resistance.	1. Slipping pump belt. 2. Internal leakage in gear. 3. Fluid level low in pump. 4. Low engine idle. 5. Air in system. 6. Low tire air pressure. 7. Insufficient pump pressure. 8. High internal leakage in rack-and-pinion. 9. Defective steering stabilizer.	1. Adjust belt tension. 2. Overhaul or replace gear. 3. Add fluid. 4. Adjust idle. 5. Bleed system. 6. Inflate to recommended level. 7. Test and repair or replace as required. 8. Repair leaks or replace gear. 9. Replace stabilizer.
Steering wheel action jerky during parking.	1. Loose pump belt. 2. Oily pump belt. 3. Defective flow control valve. 4. Insufficient pump pressure.	1. Adjust belt tension. 2. Replace belt. Clean pulleys. Repair source of leak. 3. Replace flow control valve. 4. Test and repair.
No effort required to turn steering wheel.	1. Broken steering gear torsion bar. 2. Broken tilt column U-joint. 3. Missing steering wheel hub-to-shaft key. Stripped splines. Loose nut.	1. Replace spool valve and shaft assembly. 2. Replace U-joint. 3. Replace key, shaft, or wheel. Tighten nut to specifications.
Excessive wheel kickback and play.	1. Worn steering linkage. 2. Air in system. 3. Improperly adjusted front wheel bearings. 4. Loose gear over-center adjustment. 5. Worm gear not preloaded. 6. No worm to rack-piston preload. 7. Loose pitman arm. 8. Loose steering gear. 9. Steering arms loose on spindle body. 10. Excessive play in ball joints. 11. Defective rotary valve. 12. Worn steering shaft universal joint. 13. Extra large tires. 14. Defective steering stabilizer.	1. Replace worn linkage components. 2. Bleed and add fluid if needed. 3. Adjust front wheel bearings. 4. Make correct over-center adjustment. 5. Preload worm gear. 6. Install larger set of rack-piston balls. 7. Torque pitman arm nut. 8. Tighten mounting fasteners. 9. Tighten arm fasteners. 10. Replace ball joints. 11. Replace rotary valve. 12. Replace joint and/or shaft. 13. Advise owner. Install a steering stabilizer or replace with a larger stabilizer. 14. Replace stabilizer.
No power assist in one direction.	1. Defective steering gear.	1. Overhaul or replace gear as needed.

Chapter 79
Wheel Alignment

After studying this chapter, you will be able to:

- Explain the principles of wheel alignment.
- List the purpose of each wheel alignment setting.
- Explain toe-out on turns, steering axis inclination, and tracking.
- Perform a prealignment inspection of tires, steering, and suspension systems.
- Describe caster, camber, and toe adjustment.
- Describe the use of different types of wheel alignment equipment.
- Correctly answer ASE certification test questions about wheel alignment angles and procedures.

The term ***alignment*** means "to position in a straight line." Relating to passenger vehicles, wheel alignment means to adjust the suspension geometry so that all four tires roll in a straight line with full tread contact on the road surface.

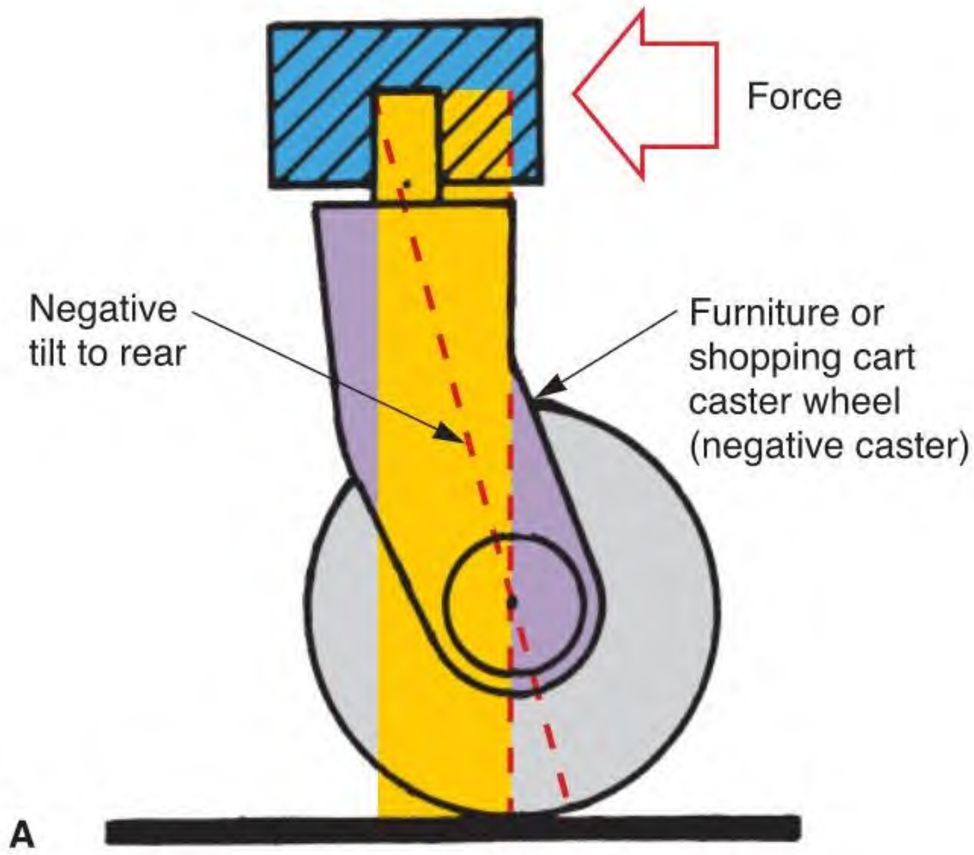
Correct wheel alignment is essential to automobile safety, sure handling, maximum fuel economy, and long tire life. This chapter introduces both the principles and the basic procedures for wheel alignment.

Tech Tip

For a complete understanding of the information in this chapter, you should have studied the previous chapters on wheel bearings, suspension systems, and steering systems. These systems must be in good condition before attempting wheel alignment.

Wheel Alignment Principles

The main purpose of ***wheel alignment*** is to make the tires roll without scuffing, slipping, or dragging under all operating conditions. Six fundamental angles or specifications are needed for proper wheel alignment:



- Caster.
- Camber.
- Toe.
- Steering axis inclination.
- Toe-out on turns (turning radius).
- Tracking (thrust line).

Copyright Goodheart-Willcox Co., Inc.

Caster

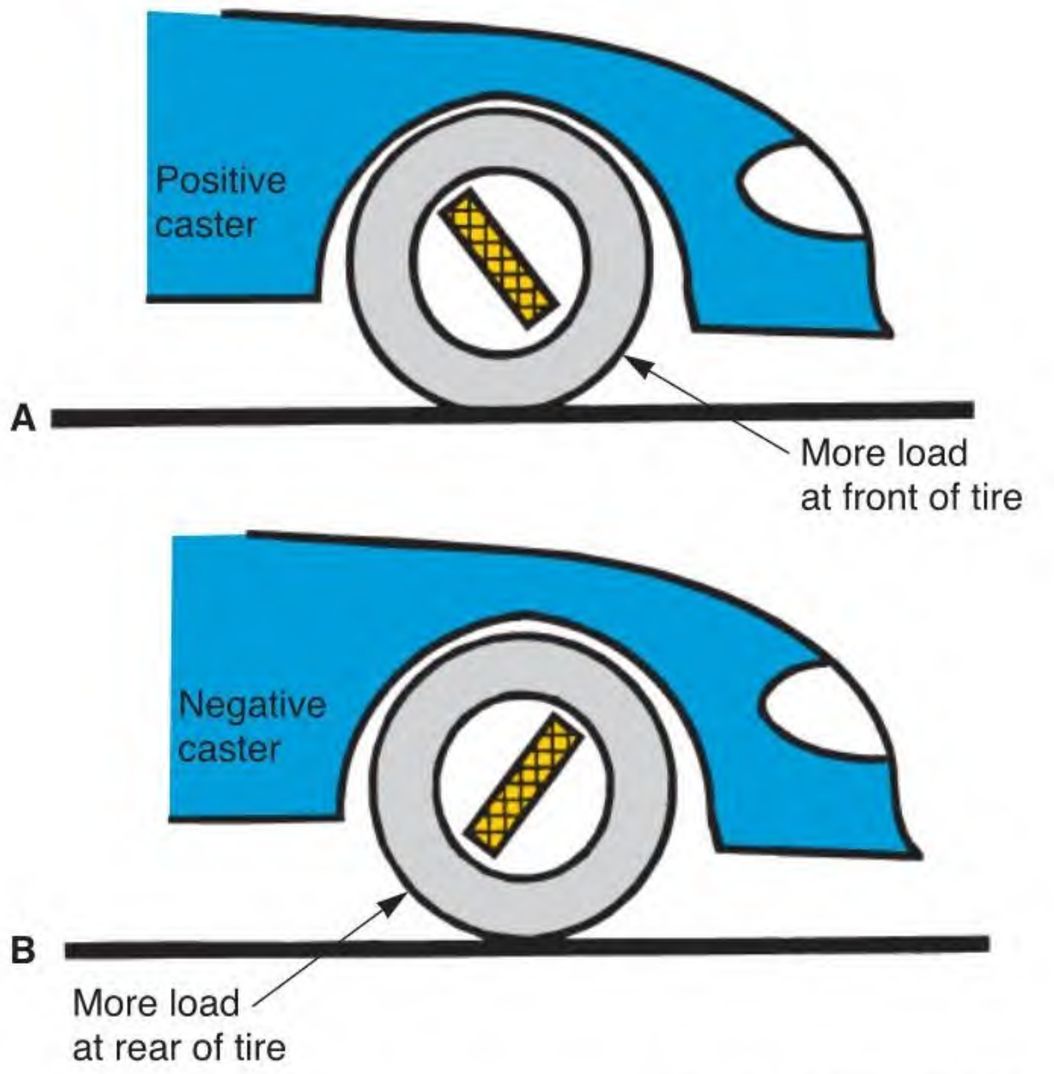
Caster is basically the forward or rearward tilt of the steering knuckle (spindle support) when viewed from the side of the vehicle. You are probably familiar with the term *caster* from furniture casters. See **Figure 79-1**.

Caster controls the tire's load distribution in relation to an imaginary centerline drawn through the spindle support. It is *not* a tire wearing angle, but a directional stability angle.

Goodheart-Willcox Publisher

Figure 79-1. Caster is determined by the contact point of the tire and an imaginary centerline through the spindle support. A—Negative caster of ball joints is illustrated by a shopping cart wheel. The wheel follows the irregular surfaces in the floor. B—Positive caster, like that on a front bike tire, makes the front wheel travel straight ahead.

The basic purposes of caster are:

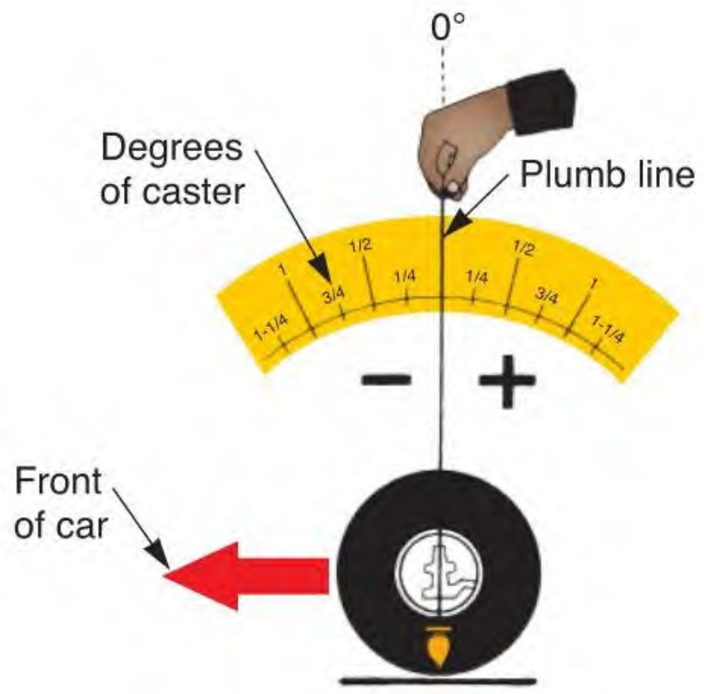


- To aid directional control of the vehicle.
- To cause the wheels to return to the straight-ahead position.
- To offset ***road crown pull*** (steering wheel pull caused by hump in center of road).

Positive caster tilts the top of the steering knuckle toward the rear of the vehicle. Positive caster helps keep the vehicle's wheels traveling in a straight line. When you turn the wheels, it lifts the vehicle. Since this takes extra turning force, the wheels resist turning and try to return to the straight-ahead position. See **Figure 79-2A**.

Negative caster tilts the top of the steering knuckle toward the front of the vehicle. It is the opposite of positive caster. With negative caster, the wheels will be easier to turn. However, the wheels will tend to swivel and follow imperfections in the road. Look at **Figure 79-2B**.

Caster is measured in *degrees*, starting at the true vertical (plumb line). Auto manufacturer's give specs for caster as a specific number of degrees positive or negative. This is illustrated in **Figure 79-3**.



Typically, positive caster is recommended for vehicles with power steering. To ease steering effort,

Goodheart-Willcox Publisher

Figure 79-2. A—Positive caster tilts the steering knuckle toward the rear of the vehicle. B—Negative caster tilts the steering knuckle toward the front of the vehicle.

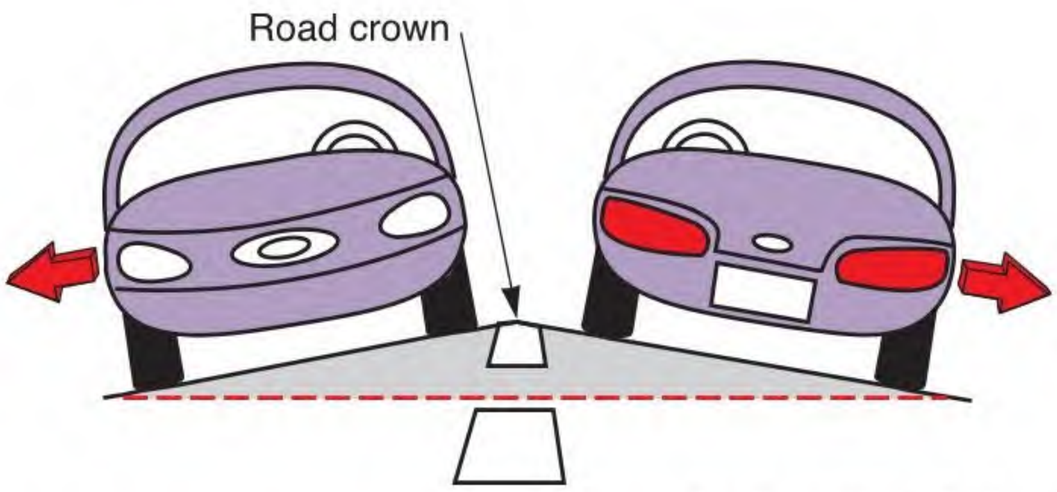
Bear

Figure 79-3. Caster is measured in degrees, as shown.

negative caster is recommended for vehicles with manual steering.



Caster and Road Crown Effect

Caster is a *directional control* angle. It determines whether the vehicle travels straight or pulls (steering wheel tries to turn) to the right or left.

Road crown is the normal slope toward the outer edge of the road surface. Most road surfaces angle downward from the center. This helps keep rainwater from collecting on the pavement.

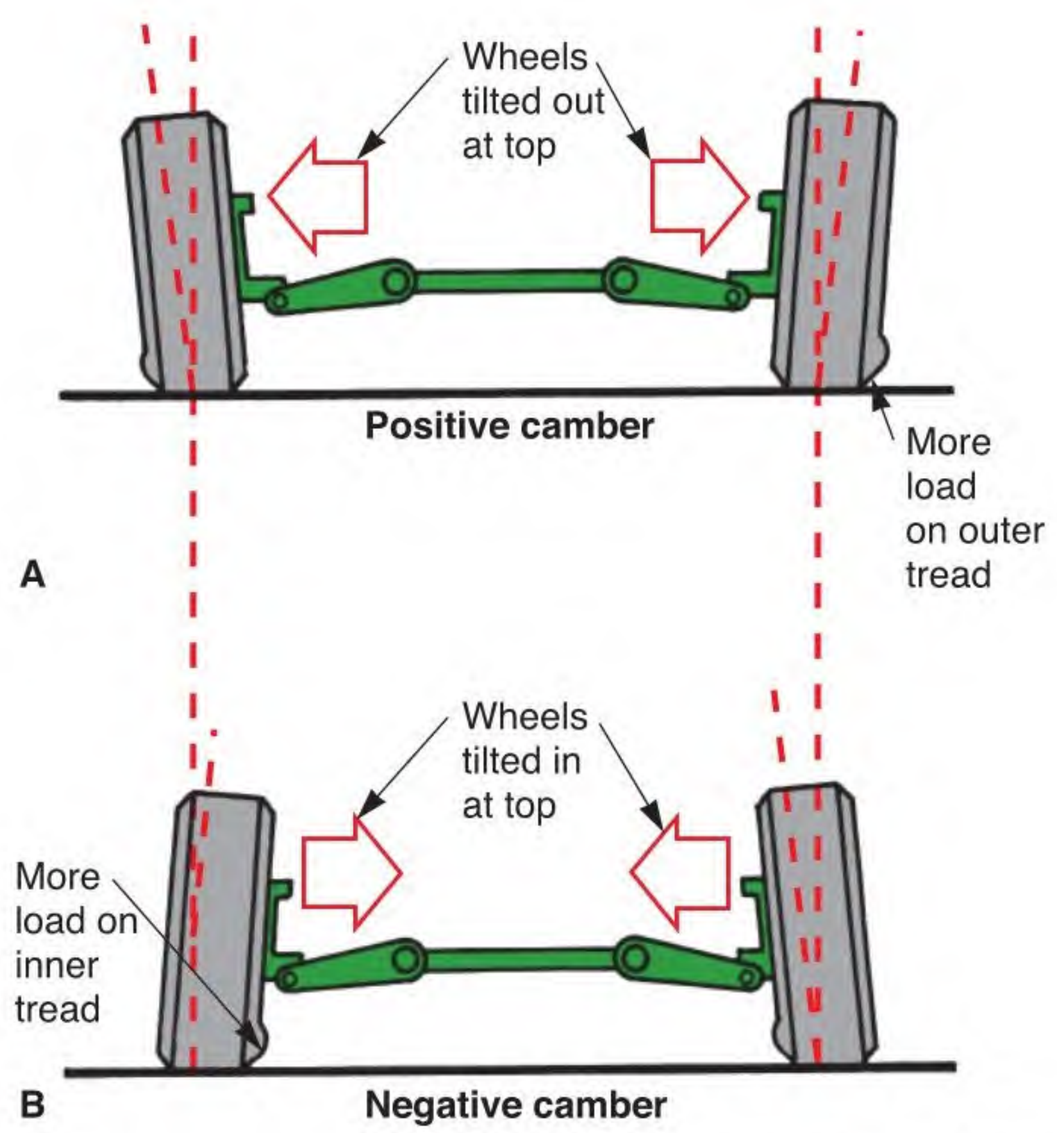
If the caster of both front wheels were the same, the road crown could make the vehicle pull or steer toward the outside (lower) edge of the road, **Figure 79-4**.

Since caster is a directional control angle, it is commonly used to offset the effect of road crown. The right front wheel may be set with slightly more positive caster than the left. This counteracts the forces caused by the road crown, and the vehicle will travel straight ahead.

Goodheart-Willcox Publisher

Figure 79-4. Most roads are crowned in the center to help water flow off the surface. Unequal caster can be used to offset road crown and keep the vehicle from trying to steer off the road.

Camber

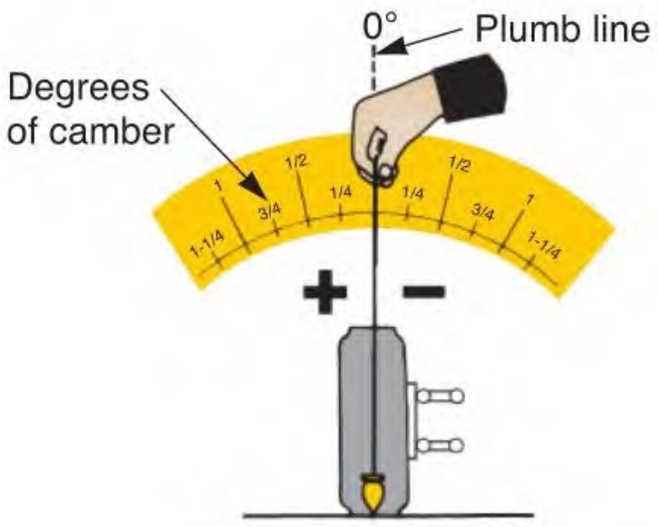


Camber is the inward or outward tilt of the wheel and tire assembly when viewed from the front of the vehicle. It controls whether the tire tread touches the road surface evenly. Camber is a tire-wearing angle and is measured in degrees. Refer to **Figure 79-5**.

There are three reasons for camber:

- To prevent tire wear on the outer or inner tread.
- To load the larger inner wheel bearing.
- To aid steering by placing vehicle weight on the inner end of the spindle.

With ***positive camber***, the tops of the wheels tilt outward when viewed from the front of the vehicle, **Figure 79-5A**. With ***negative camber***, the tops of the wheels tilt inward when viewed from the front. Refer to **Figure 79-5B**.



Negative and positive camber are measured from the true vertical (plumb line). If the wheel is aligned with the plumb line, camber is zero, **Figure 79-6**.

Goodheart-Willcox Publisher

Figure 79-5. Camber is determined by the inward or outward tilt of the wheels when viewed from the front of a vehicle. Positive camber has the wheels tilted out at the top. Negative camber has the wheels tilted out at the bottom.

Copyright Goodheart-Willcox Co., Inc.

Bear

Figure 79-6. Camber is measured in degrees, as shown.

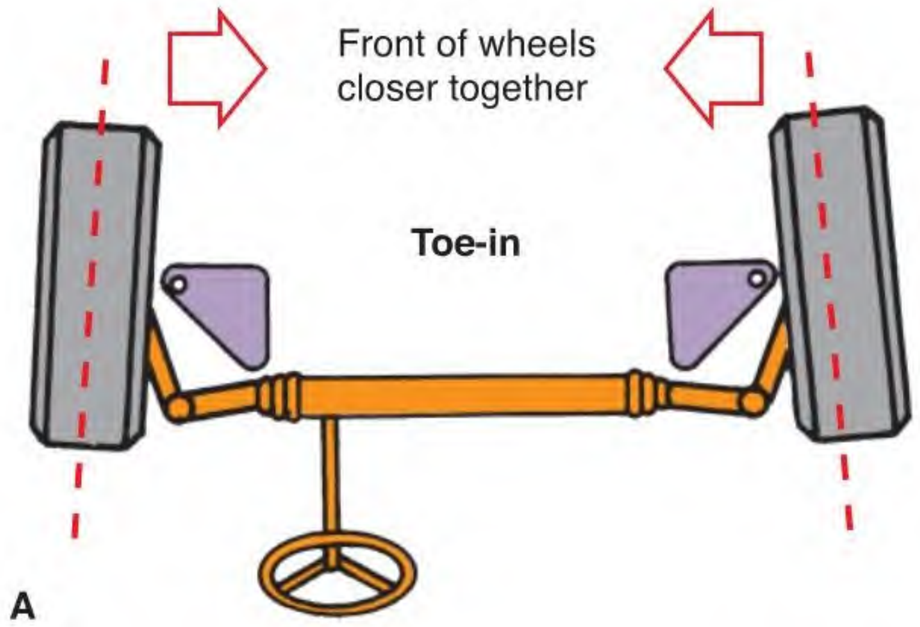
Camber Settings

Most vehicle manufacturers suggest a slight positive camber setting (about 1/4° to 1/2°). Suspension wear and above-normal weight, caused by several passengers or extra luggage, tend to increase negative camber. Positive camber counteracts this tendency.

Toe

Toe is determined by the difference in distance between the front and rear of the left- and right-hand wheels. Look at **Figure 79-7**.

Measured in inches or millimeters, toe controls whether the wheels roll in the direction of travel. Toe is very critical to *tire wear*. If the wheels do *not* have the correct toe setting, the tires will scuff, or skid sideways.



Toe-in is produced when the wheels are closer at the front than at the rear. Toe-in causes the wheels to point inward at the front, **Figure 79-7A**.

Toe-out results when the wheels are farther apart at the front than at the rear. Toe-out causes the front of the wheels to point away from each other. See **Figure 79-7B**.

Front-wheel-drive and rear-wheel-drive vehicles normally require much different toe settings. This is because the front-wheel drive tends to pull the front tires forward. With rear-wheel-drive vehicles, rolling resistance tends to push the front tires backward.

Rear-Wheel-Drive Toe Settings

Rear-wheel-drive vehicles are usually set to have *toe-in* at the front wheels. This is because the front wheels tend to toe-out while driving. Toe-in is needed to compensate for the action of tire rolling resistance, play in the steering system, and suspension system action.

Goodheart-Willcox Publisher

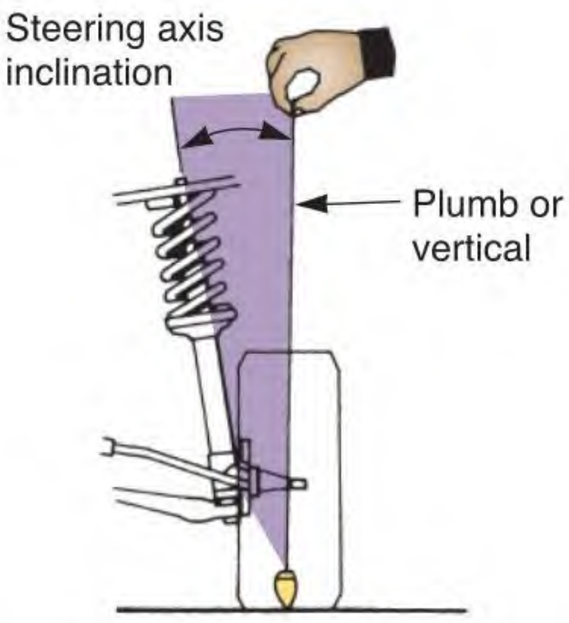
Figure 79-7. Toe is an inward or outward angle of the wheels. Toe-in is produced when the wheels are closer together at the front than at the rear. Toe-out results when the wheels are farther apart at the front than at the rear.

As the tires roll over the road, they are pushed rearward. This turns the tires outward at the front, causing toe-out. By adjusting the wheels for a slight toe-in (approximately 1/16″–1/4″ or 1.6 mm–6 mm), the wheels and tires roll straight ahead when driving.

Front-Wheel-Drive Toe Settings

Front-wheel-drive vehicles require different adjustment for toe. Since the front wheels propel the vehicle, they are pushed forward by engine torque. This makes the wheels toe in, or point inward when the vehicle is driven.

To compensate for this action, front-wheel-drive vehicles normally have front wheels adjusted for a slight toe-out (approximately 1/16″ or 1.6 mm). Theoretically, this will give the front end a zero toe setting when the vehicle moves down the road.



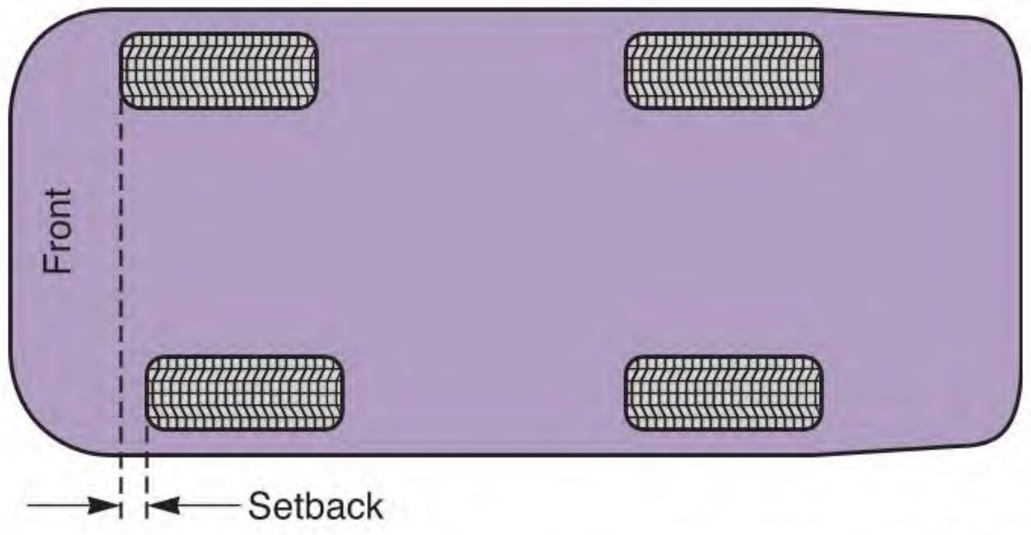
Copyright Goodheart-Willcox Co., Inc.

Steering Axis Inclination

Steering axis inclination is the angle, away from the vertical, formed by the inward tilt of the ball joints, king pin, or MacPherson strut tube. Steering axis inclination is always an inward tilt, regardless of whether the wheel tilts inward or outward. See **Figure 79-8**.

Steering axis inclination is *not* a tire wearing angle. Like caster, it aids directional stability by helping the steering wheel return to the straight-ahead position.

Steering axis inclination is *not* adjustable. It is designed into the suspension system by the vehicle manufacturer. If the angle is *not* correct, you must replace parts to correct the problem.



Bear

Figure 79-8. Steering axis inclination is determined by a vertical line and a projected line through upper ball joint, king pin, or MacPherson strut tube.

Setback

Setback is a condition in which one front wheel is set farther back from the front of the vehicle than the other front wheel. See **Figure 79-9**. When setback is positive, the right wheel is farther back than the left wheel. Negative setback is present when the left wheel is farther back than the right wheel.

Manufacturing tolerances generally allow a small amount of setback. However, excessive setback will cause the vehicle to pull toward the side with the wheel that is the farthest back. Excessive setback is generally the result of collision damage.

Goodheart-Willcox Publisher

Figure 79-9. Setback is present when one front wheel is set farther back than the other front wheel. Excessive setback is an indication of suspension system damage.

Toe-Out on Turns (Turning Radius)

Toe-out on turns, also termed ***turning radius***, is the amount the front wheels toe-out when turning corners. As the vehicle goes around a turn, the inside tire must travel in a smaller radius circle than the outside tire. The steering system is designed to turn the inside wheel sharper than the outside wheel.

Figure 79-10 illustrates toe-out on turns. Note how each front wheel turns at a different angle. This eliminates tire scrubbing and squealing by keeping the tires rolling in the right direction during turns.

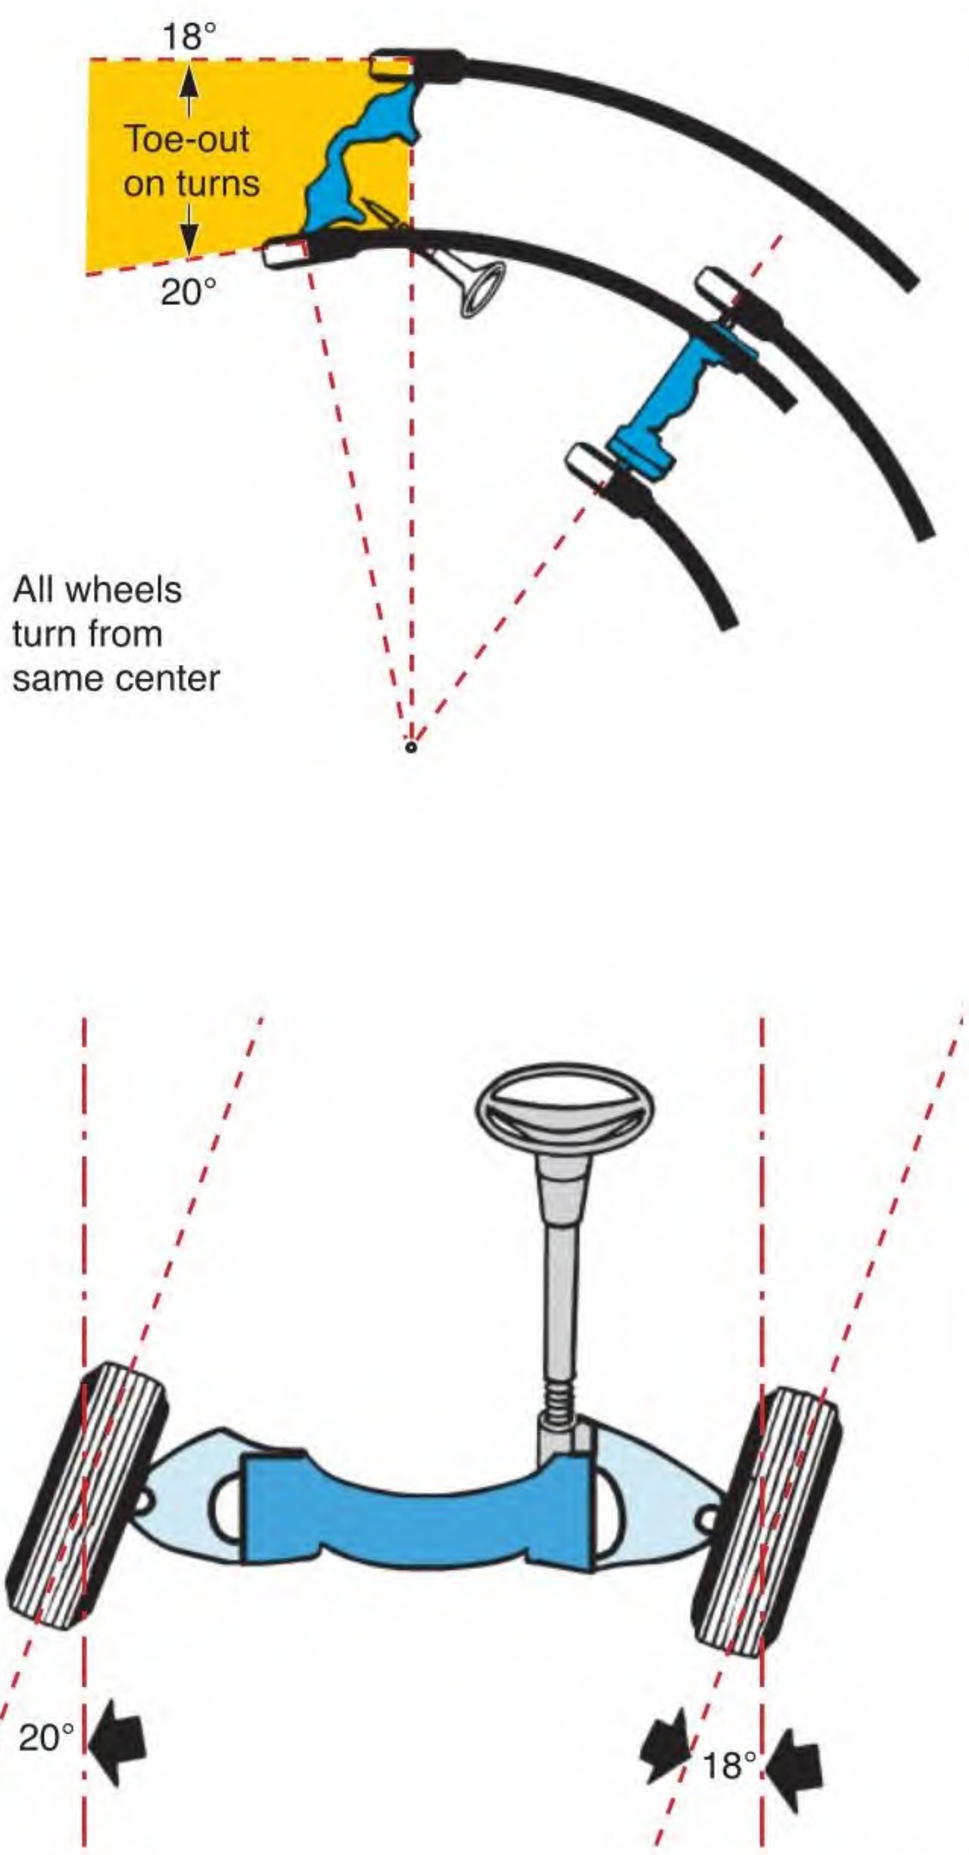
Toe-out on turns is *not* an adjustable angle. It is controlled by the built-in angle of the steering arms. If this angle is incorrect, it indicates bent or damaged steering parts.

Tracking

Tracking refers to the position or direction of the two front wheels in relation to the two rear wheels. With proper tracking, the rear tires follow in the tracks of the front tires, with the vehicle moving straight ahead. Look at **Figure 79-11**.

With improper tracking, or "***dog tracking***," the rear tires do *not* follow the tracks of the front tires. This causes the back of the vehicle to actually shift sideways compared to the front when the vehicle is traveling down the road. Poor tracking will increase tire wear, lower fuel economy, and degrade handling tremendously.

Prealignment Inspection



Before attempting wheel alignment, make sure all steering- and suspension-related parts are in good condition. It is impossible to properly align the wheels on a vehicle with worn or damaged parts.

Copyright Goodheart-Willcox Co., Inc.

You should check for:

- Loose wheel bearings.
- Wheel or tire runout.
- Worn tires.
- Tires of different sizes and types.
- Incorrect tire inflation.
- Worn steering components.
- Worn suspension components.
- Incorrect curb height and weight.
- Incorrect cradle alignment.

Hunter

Figure 79-10. When rounding corners, the inside tire must turn more sharply than the outside tire. Angles built into the steering system produce proper toe-out on turns.

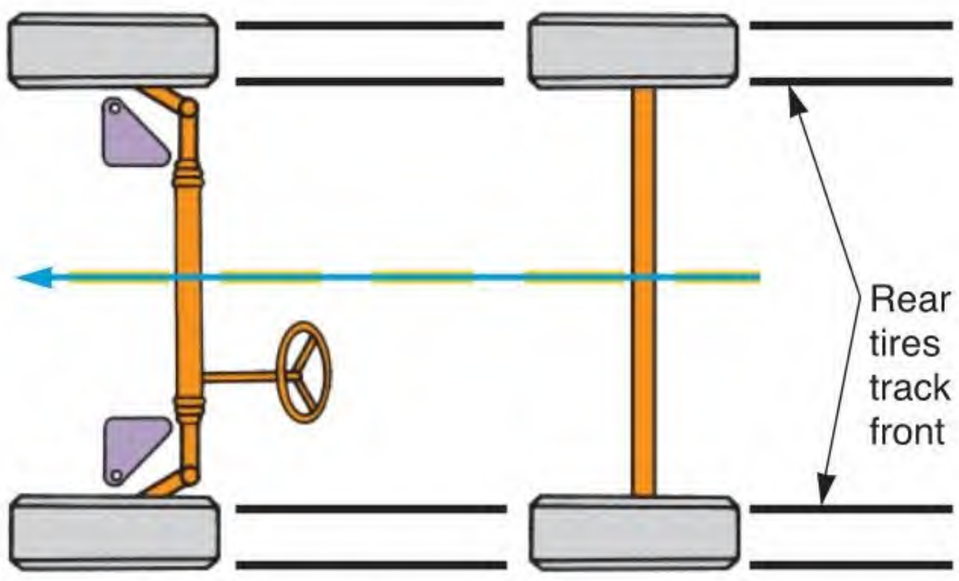


Figure 79-12 shows several components that frequently cause problems during alignment. Adjust or replace worn or damaged parts before doing a wheel alignment. Refer to the text index for details on checking the specific components.

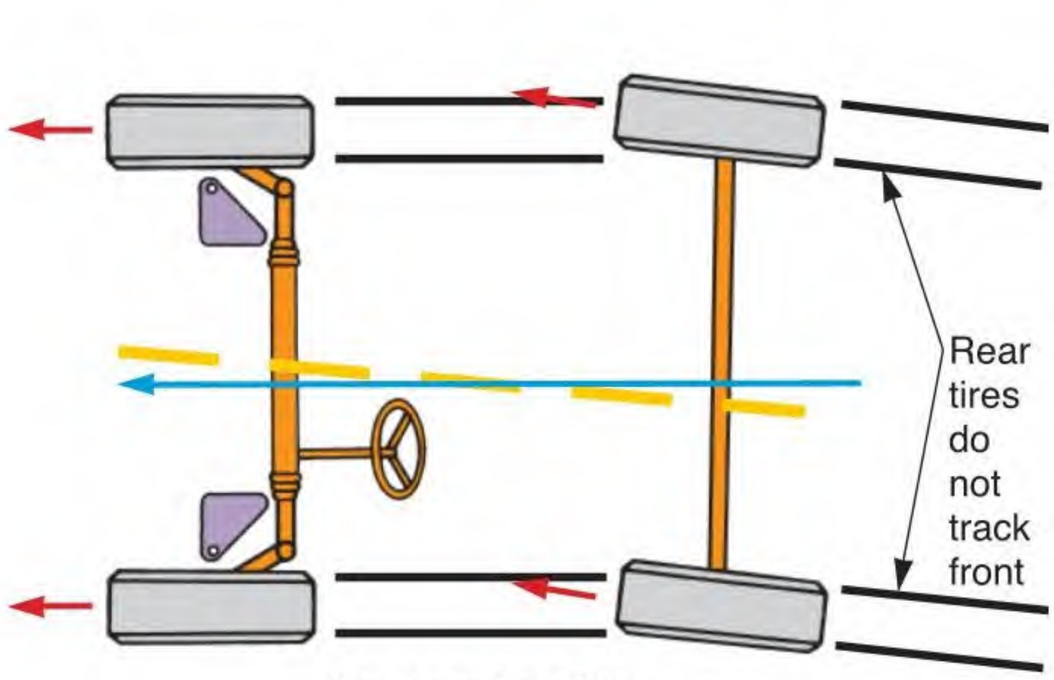
Tech Tip

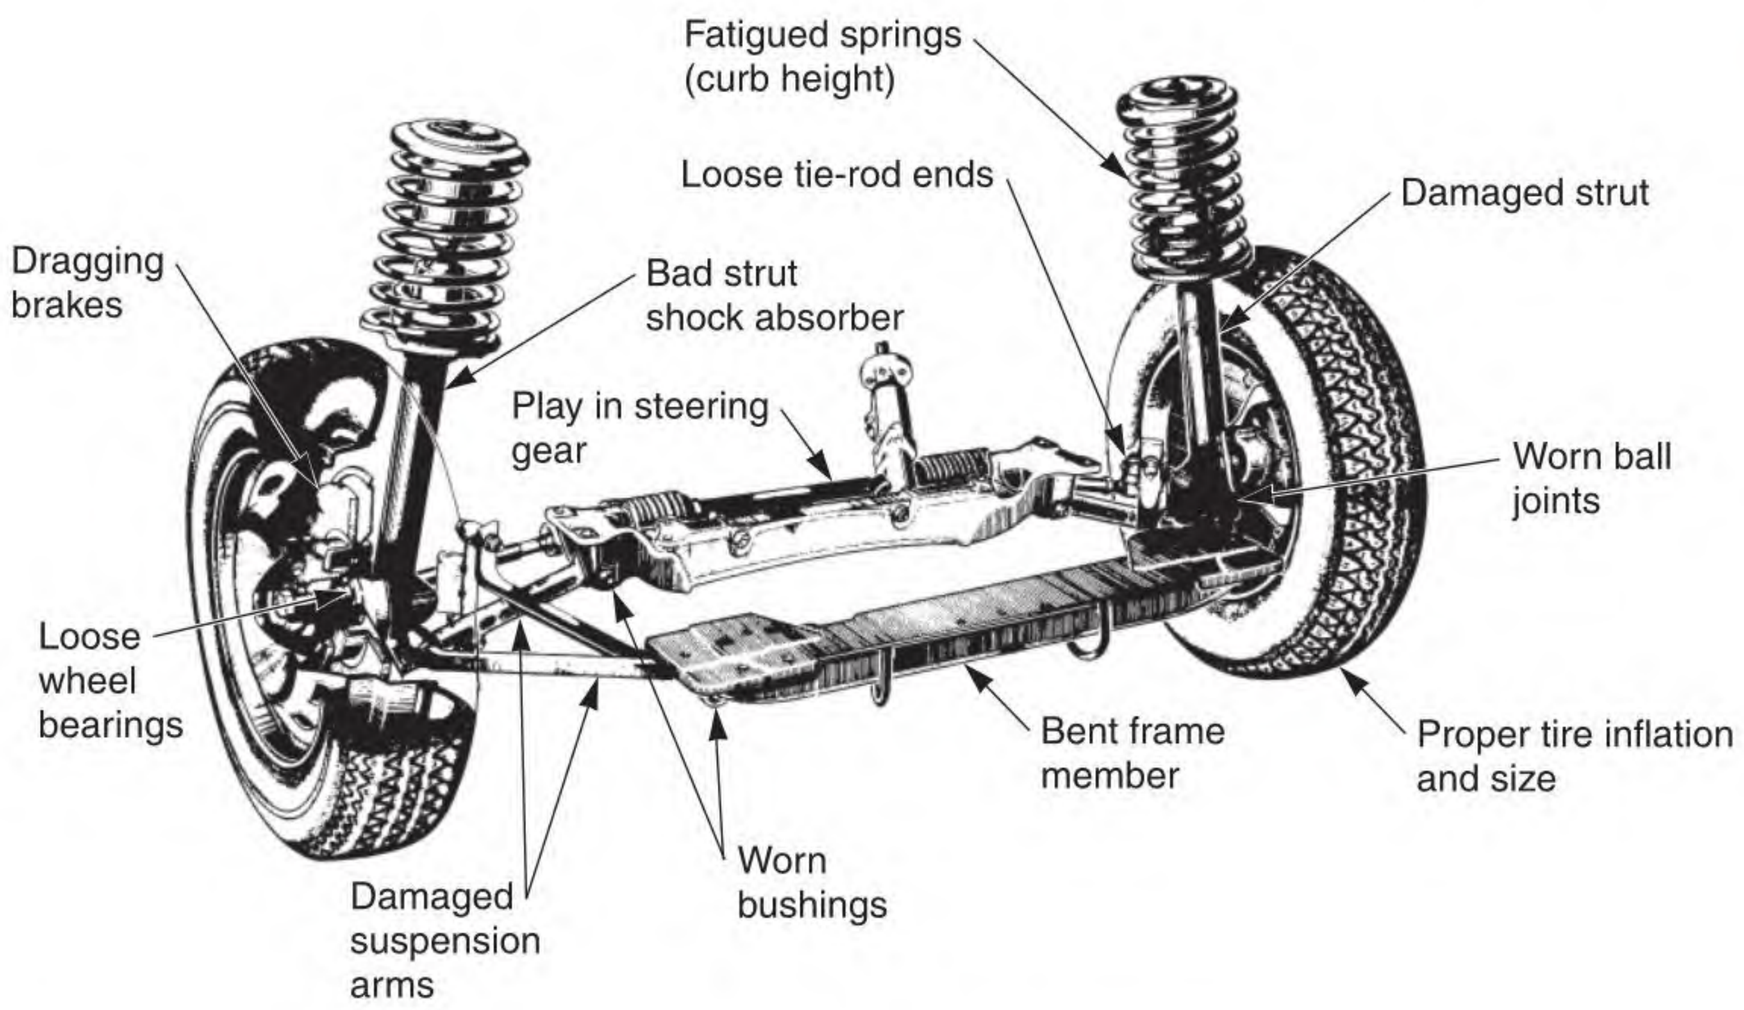


Many technicians like to road test the vehicle before doing a wheel alignment. This allows them to check for the kinds of problems just listed. The road test helps them detect steering wheel pull or play, abnormal noises from worn parts, and similar troubles that could affect wheel alignment.

Reading Tire Wear

Reading tires is done by inspecting tire tread wear and diagnosing the cause for any abnormal

4-wheel alignment



Improper tracking

Goodheart-Willcox Publisher

Figure 79-11. Proper tracking causes the rear wheels to follow directly behind the front wheels.

wear. Note that incorrect camber and toe show up as specific tread wear patterns. **Figure 79-13** shows various tire wear patterns.

Incorrect camber produces wear on one side of the tire tread. Too much negative camber would wear the *inside* of the tire tread. Too much positive camber would wear the *outer* tread only. With correct camber, the *full* tread area will wear evenly.

Incorrect toe will cause a feathered edge to form on the tire tread. A ***feathered edge*** is a tire wear pattern in which one side of each tread rib is sharp and raised and the other side of each rib is rounded or recessed.

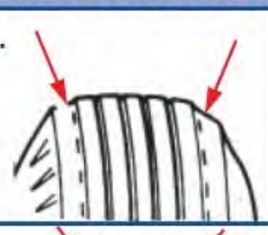
With too much toe-in, the sharp feathered edge points inward (toward the center of the vehicle). With too much toe-out, the sharp edge on the thread ribs points outward.

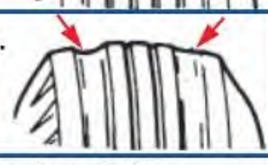
Covered in earlier chapters, tire wear patterns can also indicate incorrect wheel balance, incorrect tire inflation pressure, tire construction defects, and tire damage.

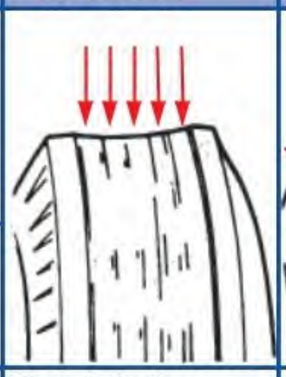
Checking Setback

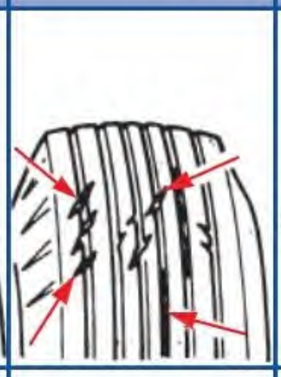
To check for excessive setback, measure the distance from the rear of one front wheel or tire to the inside of the corresponding fender opening. Then, take the same measurement at the other front wheel or tire and compare the two dimensions. In most cases, setback should be 1/4″ (6 mm) or less.

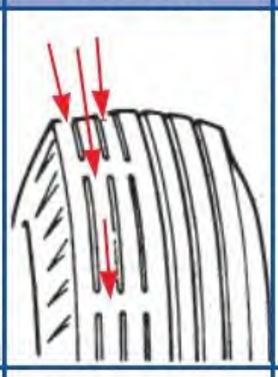
Tech Tip

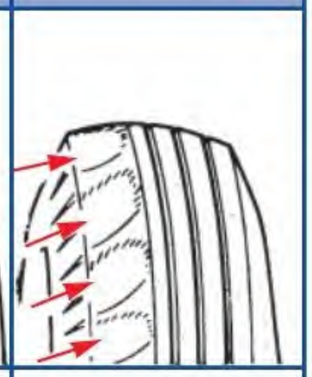


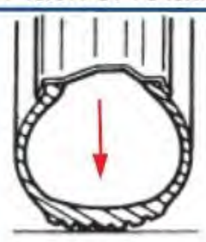












Some manufacturers purposely design a small amount of setback into their vehicles. Refer to appropriate service information for exact specifications.

Setback that is greater than specifications may indicate a bent or damaged suspension component. Cradle misalignment can also cause excessive setback. Identify the problem and make any needed repairs before performing an alignment.

Cradle Alignment

The ***vehicle cradle*** is a strong metal structure mounted at the lower front and sometimes the lower rear of the unibody structure. The thick metal cradle is bolted to the frame rails on the body. The cradle often holds the lower control arms, steering rack, and engine in alignment in the body.

Loosening and moving the cradle can alter wheel alignment (camber, caster, setback, and steering axis inclination). This misalignment might happen

	Rapid wear at shoulders	Rapid wear at center	Cracked treads	Wear on one side	Feathered edge	Bald spots	Scalloped wear
CONDITION	1.  2. 						
CAUSE	Underinflation or lack of rotation 	Overinflation or lack of rotation 	Underinflation or excessive speed	Excessive camber 	Incorrect toe 	Unbalanced wheel  or tire defect	Lack of rotation of tires or worn or out of alignment suspension
CORRECTION	Adjust pressure to specifications when tires are cool, rotate tires			Adjust camber to specifications	Adjust toe-in to specifications	Dynamic or static balance wheels	Rotate tires and check alignment

Chrysler

Copyright Goodheart-Willcox Co., Inc.

after engine or transaxle and cradle removal. A major collision can also shift the cradle and upset wheel alignment.

Improper cradle location can reduce wheel alignment adjustment range. It can also cause premature tire wear, vehicle instability, and incorrect drive line angles.

If you ever remove a cradle, make sure it is reinstalled in the same location. This will help maintain proper wheel alignment. Alignment holes are often provided in the cradle and body. Make sure these holes align when reinstalling or adjusting a cradle. The service manual will give information on proper installation and location of the cradle.

Adjusting the position of the cradle is handy on front-wheel-drive vehicles that do not provide a method of adjusting caster and camber. By shifting the cradle forward, rearward, or to one side, you can alter these angles. Keep this in mind if you run into problems when trying to perform a wheel alignment.

Tech Tip

Before trying to align the wheels of a car, make sure all steering and suspension parts are in perfect working condition. Worn tie-rod ends or sloppy ball joints will have too much play to hold your alignment setting. Worn steering and suspension parts are very dangerous and must be replaced before proceeding with any wheel alignment job.

If the customer will not pay to replace the worn steering or suspension parts, have him or her sign a waiver on the work order. Write down the worn parts on the work order and have the customer sign or initial it before proceeding. This will protect you and your shop from liability if the worn steering or suspension parts fail and cause a serious auto accident later.

Adjusting Wheel Alignment

Caster, camber, and toe are the three commonly adjustable wheel alignment angles.

Before studying wheel alignment equipment, you should have a basic understanding of how alignment angles are changed. Then, you can relate this knowledge to the use of specific alignment equipment.

The basic sequence for wheel alignment is:

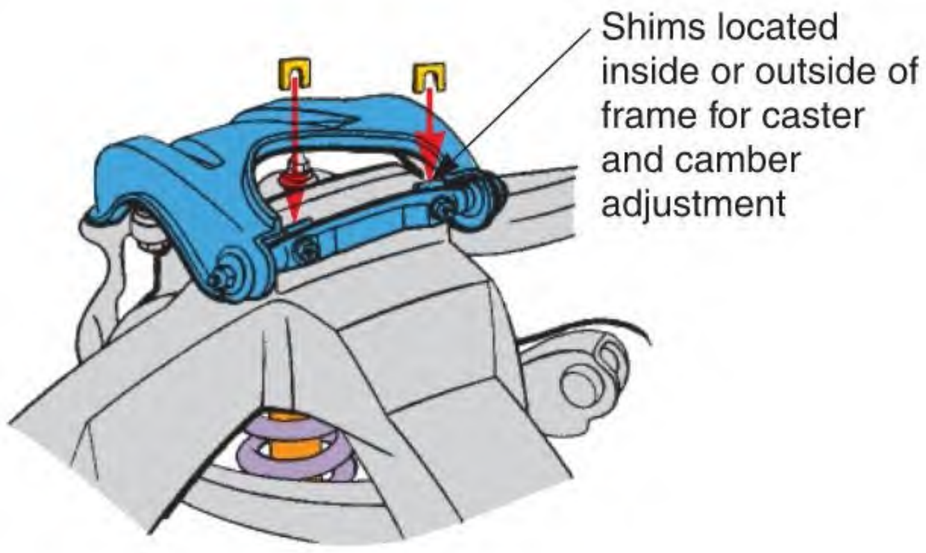
1. Inspect and correct tire, steering, and suspension problems.
2. Adjust caster.
3. Adjust camber and recheck caster.
4. Adjust toe.
5. Check toe-out in turns (needed if there is damage).
6. Check caster, camber, and toe on rear wheels (if needed).
7. Check tracking (if needed).

Caster Adjustment Methods

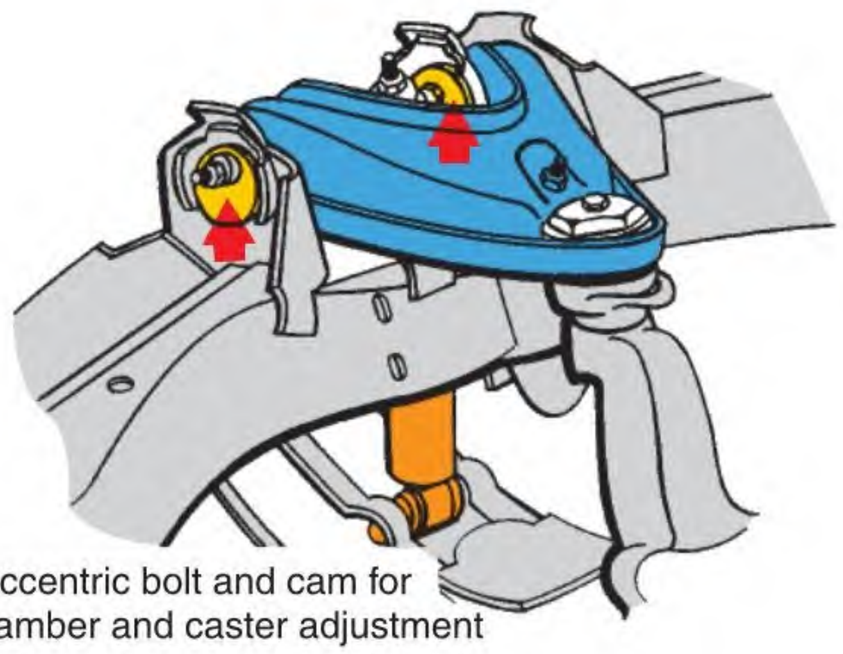
Caster is adjusted by moving the control arm so that the ball joint moves toward the front or rear of the vehicle. Depending on suspension system type, a control arm can be moved by adding or removing ***shims***, adjusting the ***strut rod***, turning an ***eccentric bolt***, or shifting the control arm shaft bolts in ***slotted holes***. See **Figure 79-14**.

If the upper control arm ball joint is moved forward, negative caster is increased, **Figure 79-15A**. If the upper control arm ball joint is moved rearward, positive caster is increased. The opposite is true for the lower control arm.

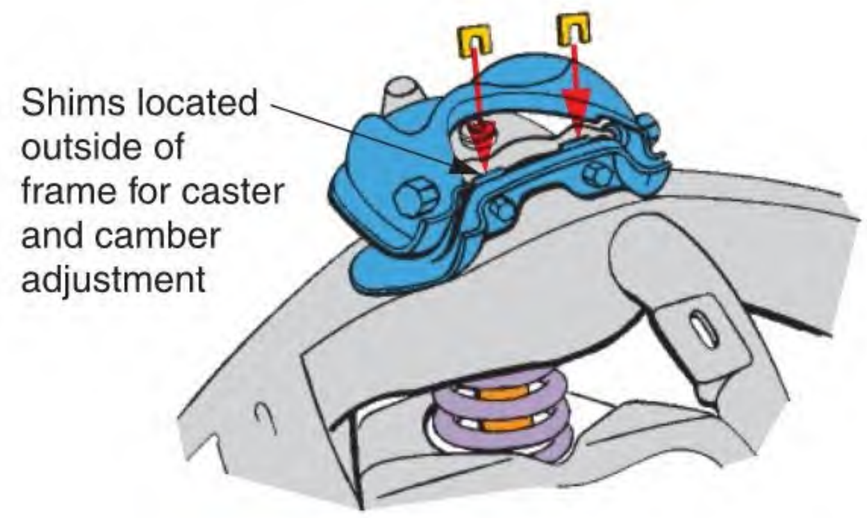
Camber Adjustment Methods



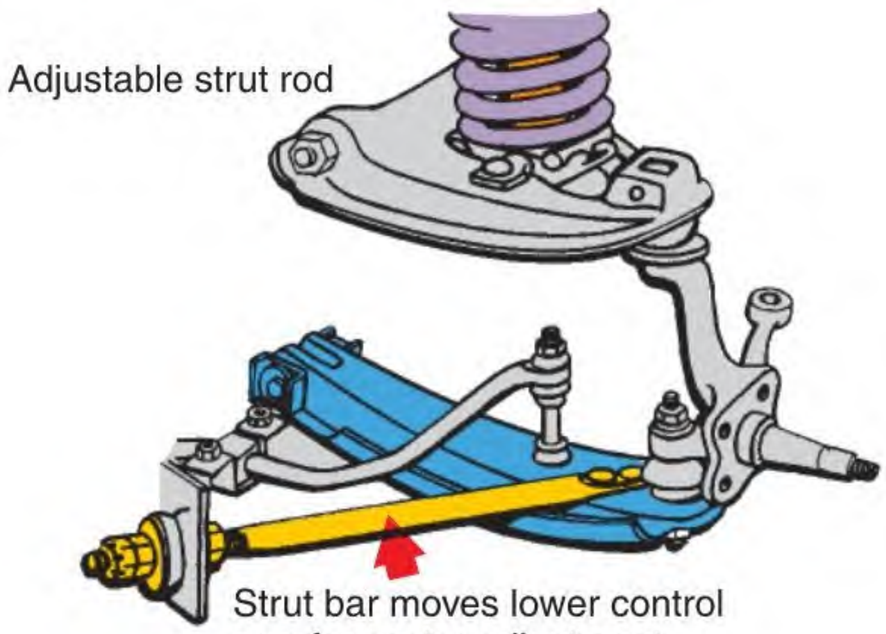
Camber is usually adjusted after setting caster. Camber is changed by moving the control arm in or out *without* moving the ball joint forward or rearward. *Shims* or *slots* in the control arm mount and *eccentric bolts* are the most common methods for adjustment. Refer to **Figure 79-15B**.



Some MacPherson strut suspensions do not have provisions for caster and camber adjustments. However, other strut-type suspension systems have a camber adjustment at the connection between the steering knuckle and strut. The top of the steering knuckle and the bottom of the strut can be pivoted in or out. The upper bolt on the steering knuckle may have an eccentric that moves the knuckle when turned.



Toe Adjustment



Toe is adjusted by lengthening or shortening the *tie-rods*. On most rack-and-pinion steering systems, the tie-rod is threaded into the outer ball socket, **Figure 79-16**. Linkage type steering systems normally have a sleeve that is threaded on a two-piece tie-rod, **Figure 79-17**.

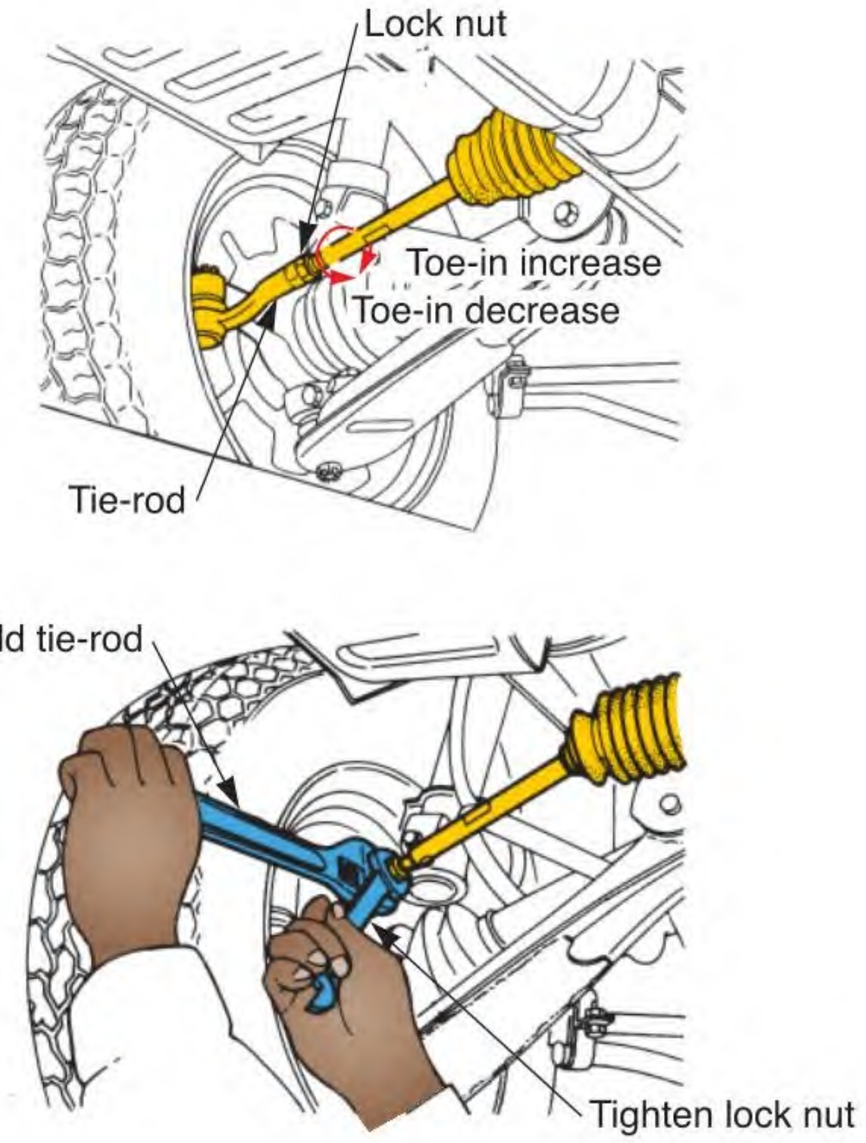
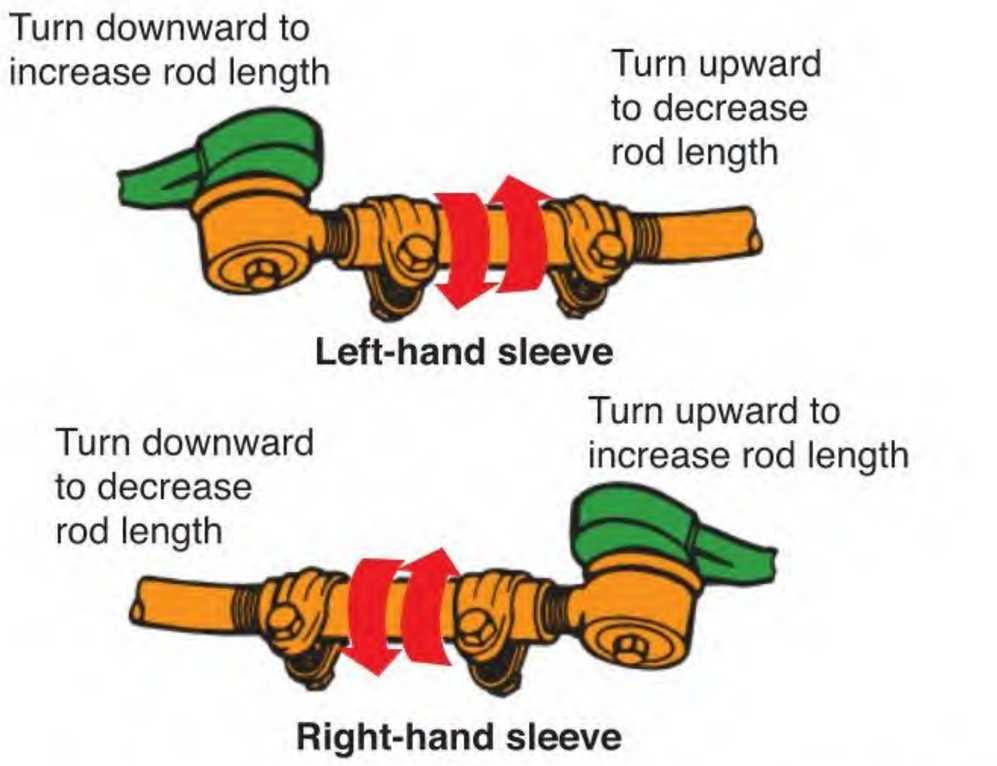
Figure 79-15. A—Caster is adjusted by moving either the upper or lower control arm to the front or rear of the vehicle. B—Camber is adjusted by moving the control arm in or out without moving the ball joint forward or rearward.



When the steering knuckle arms point to the rear of the vehicle, lengthen each tie-rod to increase toe-in and shorten each rod to increase toe-out. The opposite is true when the steering knuckle arms are pointed forward.

Centering Steering Wheel

To keep the steering wheel spokes centered, shorten or lengthen each tie-rod the same amount. Changing one tie-rod more than the other will rotate the steering wheel spokes. When the vehicle is traveling straight ahead, the wheel spokes should be positioned correctly. See **Figure 79-18**.



Adjusting Rear Wheel Alignment

Depending on vehicle make and model, a vehicle may or may *not* have provisions for adjusting rear wheel alignment. If the rear wheels fail to track properly, frame, unibody, or rear suspension damage may be the cause. The vehicle might have been in an accident that shifted the rear wheels out of place. Worn suspension system bushings can also upset tracking. To adjust rear wheel alignment, follow the same principles used for aligning front wheels. **Figure 79-19**

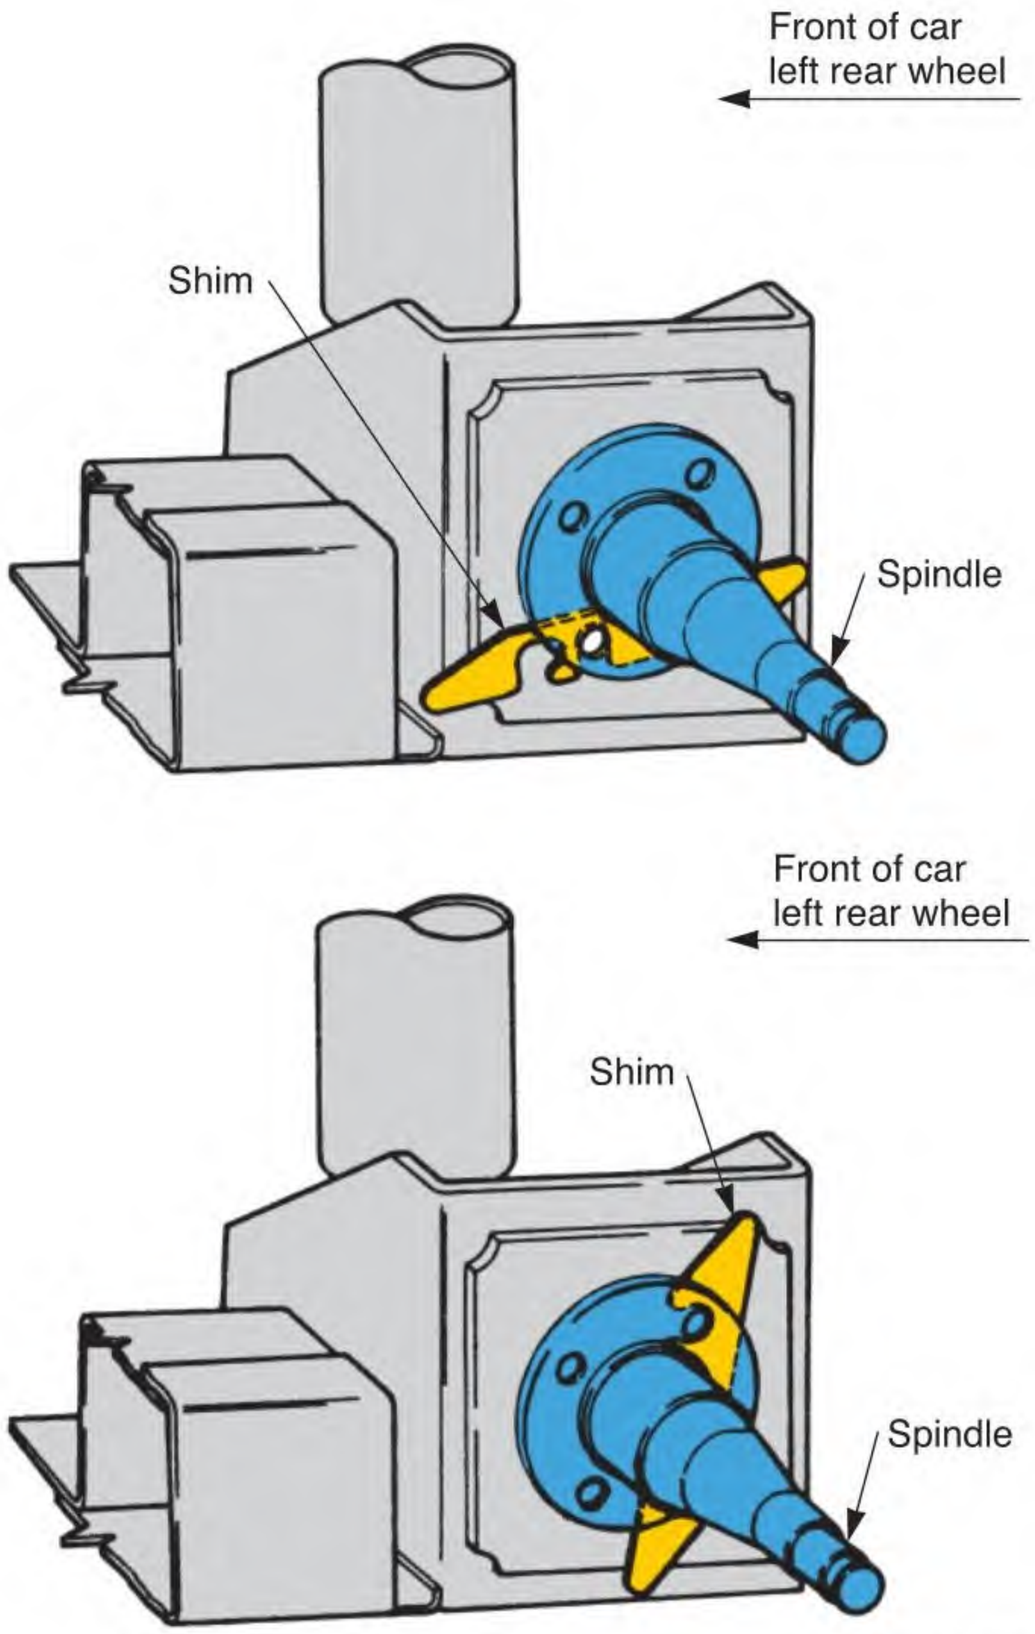
shows how shims can be used to align the rear wheels of one type of front-wheel-drive vehicle. A shim of the correct thickness can be added to adjust camber and toe.

Wheel Alignment Tools and Equipment



Various equipment and special tools are needed to adjust wheel alignment. Several special alignment tools are shown in **Figures 79-20** and **79-21**.

The most basic equipment for wheel alignment is the turning radius gauge, the caster-camber gauge, and the tram gauge. These are the least complicated of all alignment tools and easily illustrate the fundamentals of wheel alignment.

The combined measuring capabilities of these basic pieces of equipment are built into large alignment racks.

Turning Radius Gauges

Turning radius gauges measure how many degrees the front wheels are turned right or left. They are commonly used when measuring caster, camber, and toe-out on turns. Turning radius gauges may be portable units. However, they are commonly mounted and an integral part of an alignment rack.

Chrysler

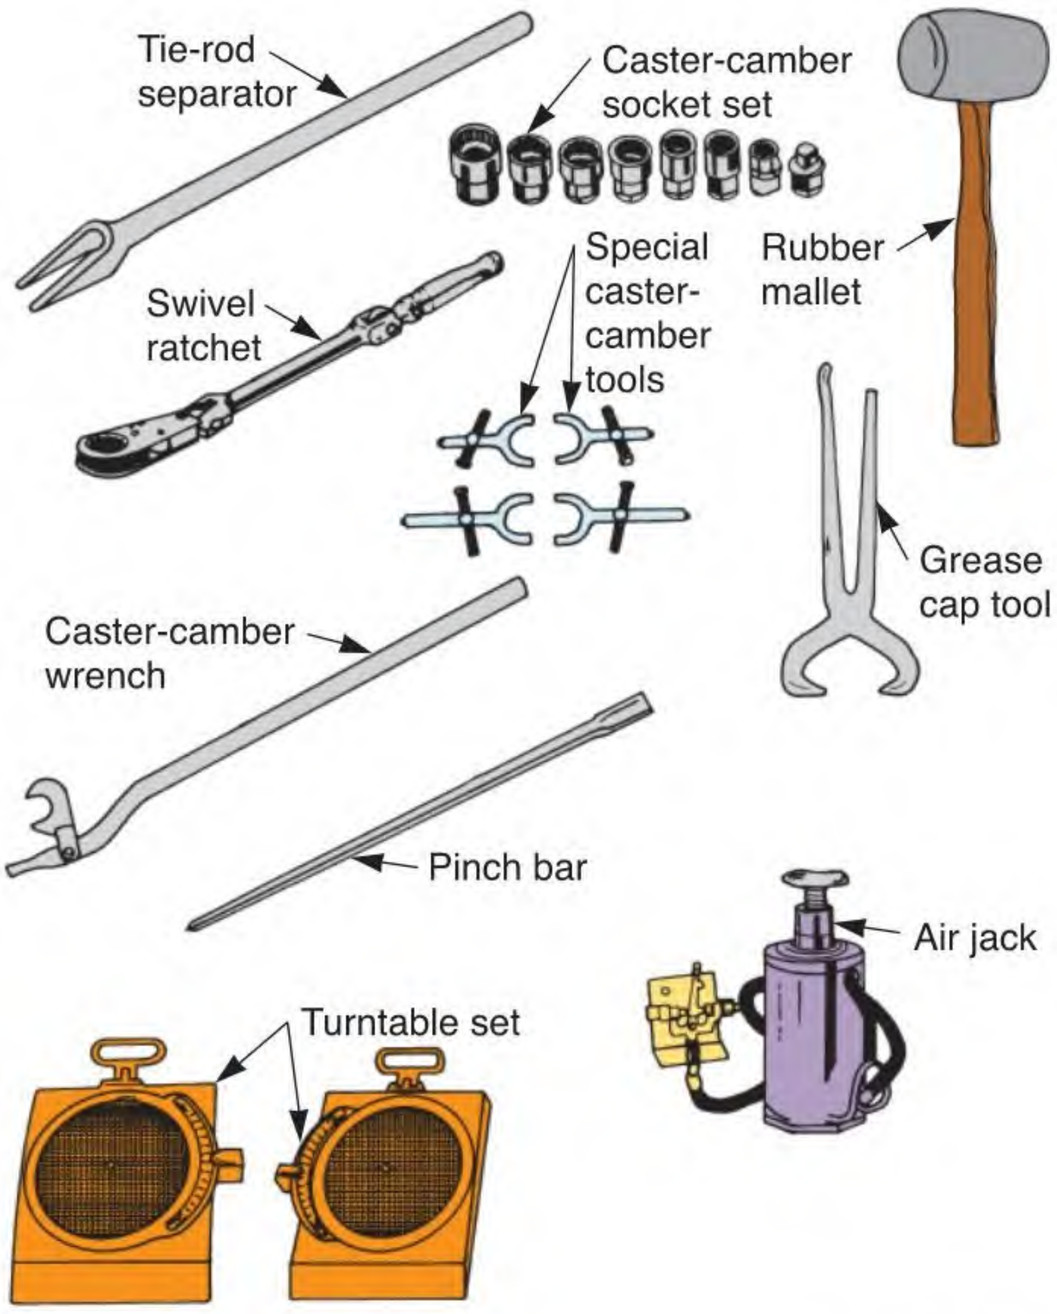


Figure 79-19. Note how a shim can be used to adjust alignment angles on the rear axle of this front-wheel-drive vehicle. Shims can be placed at the bottom, top, front, or rear to change any alignment angle.

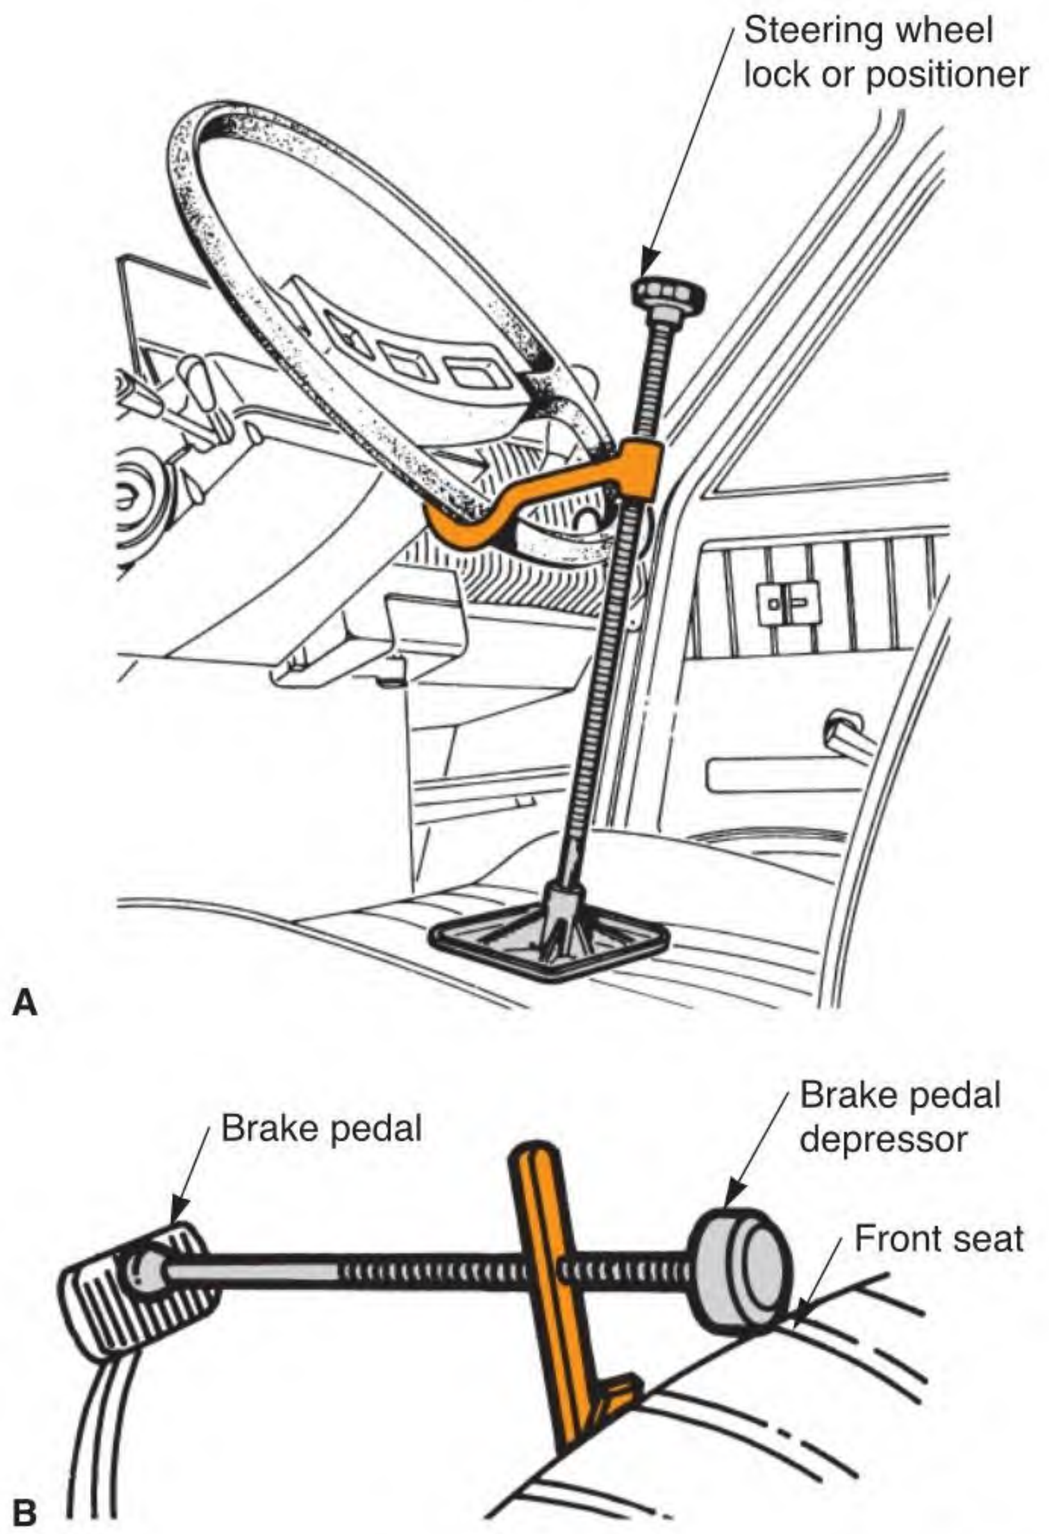
The front wheels of the vehicle are centered on the turning radius gauges. Then, when the locking pins are pulled out, the gauge and tire turn together. The pointer on the gauge will indicate how many degrees the wheels have been turned.

Checking Toe-Out on Turns



To check toe-out on turns, center the front tires of the vehicle on the turning radius gauges. Turn one of the front wheels until the gauge reads 20°. Then, read the number of degrees showing on the other gauge. Check toe-out on turns on both the right and left sides. If toe-out is not within specs, check for bent or damaged parts.

Figure 79-21. A—A steering wheel lock will hold the front wheels straight ahead. B—A brake pedal lock will keep the vehicle from rolling.

Alignment Machines

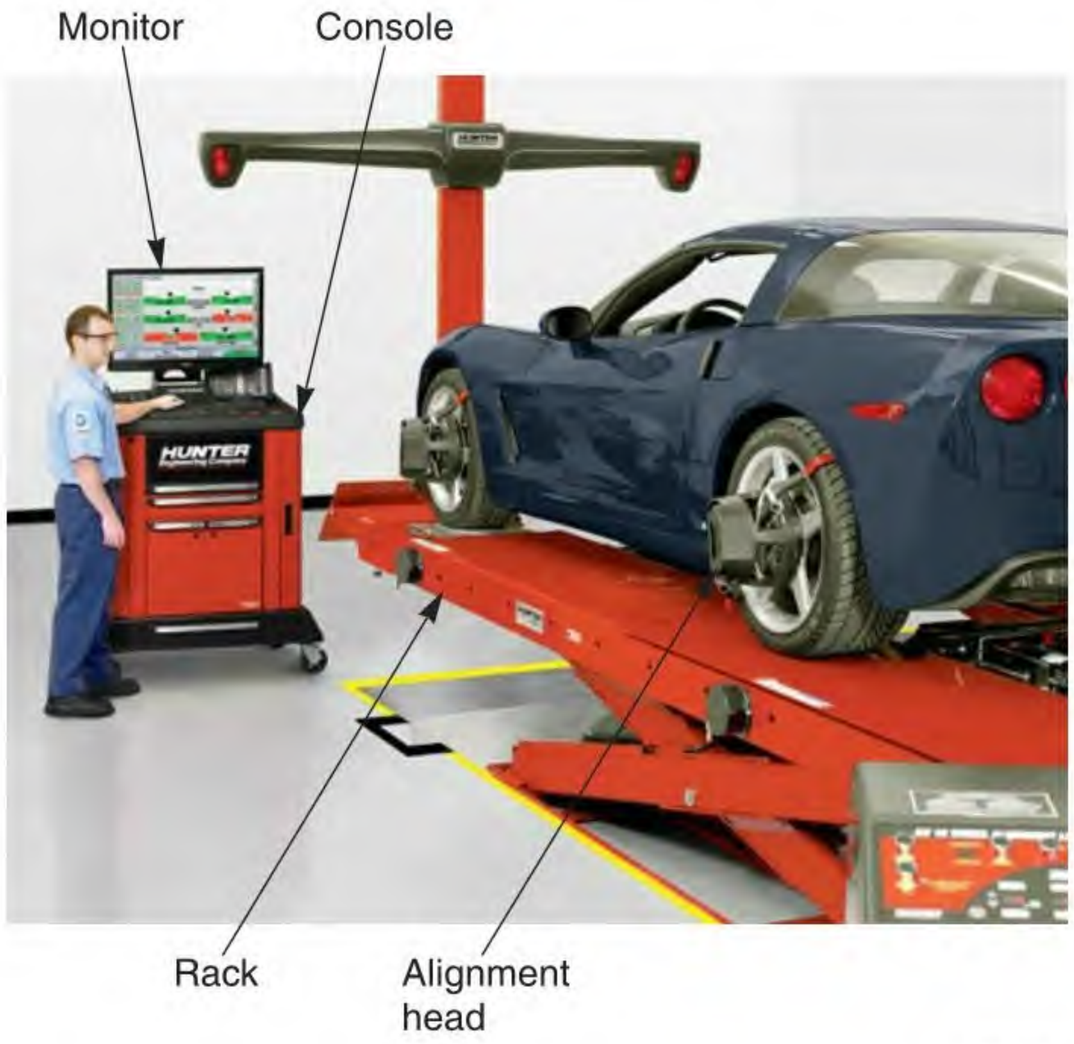
Most medium and large service facilities have alignment machines, or alignment racks. The ***alignment machine*** consists of the rack, console, and related parts.

The ***rack*** is comprised of the ramps, turning radius gauges, and one of several types of equipment for measuring alignment angles. The rack must be perfectly level so that all equipment readings are accurate. A modern ***console*** typically consists of a color monitor, keypad, and computer, all mounted in a roll-around cabinet. Refer to **Figure 79-22**.

Alignment Equipment Software

Alignment equipment software contains computer instructions, information for using the alignment equipment, alignment specifications for various makes and models of vehicles, and other helpful information. When loaded into the console computer, the software will help you adjust all alignment angles quickly and easily. Most software will even give you step-by-step instructions.

The alignment machine software is usually stored on a CD-ROM (compact disc). The information contained in a complete set of manuals can be stored on one CD-ROM.



Depending on the type of the alignment machine, the monitor may prompt you to do a vehicle inspection before attempting wheel alignment.

Alignment Heads

Alignment heads mount on the vehicle wheels and are used to check caster, camber, and toe. They often use lasers or proximity sensors to compare the alignment of each wheel. Refer to **Figure 79-23**.

Special brackets are used for mounting the alignment heads on the wheels. Sometimes the brackets are an integral part of the heads.

Hunter

Figure 79-22. A modern alignment machine contains a dedicated computer, console, large screen monitor, and wheel alignment heads for quickly reading and adjusting alignment angles.

Hunter

Figure 79-23. Make sure wheel alignment head is properly installed on wheel and strapped to tire or wheel so it cannot fall off and be damaged.

Using Alignment Equipment

Since there are so many types of alignment equipment, always follow the operating instructions provided by the manufacturer. Remember that alignment principles are the same regardless of the equipment used. Apply your knowledge of wheel alignment to the specific type of equipment.

To use an alignment rack, drive the vehicle up on the ramps. Carefully center the front tires on the turning radius gauges. Once the vehicle is positioned on the rack, block the rear wheels to keep the vehicle from accidentally rolling off the ramps.

Warning

Use extreme care when positioning a vehicle on an alignment rack. Ask a friend to guide you up the ramps and onto the turning radius gauges. Always block the rear wheels! If a vehicle falls off an alignment rack, it could kill you or a co-worker.

Today's computerized alignment equipment is easy to use. Mount the alignment heads on the vehicle wheels. For a two-wheel alignment, only mount the heads on the front wheels. For an all-wheel alignment, mount heads on all four wheels.

After turning on the alignment console, the computer might prompt you to enter the make, model, year, and other information about the car or truck. After you have keyed in the needed information, the computer will retrieve stored data about performing an alignment on the vehicle at hand, **Figure 79-24**.

The monitor will then let you select different equipment functions, including:

- Training on equipment.
- Inspection of vehicle.
- Vehicle specifications.
- Vehicle measurements.
- Vehicle adjustment locations and procedures.
- Printing out work order or measurements.
- Using help functions for additional information.

Most modern alignment equipment is "***icon***" based, which means it uses small pictures to help you operate the equipment. Both words and pictures give you the feedback needed to successfully use the equipment.

Copyright Goodheart-Willcox Co., Inc.

Hunter

Figure 79-24. This technician is using a remote control to reset steering sensors while watching the monitor for instructions. The remote control interfaces with the vehicle's OBD-II system and communicates wirelessly with the alignment console.

As you make alignment adjustments, the equipment monitors the changes in the alignment angles. It shows you how much you have changed the wheel alignment and informs you when your adjustments are within specs. You can watch the monitor to check your progress. See **Figure 79-25**.

Caution

Always remember to use the operating manual provided with the specific alignment equipment. Procedures vary, and the slightest mistake could upset proper wheel alignment.

Hunter

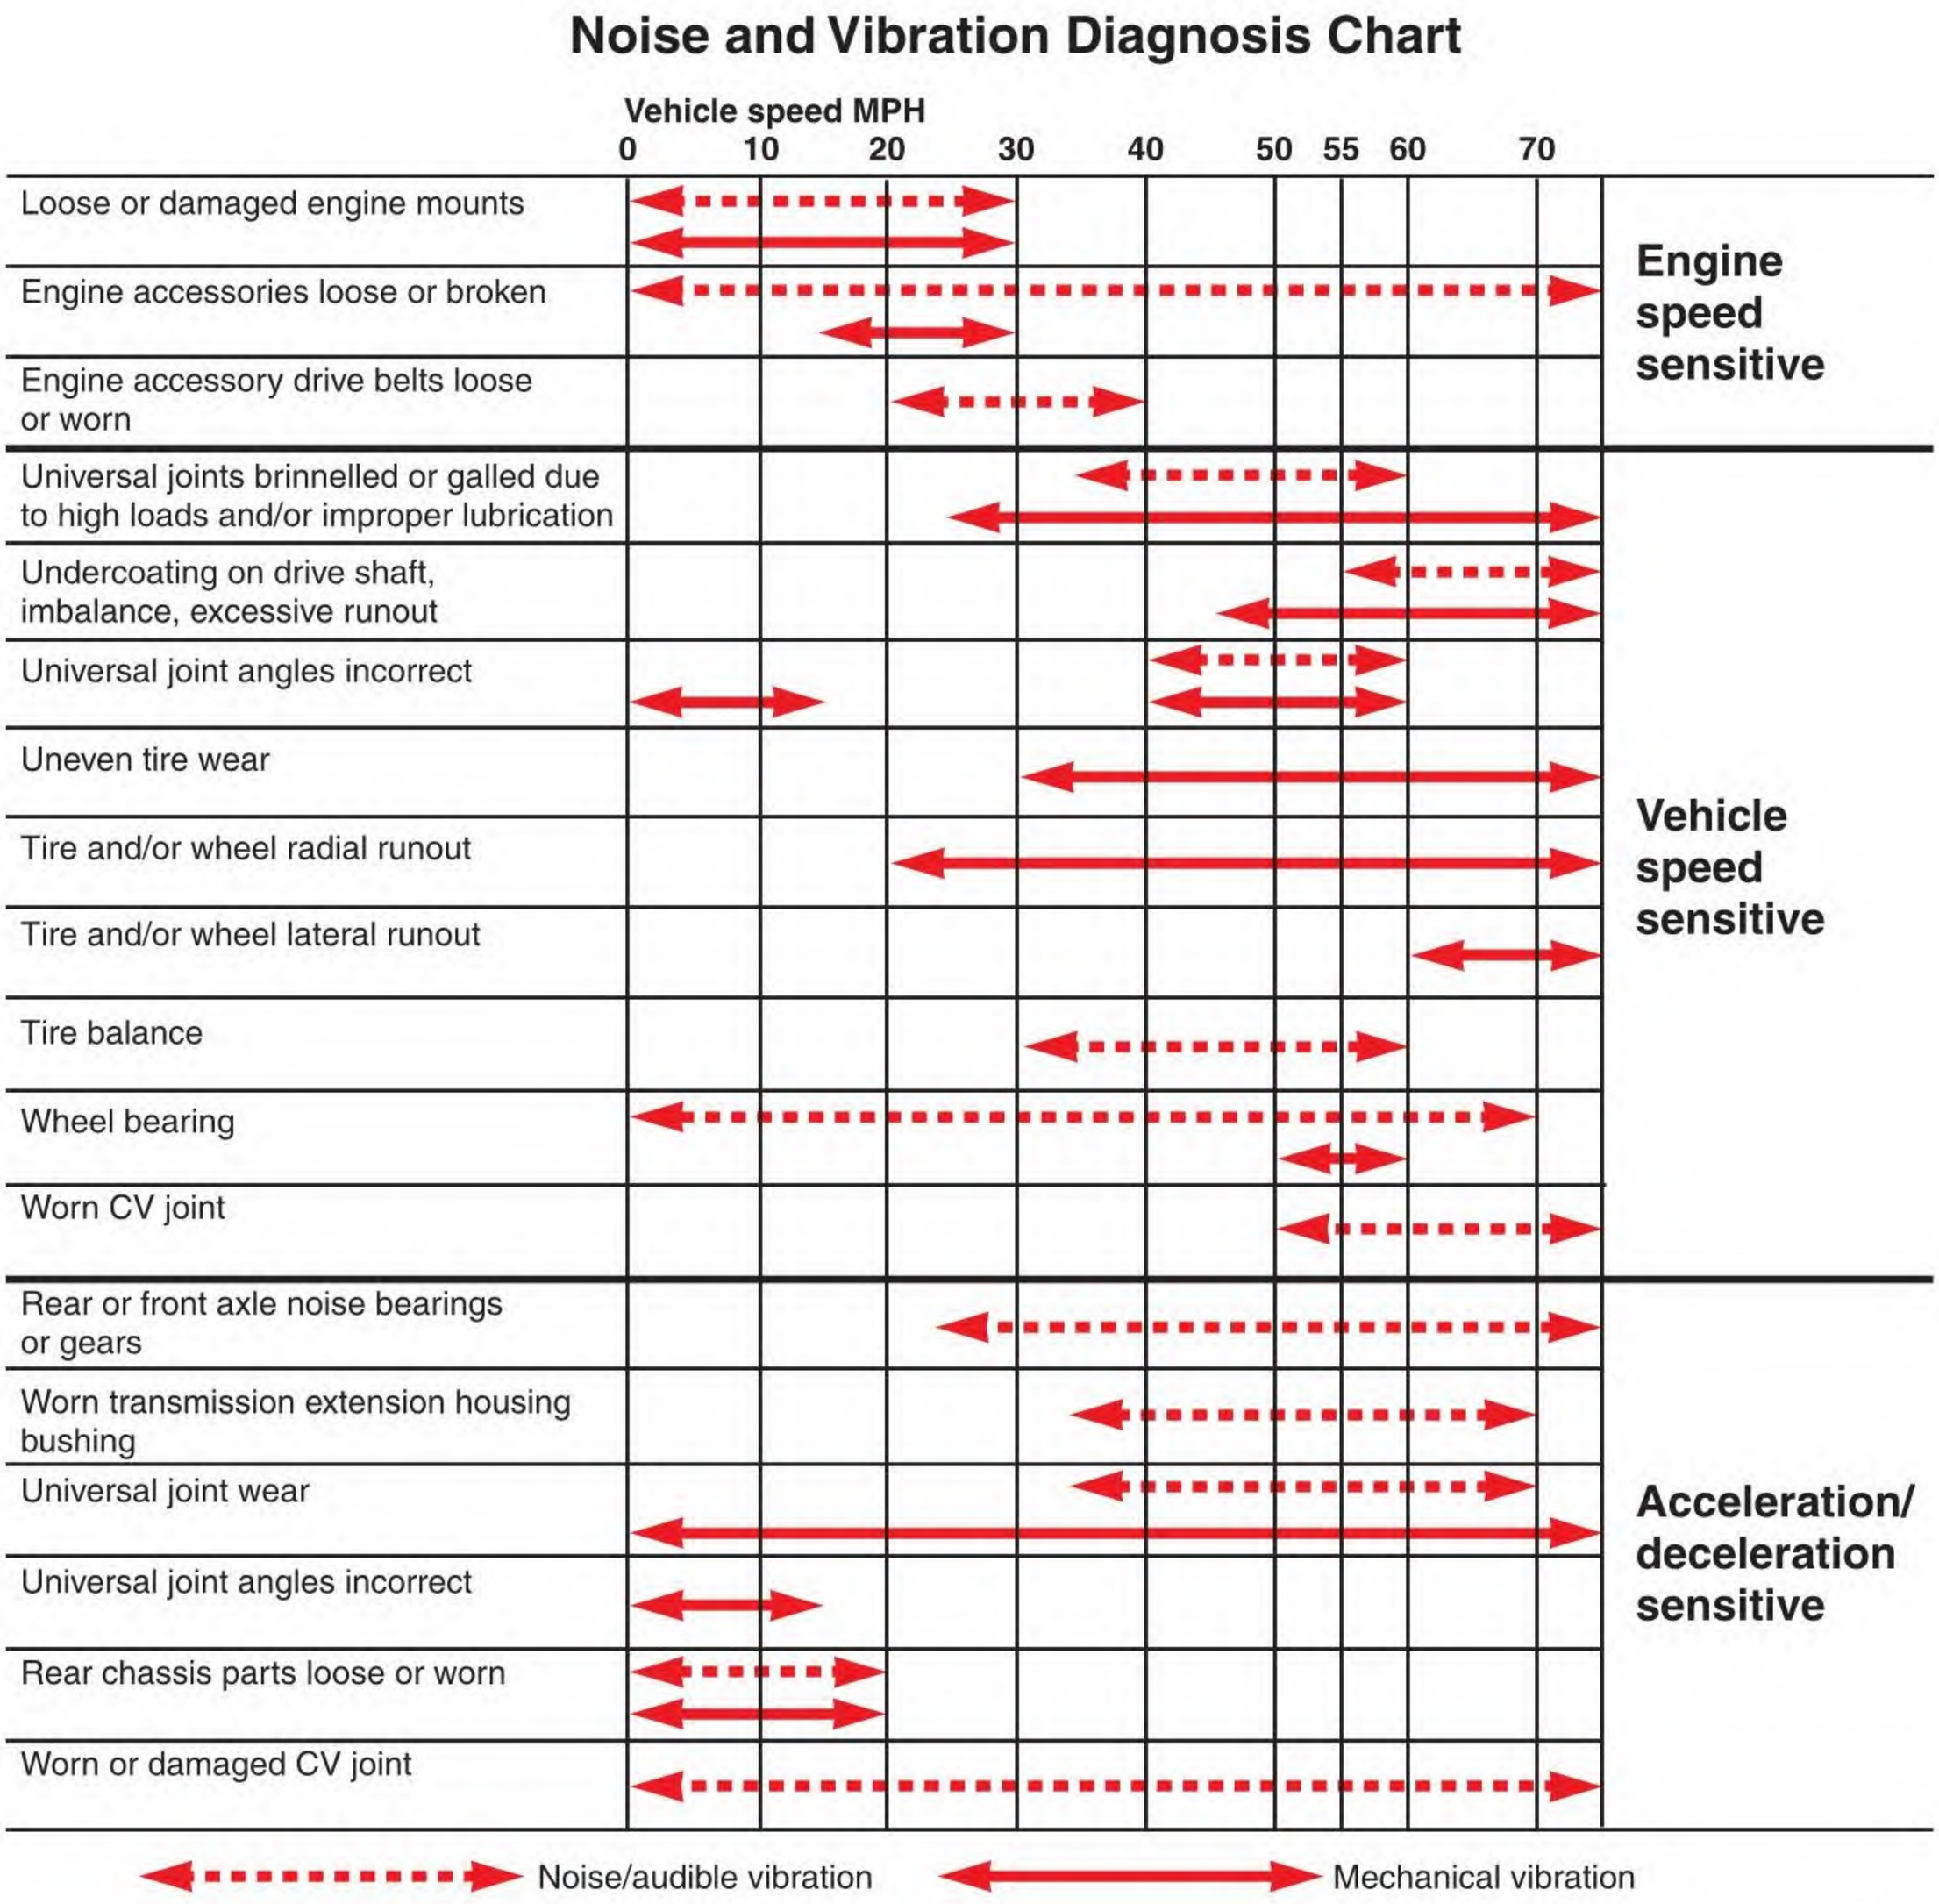
Figure 79-25. This alignment machine provides a graphic display of the alignment readings for each wheel.

Road Test after Alignment

After completing the wheel alignment, you should road test the vehicle to check your work. As you test-drive the car or truck on level pavement, check for a misaligned steering wheel, steering wheel pull, and similar troubles. If you detect problems, alter your alignment adjustments to correct any troubles.

A chart outlining noise and vibration problems is shown in **Figure 79-26**. Make sure the vehicle is not suffering from any of these problems before releasing it to the customer.

Diagnostic Case Study



Concern: Mr. Smith enters the shop and says that the new tires he purchased from another shop have worn out even though he has put less than 1000 miles on them. He wants proof that the tires are defective. When asked, he says that he has not had a wheel alignment since he purchased the car several years ago.

Cause: Duff inspects the tires. He notices feathered edge wear on the front tires caused by improper toe adjustment. The inner edges of the tires are also worn more than the rest of the tire tread, indicating improper camber adjustment. Duff explains to the customer that the vehicle has an alignment problem and that the tires are not defective. He also informs the customer that the front tires should be replaced before the vehicle is aligned. The customer reluctantly agrees, and Duff turns the car over to the shop's suspension and steering technician.

Correction: The technician replaces the vehicle's front tires and then sets up the car on the wheel alignment machine. The readings show that the front wheels are toed out even though specifications call for a slight toe-in. The wheels also have excessive negative camber.

The technician loosens the nuts on the upper strut tower and shifts the strut to adjust the camber to specifications. Next, he rotates the tie-rod ends until toe is set to the manufacturer's specifications. The caster settings are within specifications and do not require adjustment. The car is test-driven to check for pull and then released to the customer.

Summary

- The main purpose of wheel alignment is to make the tires roll without scuffing, slipping, or dragging under all operating conditions.
- Caster is basically the forward or rearward tilt of the steering knuckle (spindle support) when viewed from the side of the vehicle.
- Road crown is the normal slope toward the outer edge of the road surface.
- Camber is the inward or outward tilt of the wheel and tire assembly when viewed from the front of the vehicle.
- Toe is determined by the difference in distance between the front and rear of the left- and right-hand wheels.
- Front-wheel-drive and rear-wheel-drive vehicles normally require much different toe settings.
- Steering axis inclination is the angle, away from the vertical, formed by the inward tilt of the ball joints, king pin, or MacPherson strut tube.
- Toe-out on turns, also termed turning radius, is the amount the front wheels toe-out when turning corners.
- Tracking, also called thrust line, refers to the position or direction of the two front wheels in relation to the two rear wheels.
- Reading tires is done by inspecting tire tread wear and diagnosing the cause for any abnormal wear.
- Camber is usually adjusted right after setting caster.
- Toe is adjusted by lengthening or shortening the tie-rods.
- Turning radius gauges measure how many degrees the front wheels are turned right or left.
- A caster-camber gauge is used with the turning radius gauge to measure caster and camber in degrees.
- The alignment rack consists of ramps, turning radius gauges, and one of several kinds of equipment for measuring alignment angles.
- A modern alignment console typically consists of a color monitor, keypad, and computer, all mounted in a roll-around cabinet.
- Alignment heads mount on the vehicle wheels to check caster, camber, and toe.
- After completing your wheel alignment, you should road test the vehicle to check your work.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

alignment

Review Questions

Answer the following questions using the information provided in this chapter.

1. Define the term *alignment*.
2. What is the main purpose of wheel alignment?
3. _____ is the forward or rearward tilt of the steering knuckle or steering support when viewed from the side of the vehicle.
4. List the three basic functions of caster.
5. Explain the difference between positive and negative caster.
6. Which of the following pertains to caster?
   (A) Measured in degrees.
   (B) A directional control angle.
   (C) Can be used to offset road crown.
   (D) All of the above.
7. _____ is the inward or outward tilt of the wheel and tire assembly when viewed from the front of the vehicle.
8. List three functions of camber.
9. Explain the difference between positive and negative camber.
10. Most vehicle manufacturers suggest a slight negative camber setting. True or False?
11. _____ is determined by the distance between the front and rear of the left- and right-hand wheels.
12. Explain the difference between toe-in and toe-out.
13. Rear-wheel-drive cars commonly use toe-in and front-wheel-drive cars commonly use toe-out. True or False?
14. Define the term *tracking*.
15. Name seven possible problems you should check before attempting to align a vehicle's front end.
16. _____ _____ is done by inspecting tread wear and diagnosing the cause of abnormal wear.
17. List the seven basic steps for wheel alignment.
18. How do you change caster?
19. How do you change camber?
20. How do you adjust toe?
21. Turning radius gauges measure how many degrees the front wheels are turned right or left. True or False?
22. What is an alignment console?
23. What is an alignment rack?

ASE-Type Questions

1. Technician A says correct wheel alignment can improve an automobile's handling ability. Technician B says correct wheel alignment can improve an automobile's fuel economy. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says one of the main functions of wheel alignment is to make the tires roll without slipping under all operating conditions. Technician B says one of the main functions of wheel alignment is to adjust for badly worn steering parts. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says the term "caster" refers to the forward or rearward tilt of the steering knuckle when viewed from the side of the car. Technician B says the term "caster" refers to the forward or rearward tilt of the tie-rod when viewed from the side of the car. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says cars with manual steering have more "negative" caster than cars with power steering. Technician B says cars with power steering have more "negative" caster than cars with manual steering. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

5. Technician A says one of the purposes of caster is to aid directional control of the vehicle. Technician B says one of the purposes of caster is to load the larger inner wheel bearing. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. A car's steering wheel does not return to the straight-ahead position after turning. Technician A adjusts the automobile's caster angle. Technician B says the car's caster angle has nothing to do with this problem. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A tilts the top of a car's steering knuckle toward the rear of the car to adjust for "positive" camber. Technician B tilts the top of the tie-rod toward the front of the car to adjust for "positive" caster. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says camber is the inward or outward tilt of the wheel and tire assembly when viewed from the front of the car. Technician B says camber is the inward or outward tilt of the steering knuckle when viewed from the front of the car. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says with "positive" camber, the tops of the wheels tilt outward when viewed from the front of the car. Technician B says with "positive" camber, the tops of the wheels tilt inward when viewed from the front of the car. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A normally adjusts a car's positive camber setting at about 1/4° to 1/2°. Technician B normally adjusts a car's positive camber setting at about 3° to 4°. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. Technician A says "toe-in" is produced when the front of the wheels are closer together than the rear of the wheels. Technician B says "toe-in" is produced when the front of the wheels are farther apart than the rear of the wheels. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. Technician A says a rear-wheel-drive car's toe-in setting should be 1/16″ to 1/4″. Technician B says a rear-wheel-drive car's toe-in setting should be 1.6 mm to 6 mm. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. An automobile needs a wheel alignment. Before performing this task, Technician A checks for loose wheel bearings. Before performing this task, Technician B checks for wheel or tire runout. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. Technician A adjusts an automobile's camber angle to help prevent tire wear on the inner or outer tread. Technician B adjusts an automobile's caster angle to help prevent tire wear on the inner or outer tread. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
15. Technician A adjusts a car's toe angle by lengthening or shortening the steering knuckle. Technician B adjusts a car's toe angle by lengthening or shortening the tie-rods. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Section 13

Brake System Technology

Chapter 80
Brake System Technology

Chapter 81
Brake System Diagnosis, Service, and Repair

Chapter 82
Anti-Lock Brakes, Traction, and Stability Control

An automotive brake system must be capable of bringing thousands of pounds of steel and plastic to a quick and controlled halt. To stop the vehicle, hydraulic brake systems convert mechanical energy (rotation of wheels) to heat energy. Hybrid vehicles use a regenerative braking system to assist the hydraulic brakes. These systems help slow the vehicle while converting the mechanical energy of the rotating wheels to electrical energy to help power the vehicle. A properly functioning brake system is imperative to safe vehicle operation.

Section 13 covers the construction, operation, service, and repair of all types of automotive braking systems. It includes detailed information on brake system hydraulics, disc brakes, drum brakes, anti-lock brakes, and regenerative braking systems, as well as traction control systems and stability control systems. This section will help you pass ASE Test A5, *Brakes*.

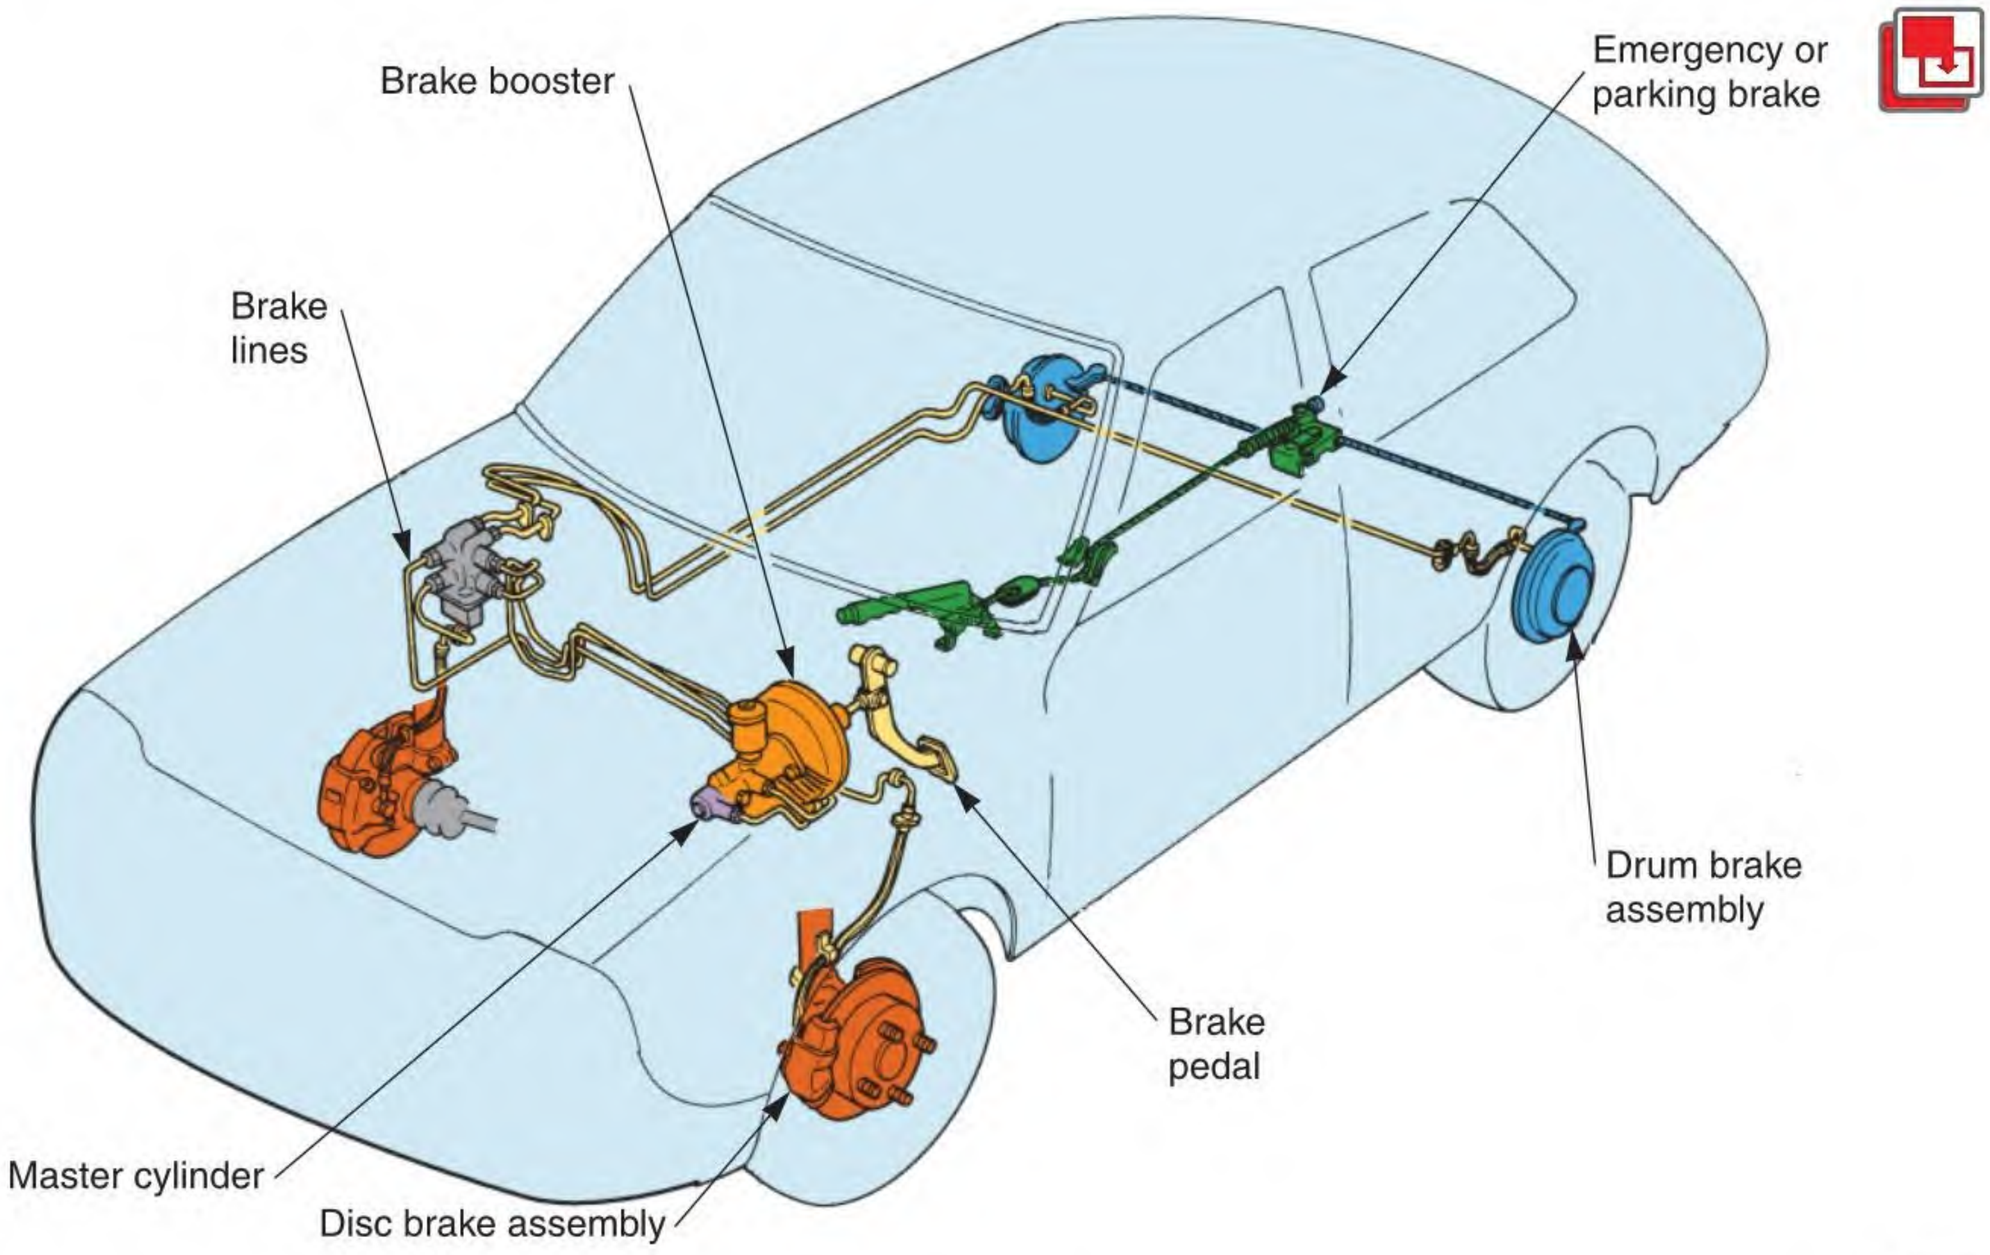
Chapter 80
Brake System Technology

After studying this chapter, you will be able to:

- Explain the hydraulic and mechanical principles of a brake system.
- Identify the major parts of an automotive brake system.
- Define the basic functions of the major parts of a brake system.
- Compare drum and disc brakes.
- Explain the operation of power brakes.
- Describe the operation of parking brakes.
- Correctly answer ASE certification test questions requiring a knowledge of automotive brake systems.

Automotive brakes provide a means of using friction to either slow, stop, or hold the wheels of a vehicle. When a car is moving down the highway, it has a tremendous amount of stored energy in the form of ***inertia*** (tendency to keep moving). To stop the vehicle, the brakes convert mechanical energy (rotation of wheels) into heat energy.

With ***hydraulic brakes***, confined brake fluid is used to transfer power and motion from the brake pedal to the wheel cylinders and brakes. The foot brake pedal acts on a hydraulic master cylinder, which sends fluid pressure to the hydraulic wheel cylinders. The wheel cylinder pistons then slide outward to push the brake pads into the spinning brake discs.



With ***hybrid brakes***, a conventional hydraulic brake system is combined with an electric regenerative braking system provided by the hybrid's driveline. The motor-generator serves as a high-power ac generator that requires considerable torque to rotate. The torque needed to spin the motor-generator places a drag on the driveline to help slow the vehicle while recharging the HV battery. All modern hybrids have regenerative braking to increase gas mileage ratings.

As you will learn, a modern automobile uses numerous devices to improve braking ability. For example, dual hydraulic brake systems that prevent total loss of braking, hydraulic valves that control pressure to each wheel brake, and electronic anti-lock braking systems that prevent tire spin on slippery pavement are all standard equipment.

Basic Brake System

Before studying the construction and operation of individual brake system parts, you should have a general understanding of overall system design and operation. The basic parts of an automotive brake system include:

Copyright Goodheart-Willcox Co., Inc.

Honda

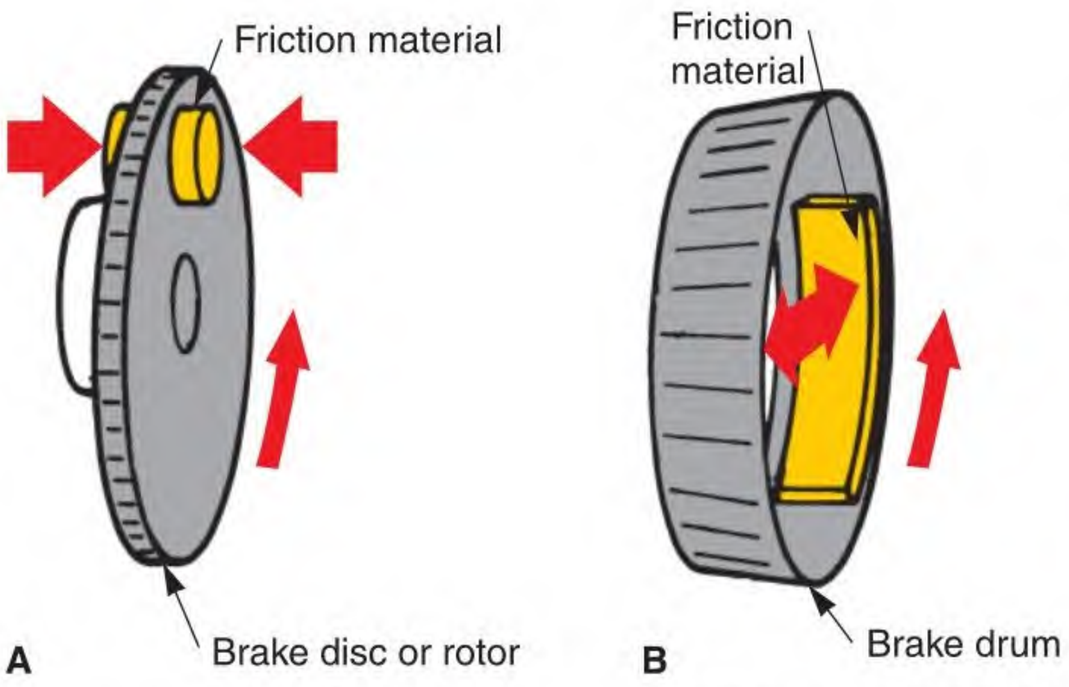
Figure 80-1. These are the basic parts of an automotive brake system. Study them.

- ***Brake pedal assembly***—The brake pedal assembly is a foot lever for operating the master cylinder and power booster. Look at **Figure 80-1**.
- ***Master cylinder***—The master cylinder is a hydraulic-piston pump that develops pressure for the hydraulic brake system.
- ***Brake booster***—The brake booster is a vacuum, electric, or power steering–operated device that assists brake pedal application.
- ***Brake lines and hoses***—Brake lines and hoses are metal tubing and rubber hose that transmit pressure to the wheel brake assemblies.
- ***Wheel brake assemblies***—Wheel brake assemblies are hydraulic-mechanical mechanisms that use hydraulic pressure to produce friction to slow or stop each wheel.
- ***Emergency brakes***, or ***parking brakes***—Emergency brakes are mechanical or electric systems for applying rear brake assemblies.

When the driver pushes on the brake pedal, lever action pushes a rod into the brake booster and master cylinder. This produces hydraulic pressure in the master cylinder. Fluid flows through the brake lines to the wheel brake assemblies. The brake assemblies use this pressure to cause friction for braking.

An emergency brake system uses cables or rods to mechanically apply the rear brakes. This provides a system for holding the wheels when the vehicle is parked on a hill or stopping the vehicle during complete hydraulic brake system failure.

Drum and Disc Brakes



There are two common types of brake assemblies used on modern automobiles: disc brakes and drum brakes. Refer to **Figure 80-2**.

Disc brakes are frequently used on the two front wheels of a vehicle. Drum brakes are often used on the rear wheels. However, disc or drum brakes may be used on all four wheels.

The following are the components of a ***disc brake assembly***:

- ***Caliper***—The caliper is an assembly that holds a hydraulic cylinder, piston, seals, and brake pads.
- ***Caliper cylinder***—The caliper cylinder is a machined hole in the caliper; the piston fits into this cylinder.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 80-2. Compare basic disc brakes and drum brakes. A—Disc brakes are commonly used on the front of the vehicle and sometimes on the rear. B—Drum brakes are normally used on the rear of the vehicle.

- ***Brake pads***—The brake pads are friction members that are pushed against the disc by the action of the master cylinder, caliper cylinder, and piston.
- ***Brake disc***—The brake disc is a large metal ***rotor*** that holds the wheel and tire and uses friction from the brake pads to stop or slow wheel rotation.

The following are the components of a ***drum brake assembly***:

- ***Wheel cylinder assembly***—The wheel cylinder assembly houses a hydraulic piston that is forced outward by fluid pressure.
- ***Brake shoes***—The brake shoes are friction units that are pushed against the rotating brake drum by the action of the hydraulic wheel cylinder.
- ***Brake drum***—The brake drum rubs against the brake shoes to stop or slow wheel rotation.

Braking Ratio

Braking ratio refers to the comparison of front wheel braking effort to rear wheel braking effort. When a vehicle stops, its weight tends to transfer onto the front wheels. The front tires are pressed against the road with greater force. The rear tires lose some of their grip on the road. As a result, the front wheels do more of the braking than the rear.

For this reason, many vehicles have disc brakes on the front and drum brakes on the rear. Disc brakes are capable of producing more stopping effort than drum brakes. If drum brakes are used on both the front and rear wheels, the front shoe linings and drums normally have larger surface areas than the rear linings and drums.

Typically, front wheel brakes handle 60%–70% of the braking power. Rear wheel brakes handle 30%–40% of the braking. Front-wheel-drive cars, having even more weight on the front wheels, can have even a higher braking ratio at the front wheels.

Brake System Hydraulics

A ***hydraulic system*** is basically a system that uses a liquid to transmit motion or pressure from one point to another. Modern brake systems are hydraulic. They use a confined brake fluid to transfer brake pedal motion and pressure to each of the wheel brake assemblies.

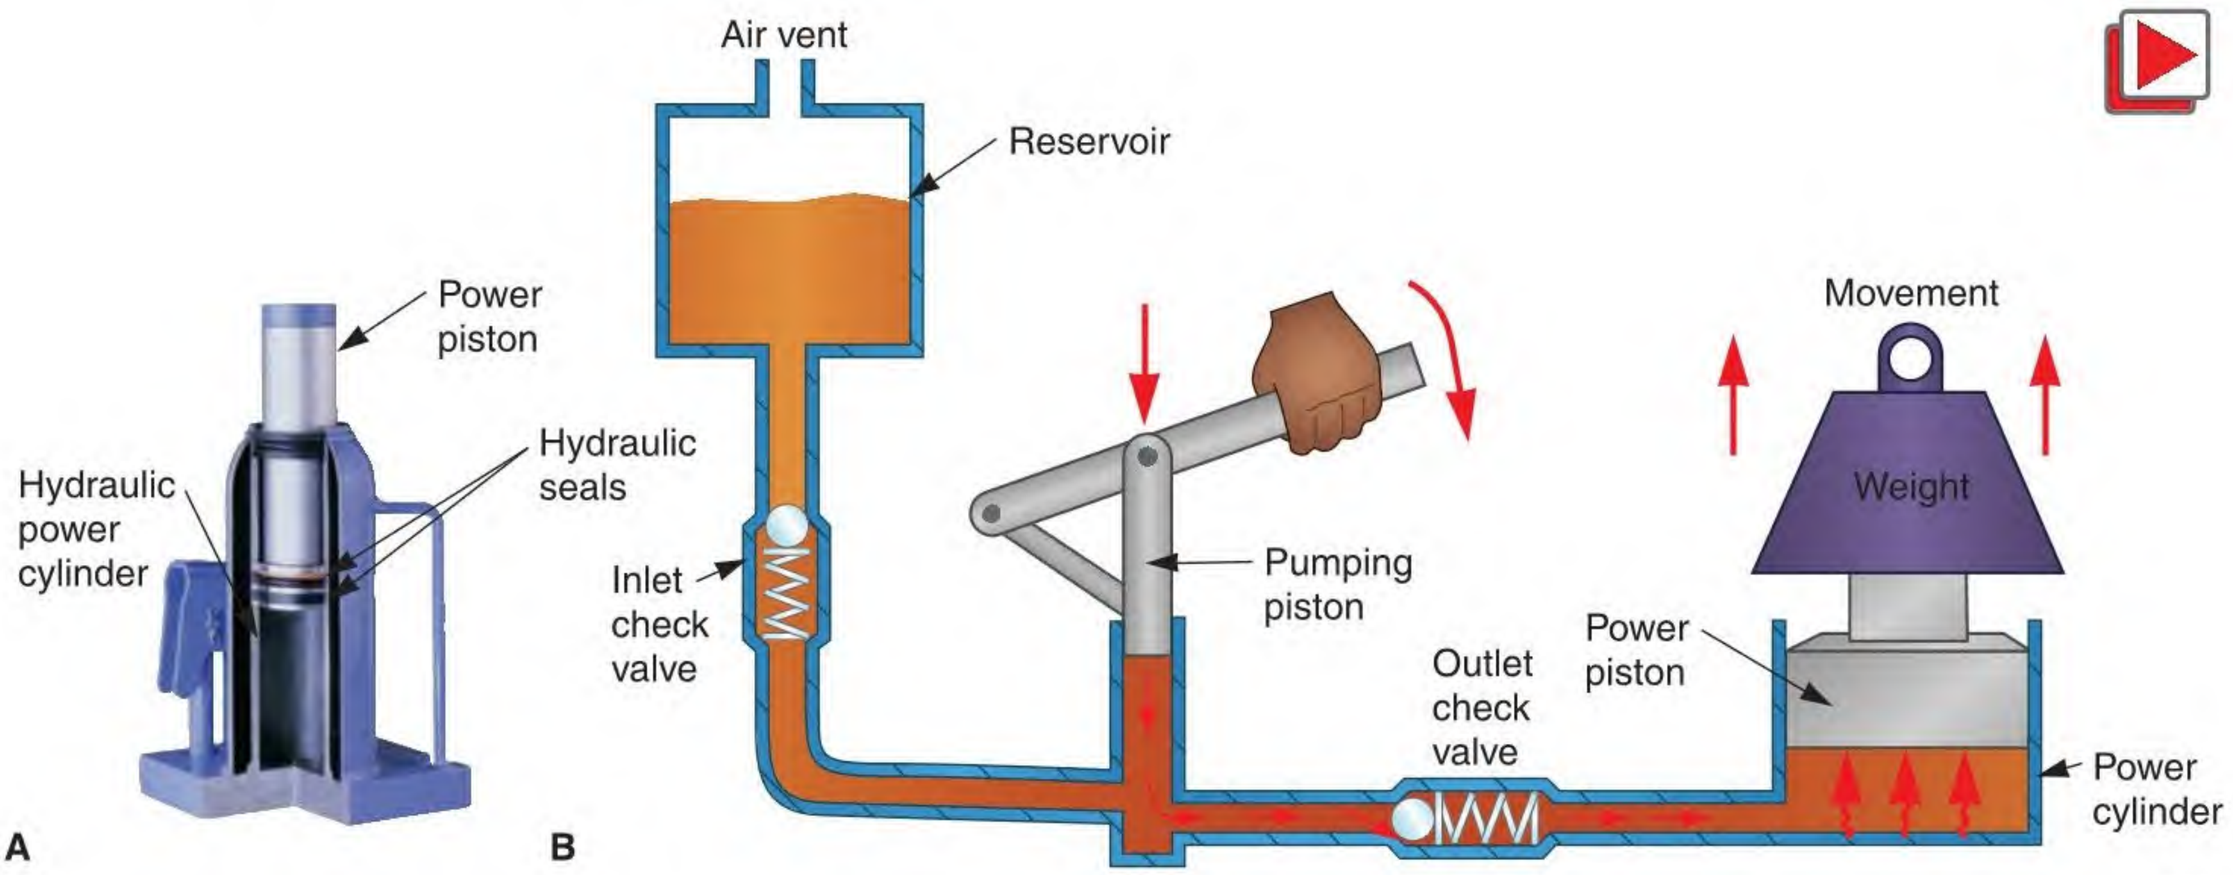
Several principles apply to the operation of a hydraulic system. These include:

- Liquids in a confined area will not compress. However, air in a confined area will compress.
- When pressure is applied to a closed system, pressure is exerted equally in all directions.
- A hydraulic system can be used to increase or decrease force or motion.

Hydraulic System Action

Suppose two cylinders of equal diameter are placed side by side with a tube connecting them. The system is filled with liquid. Each cylinder contains a piston. If you push down on one of the pistons, the other piston will move an equal distance and with equal force.

Since the liquid will not compress and the cylinders are the same diameter, the same amount of liquid, pressure, and motion is transferred from one cylinder to the other.



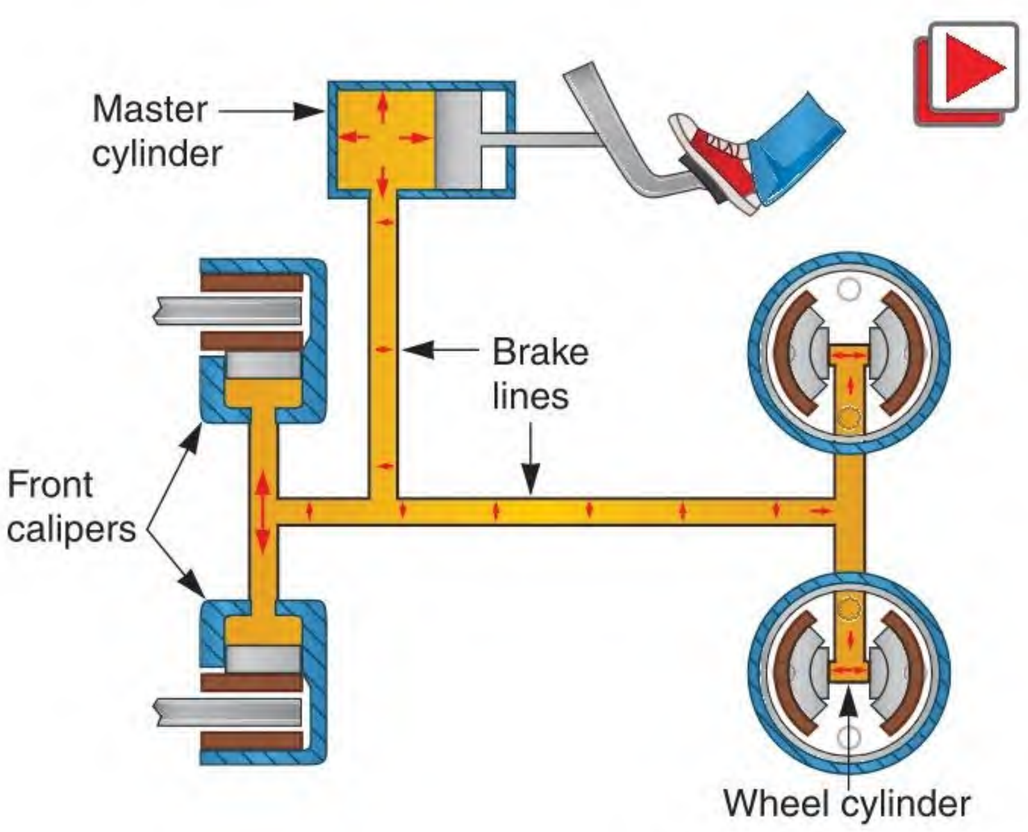
When pistons of different sizes are used, motion and force can be increased or decreased. Suppose a small piston acts on a larger piston. The larger piston will move with more force. However, it will move a shorter distance.

When a large diameter piston acts on a smaller piston, the opposite is true. The smaller piston slides farther in its cylinder than the large piston, but it moves with less force.

A simple hydraulic jack demonstrates the principles just discussed. Look at **Figure 80-3**.

Applying these hydraulic principles to a brake system, you can see how stopping force is transmitted from the master cylinder to each wheel brake assem-

Copyright Goodheart-Willcox Co., Inc.



OTC

Figure 80-3. A hydraulic jack and a brake system use many of the same operating principles. A—Cutaway view shows how oil under pressure is used to raise the hydraulic jack when the handle is pumped. B—This drawing of a hydraulic jack demonstrates how a small piston acting on a large piston can increase force tremendously. Study how the check valves only allow oil flow in one direction.

bly. The master cylinder acts as the pumping piston that supplies system pressure. The wheel cylinder acts as the power piston, moving the friction linings into contact with the rotating drums or discs, **Figure 80-4**.

Brake System Components

It is important for you to know the location and construction of major brake system components. This will better prepare you to troubleshoot and repair these important parts.

Goodheart-Willcox Publisher

Figure 80-4. Like a basic hydraulic jack, the master cylinder acts as a pumping piston to move the pistons at the wheel brake assemblies.

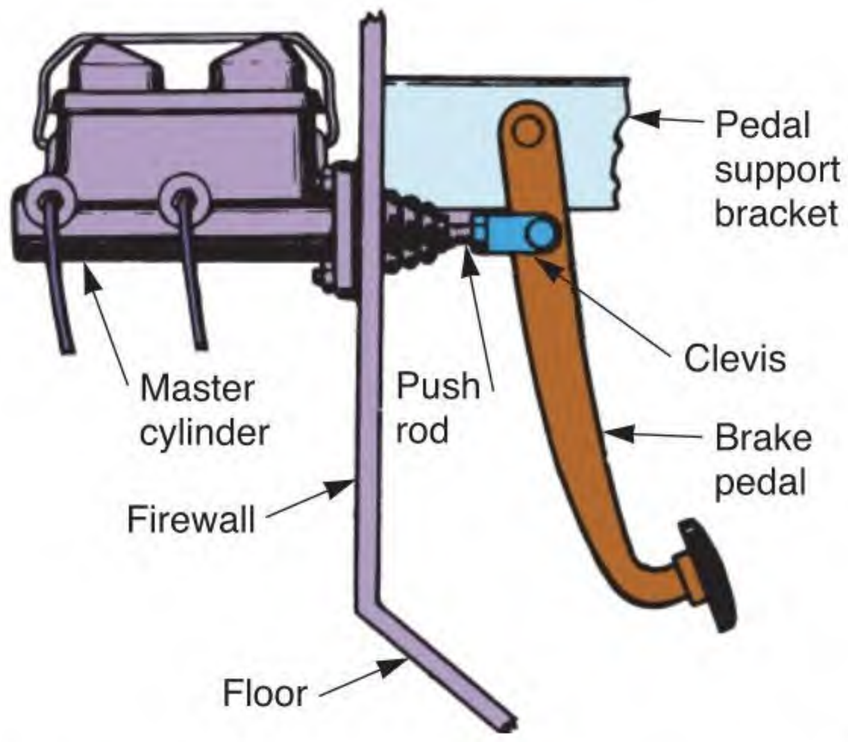
Brake Pedal Assembly

The brake pedal assembly is a lever arm to increase the force applied to the master cylinder piston. A manual master cylinder bolts directly to the engine's firewall. The brake pedal assembly bolts under the dash, **Figure 80-5**.

The pedal swings on a hinge in the pedal support bracket. A push rod connects the brake pedal to the master cylinder piston.

Master Cylinder

A master cylinder is a foot-operated pump that forces fluid into the brake lines and wheel cylinders. Refer to **Figure 80-6**.



A master cylinder can have four basic functions:

- It develops pressure, causing the wheel cylinder pistons to move toward the discs or drums.
- After all the shoes or pads produce sufficient friction, it helps equalize the pressure required for braking.
- It keeps the system full of fluid as the brake linings wear.
- It can maintain a slight pressure to keep contaminants (air and water) from entering the system.

Master Cylinder Construction

In its simplest form, a master cylinder consists of a housing, reservoir, piston, rubber cup, return spring, and rubber boot. A cylinder is precision machined in

Copyright Goodheart-Willcox Co., Inc.

Bendix

Figure 80-5. The brake pedal assembly bolts under the dash. A push rod transfers pedal movement into the master cylinder and operates the piston in the master cylinder.

the housing of the master cylinder. The spring, cup, and metal piston slide in this cylinder. Two ports are drilled between the reservoir and cylinder.

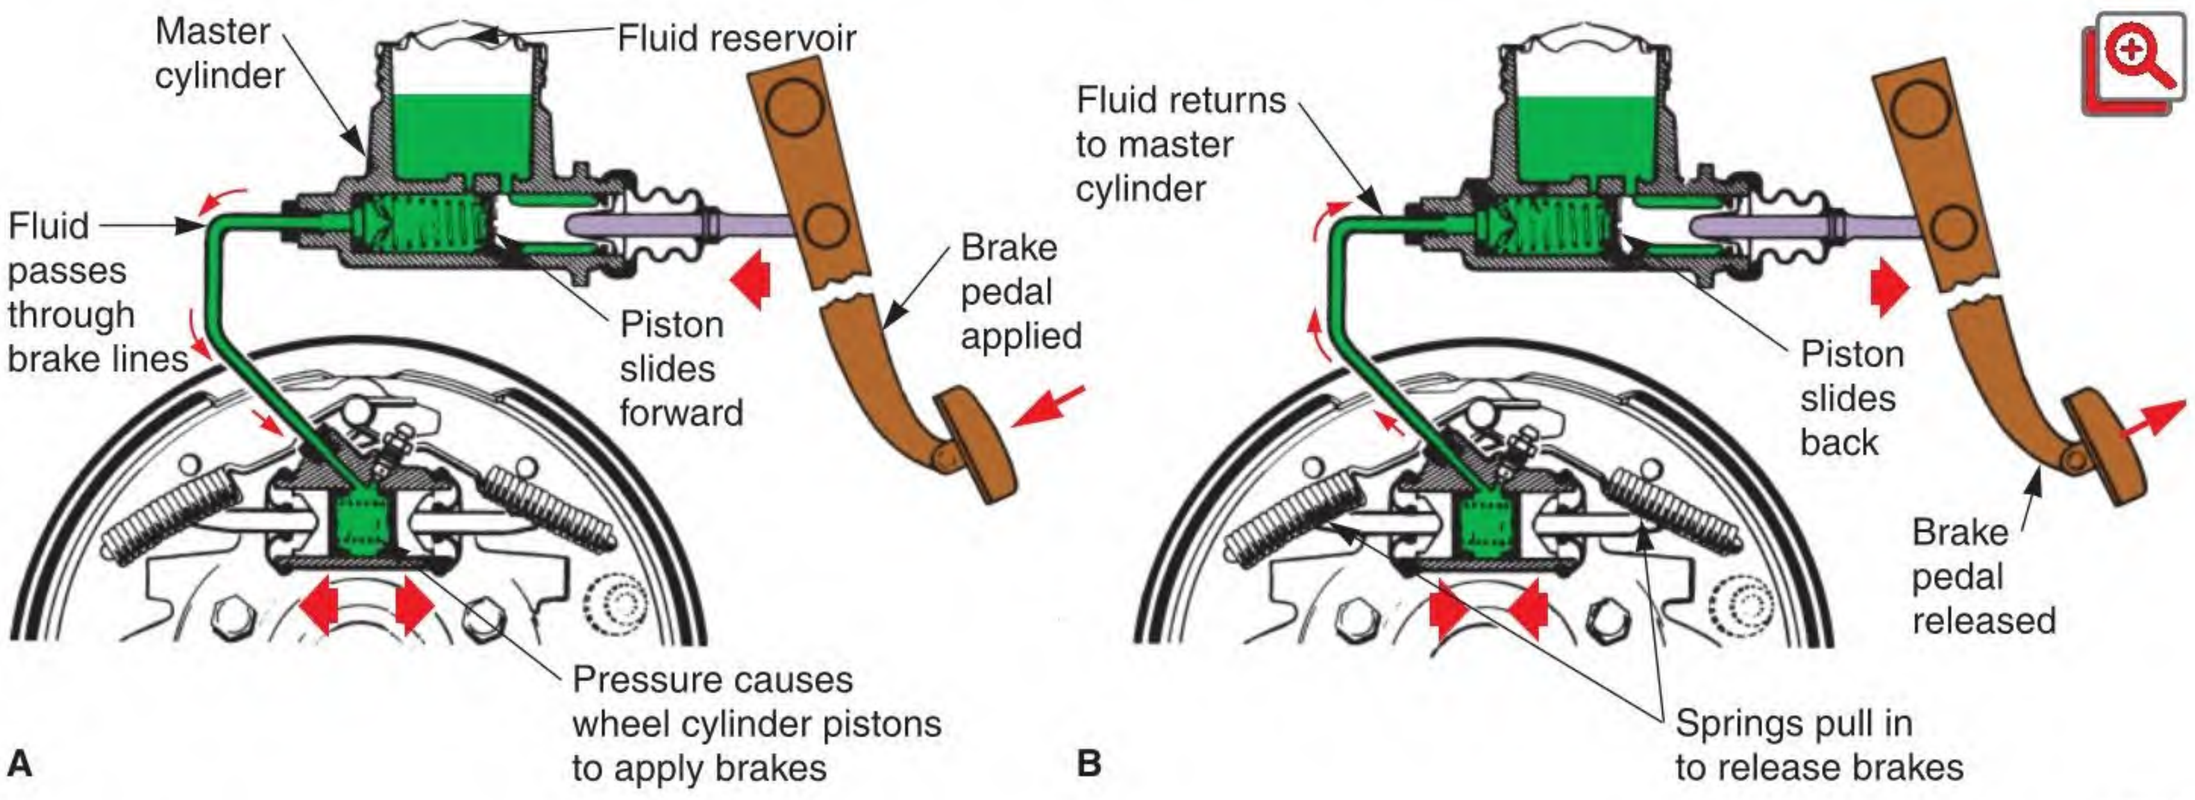
The ***cup*** and ***piston*** in the master cylinder are used to pressurize the brake system. When they are pushed forward, they trap the fluid, building pressure.

The master cylinder ***intake port***, or vent, allows fluid to enter the rear of the cylinder as the piston slides forward. Fluid flows out of the reservoir, through the intake port, and into the area behind the piston and cup.

Then, when the brake pedal is released, the return spring forces the piston and cup back in the cylinder. If needed, the rubber cup flexes forward, allowing fluid to enter the area in front of the piston and cup. Small holes are drilled in the edge of the piston so that fluid can flow past the cup. See **Figure 80-7**.

The ***compensating port*** releases extra pressure when the piston returns to the released position. Fluid can flow back into the reservoir through the compensating port. The action of the intake port and the compensating port keep the system full of fluid.

Residual pressure valves maintain residual fluid pressure of approximately 10 psi (69 kPa) to help keep contaminants out of the system. One valve is located in each outlet to the brake lines, **Figure 80-8**.



The ***rubber boot*** prevents dust, dirt, and moisture from entering the back of the master cylinder. The boot fits over the master cylinder housing and the brake pedal push rod.

The ***master cylinder reservoir*** stores an extra supply of brake fluid. The reservoir may be cast as part of the housing, or it may be a removable plastic part. Today's reservoirs normally have two sections, or compartments.

Dual Master Cylinder

Older vehicles used single-piston, single-reservoir master cylinders. However, they were dangerous. If a brake fluid leak developed (line rupture, seal damage, crack in brake hose), a sudden loss of braking ability could occur. Modern vehicles use a dual master cylinder for added safety, **Figure 80-9**.

The ***dual master cylinder***, also called the ***tandem master cylinder***, has two separate hydraulic

FMC

Figure 80-6. This single-piston master cylinder demonstrates the simplified action of a brake system. A—Application of pedal moves push rod into piston. Master cylinder piston pressurizes fluid in cylinder and line. Pressure pushes wheel cylinder pistons apart and brakes are applied. B—Release of brake pedal allows retracting springs to pull brake shoes away from brake drum. Fluid flows back through line and into master cylinder.

Copyright Goodheart-Willcox Co., Inc.

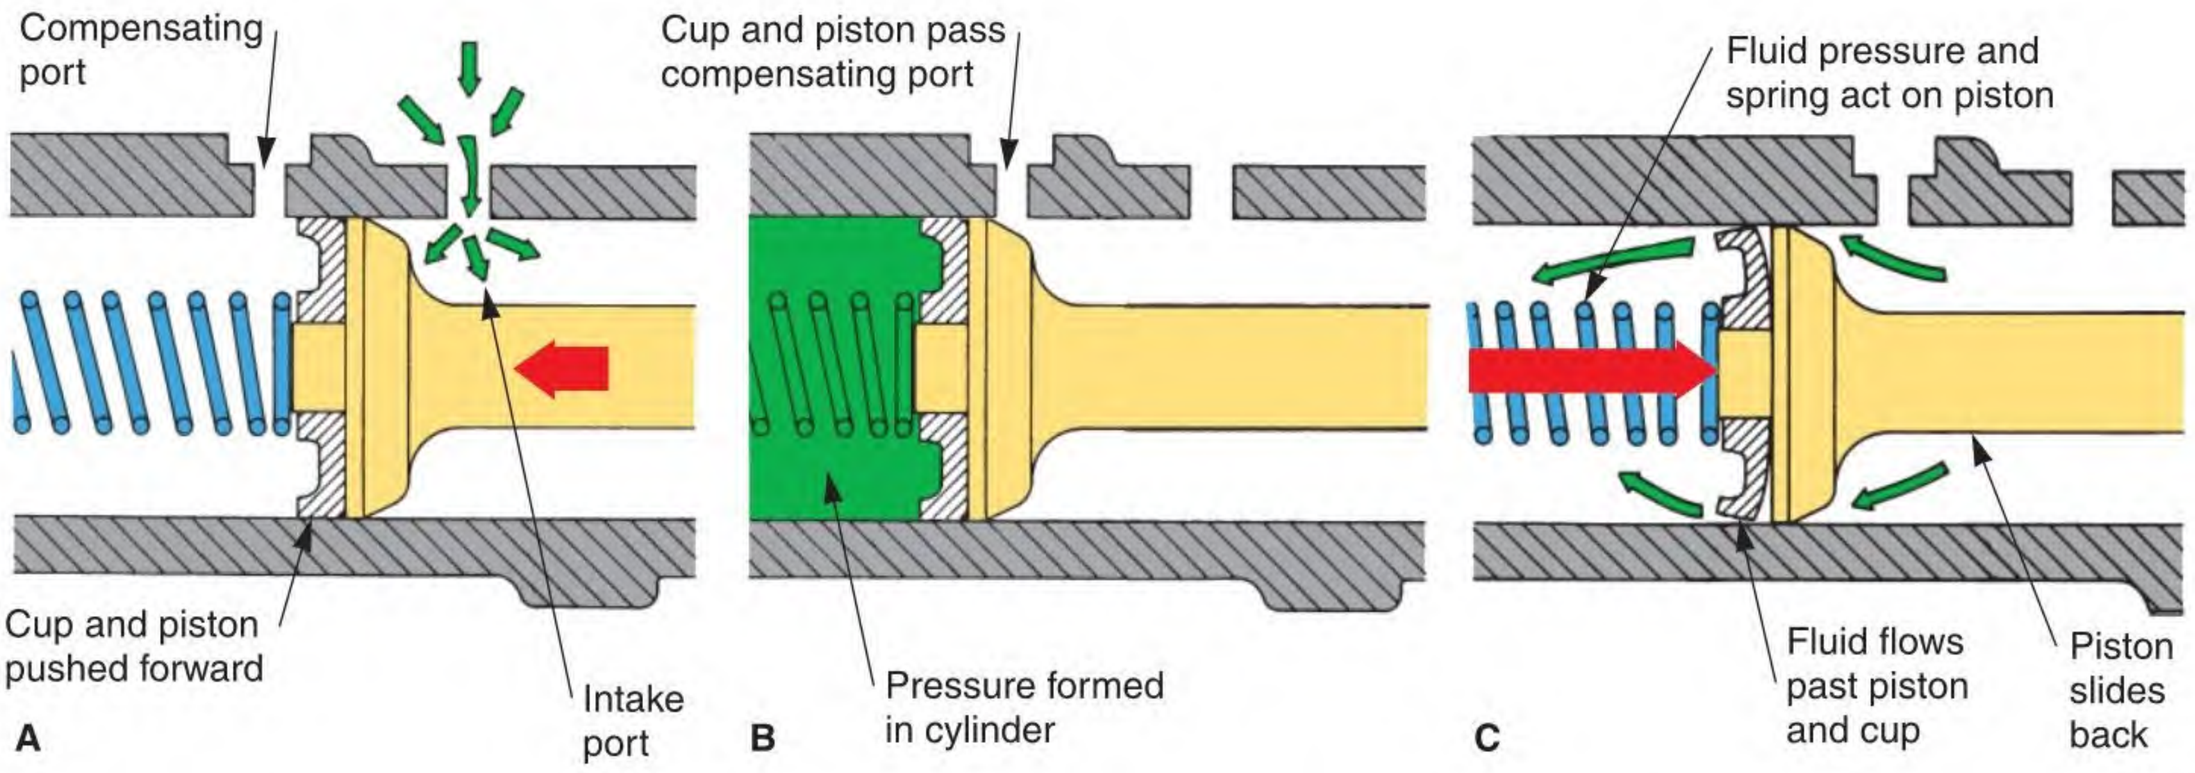


Figure 80-7. Note piston and cup action inside the master cylinder. A—Piston slides forward. Fluid flows into the area behind the piston. Excess fluid flows into the reservoir through the compensating port. B—Piston and cup move past the compensating port, and pressure forms in the front section of the cylinder to apply the brakes. C—When the brake pedal is released, the cup flexes forward so that fluid can flow to the front of the piston for release of the brakes.

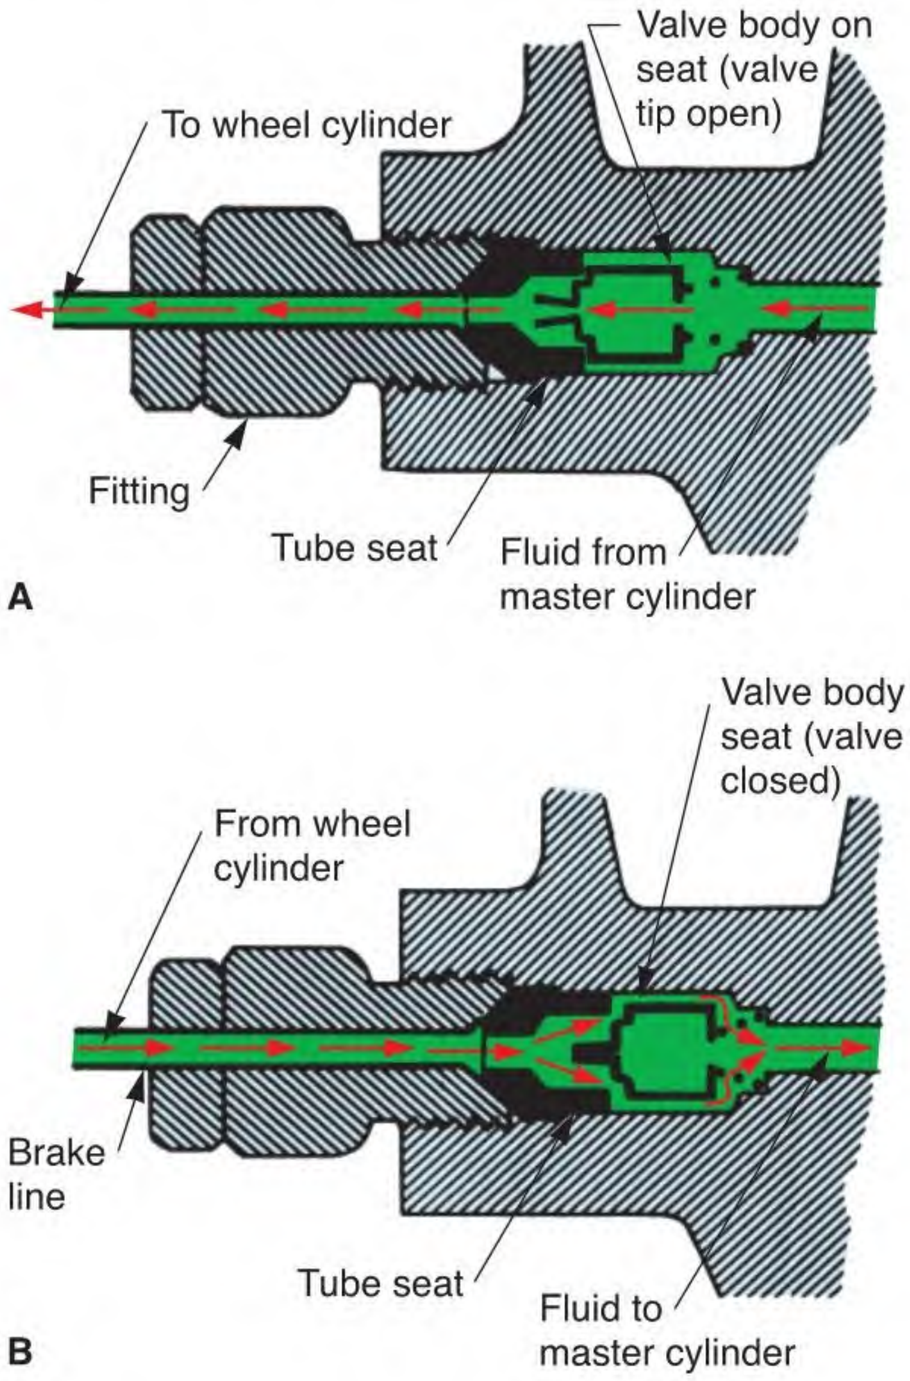

Figure 80-8. Residual pressure valves maintain some line pressure after the brakes are released. This helps keep air out of the system. A—When the brakes are applied, fluid flows freely through the valve. B—After the brakes are released, the valve closes to restrict the return of fluid to the master cylinder.

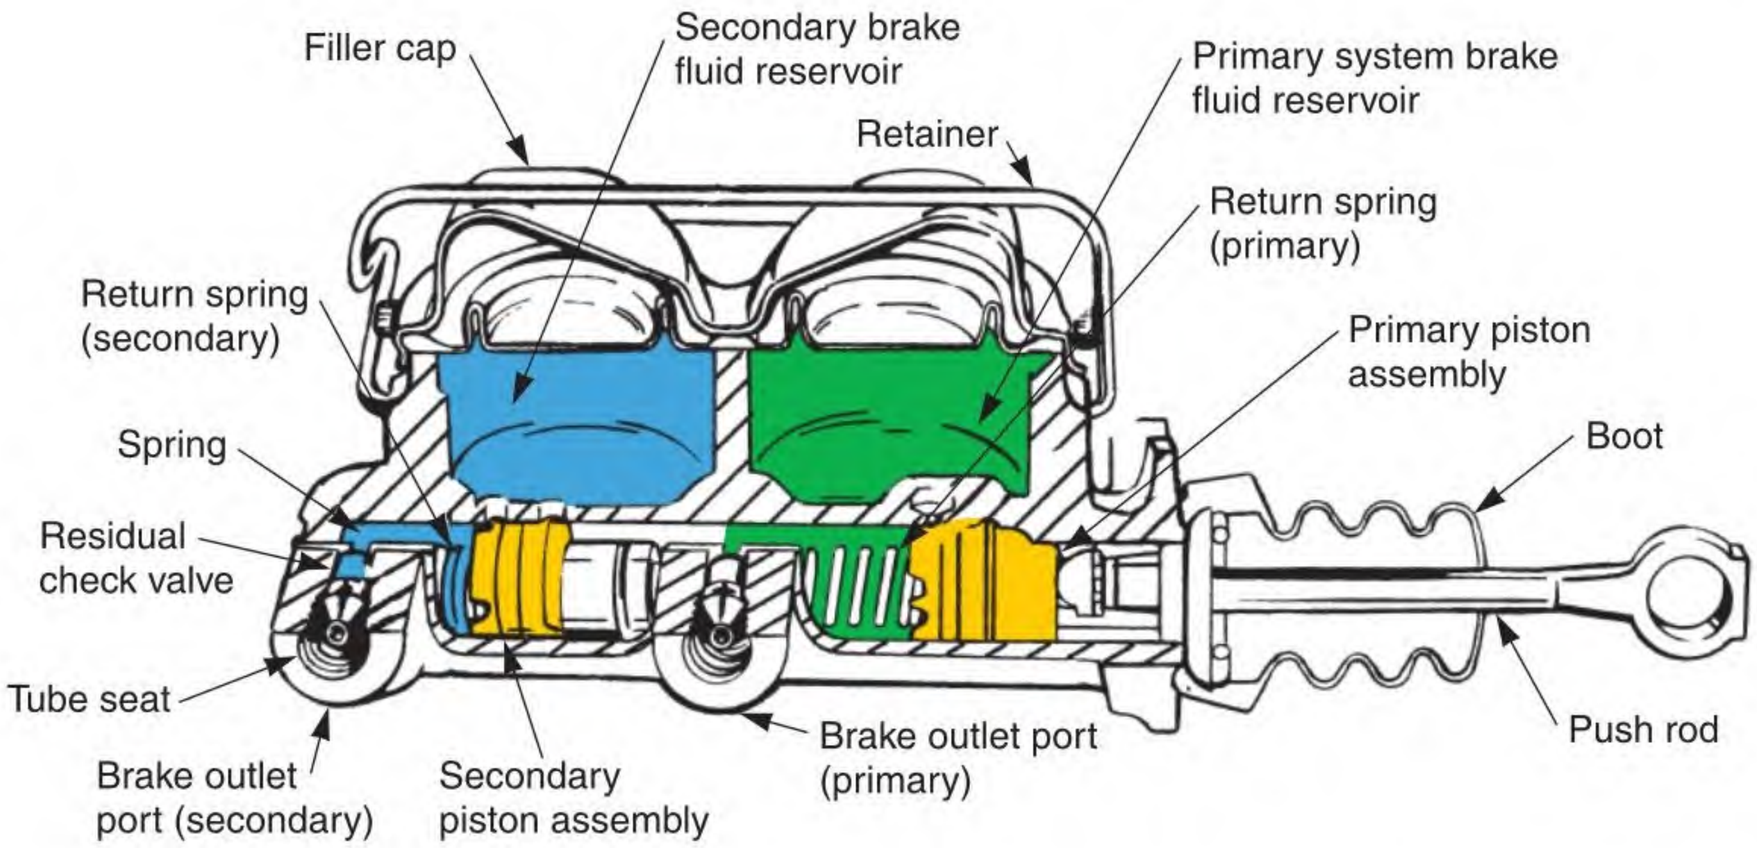
pistons and two fluid reservoirs. Each piston operates a hydraulic circuit that controls two wheel brake assemblies. Then, if there is a system leak in one of the hydraulic circuits, the other circuit can still provide braking action on two wheels. See **Figure 80-10**.

In the dual master cylinder, the rear piston assembly is called the ***primary piston***. The front piston is termed the ***secondary piston***.

Dual Master Cylinder Operation

The action of the pistons, cups, and ports in the dual master cylinder is similar to the action of those used in a single-piston unit. See **Figure 80-11A**.



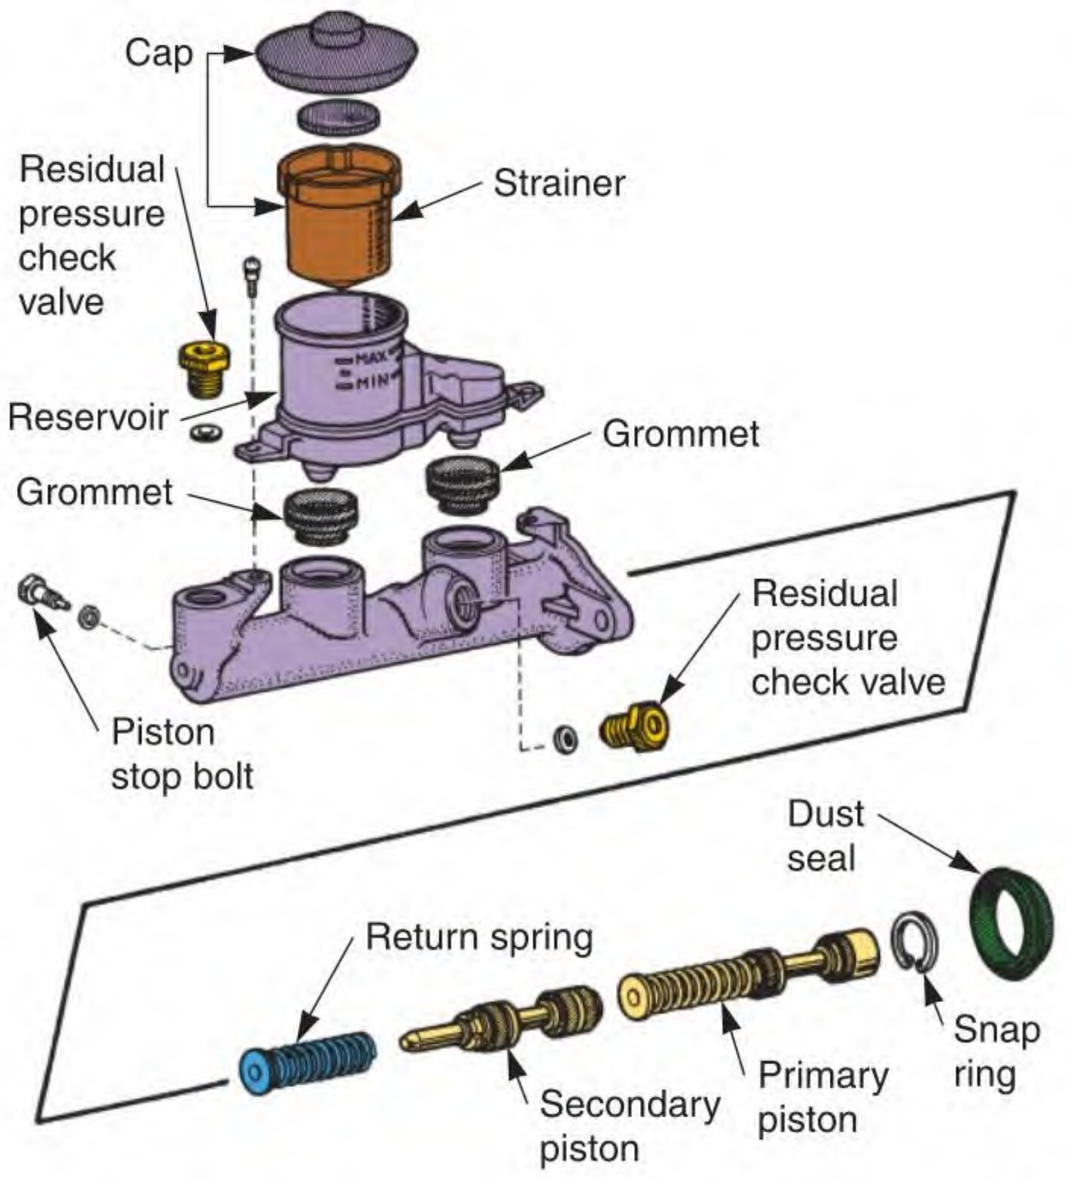
When both systems are intact (no fluid leaks), each piston produces and supplies pressure to two wheel cylinders (all four wheel brake assemblies are applied).

If there is a pressure loss in the primary section of the brake system (rear section of master cylinder), the primary piston slides forward and pushes on the secondary piston. This forces the secondary piston forward mechanically, building pressure in two of the wheel brake assemblies, as shown in **Figure 80-11B**.

When a brake line, wheel cylinder, or other component leaks in the secondary circuit (parts fed by secondary piston), the secondary piston slides completely forward in the cylinder. Then, the primary piston provides hydraulic pressure for the other two brake assemblies. See **Figure 80-11C**.

It is very unlikely that both systems would fail at the same time. If they did, the mechanical parking brake would be needed to slow and stop the vehicle.

Copyright Goodheart-Willcox Co., Inc.



Delco

Figure 80-9. Dual master cylinders are now used because they will still provide braking action when a major hydraulic leak develops. With single-piston master cylinder, a leak could cause sudden and complete loss of brakes.

Power Brakes

Power brakes use a booster and either engine vacuum, electric pump, or hydraulic pressure to assist brake pedal application. The booster (assisting mechanism) is located between the brake pedal linkage and the master cylinder. When the driver presses the brake pedal, the brake booster helps push on the piston.

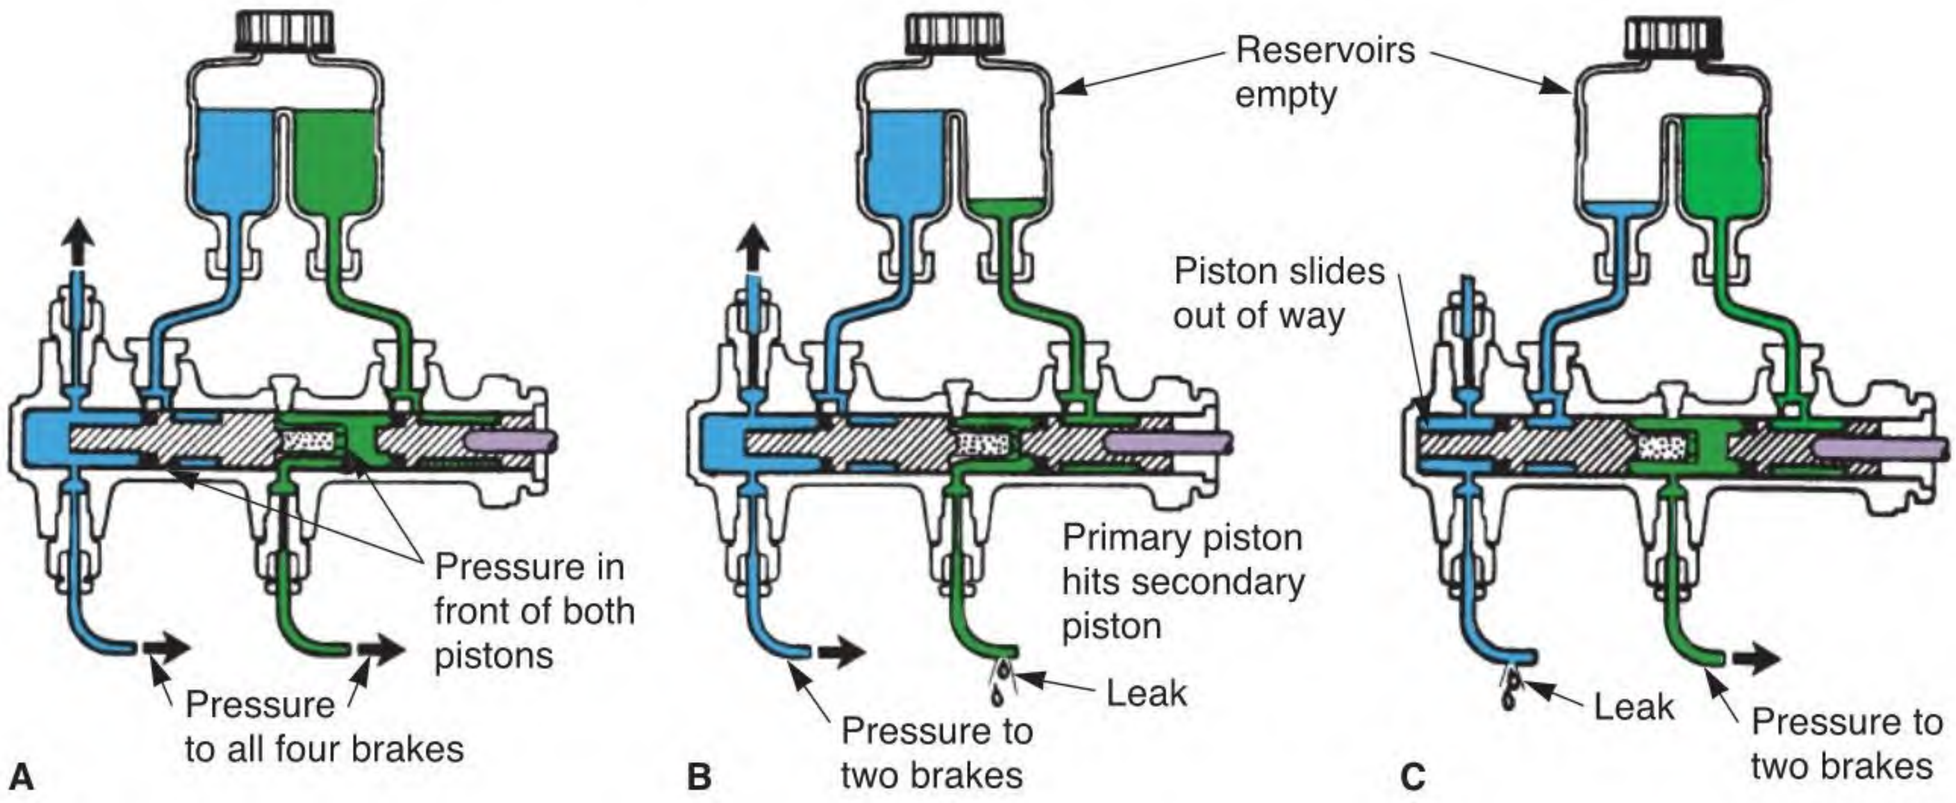
Toyota

Figure 80-10. Note the major parts of this modern dual master cylinder.

Power Brake Vacuum Boosters

A power brake ***vacuum booster*** uses engine vacuum (or vacuum created by a separate pump on diesel engines) to apply the hydraulic brake system. The principles of a vacuum booster are shown in **Figure 80-12**.

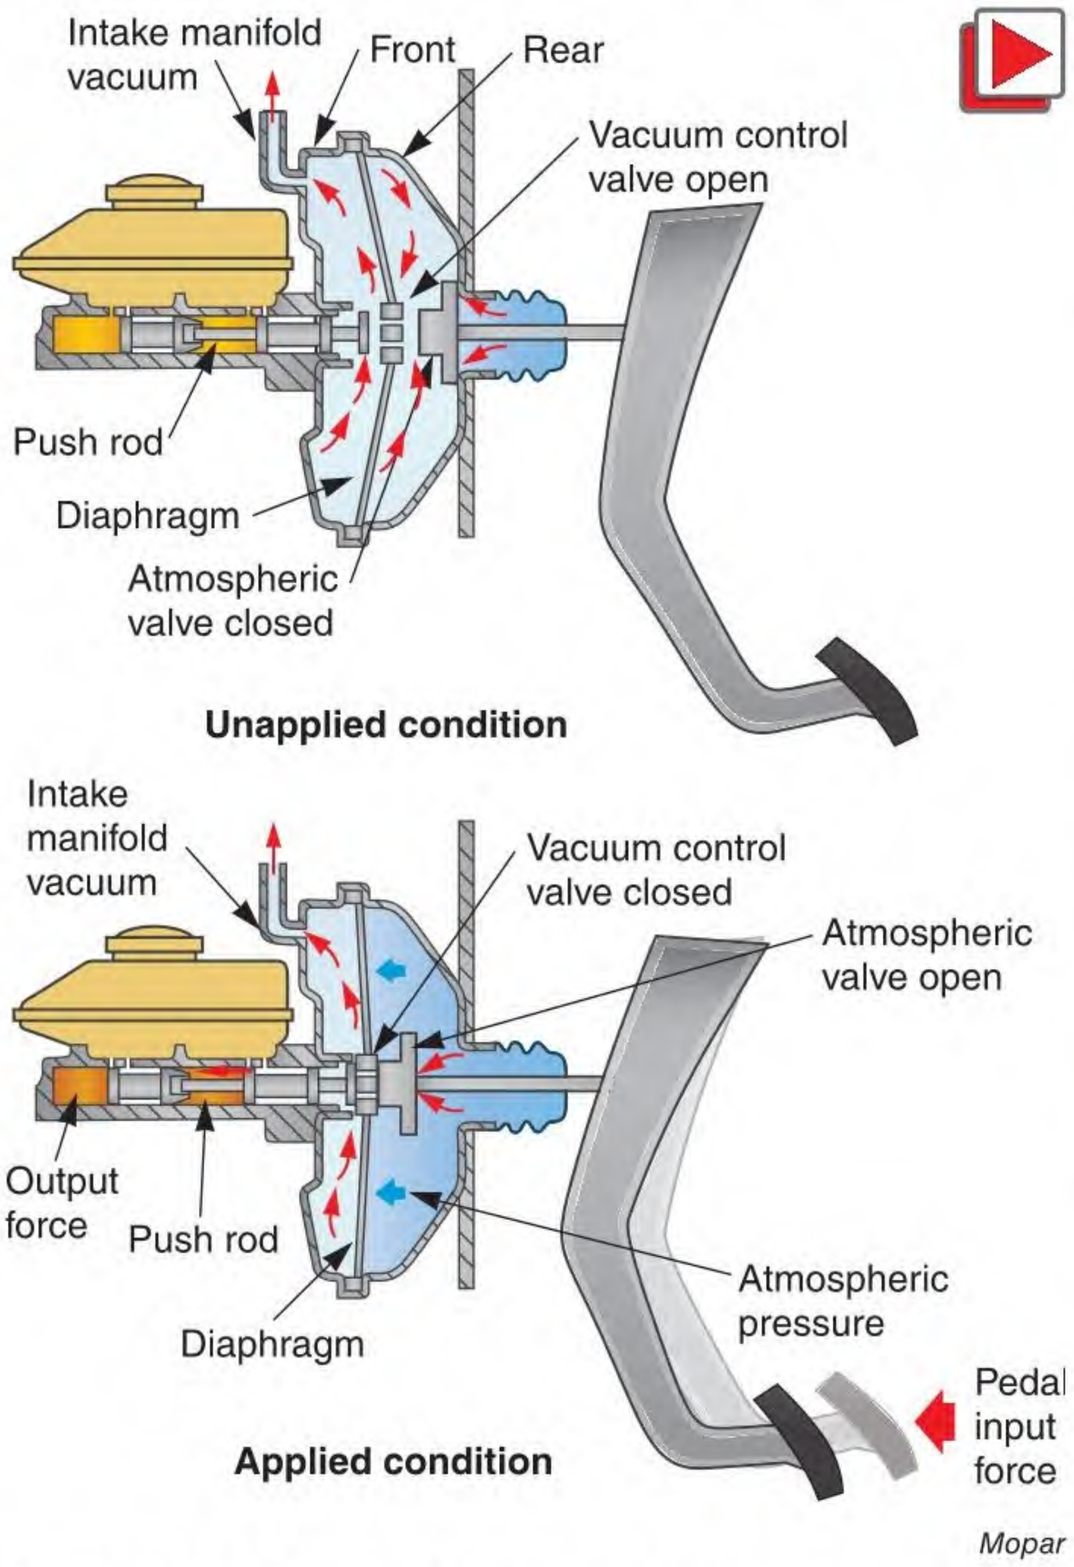
A vacuum booster basically consists of a cylindrical housing that encloses a diaphragm or a piston. When vacuum is applied to one side of the booster, the piston or diaphragm moves toward the low-pressure area. This movement is used to help force the piston into the master cylinder.



Vacuum Booster Types

There are two general types of vacuum brake boosters: atmospheric suspended boosters and vacuum suspended boosters.

An ***atmospheric suspended brake booster*** has atmospheric pressure (normal air pressure) on both sides of the diaphragm or piston when the brake pedal is released. As the brakes are applied, a vacuum is formed on one side of the booster. Atmospheric pressure then pushes on and moves the piston or diaphragm.



A ***vacuum suspended brake booster*** has vacuum on both sides of the piston or diaphragm when the brake pedal is released. Pushing down on the

Figure 80-11. Study the operation of this dual master cylinder. A—No problem in the brake system. Both pistons produce pressure for all four wheel brake assemblies. B—The rear brake circuit is leaking. The primary piston pushes on the secondary piston, and two wheel brake assemblies still work to stop vehicle. C—With a front brake circuit leak, the secondary piston slides forward in the cylinder. The primary piston then operates normally to apply two wheel brake assemblies.

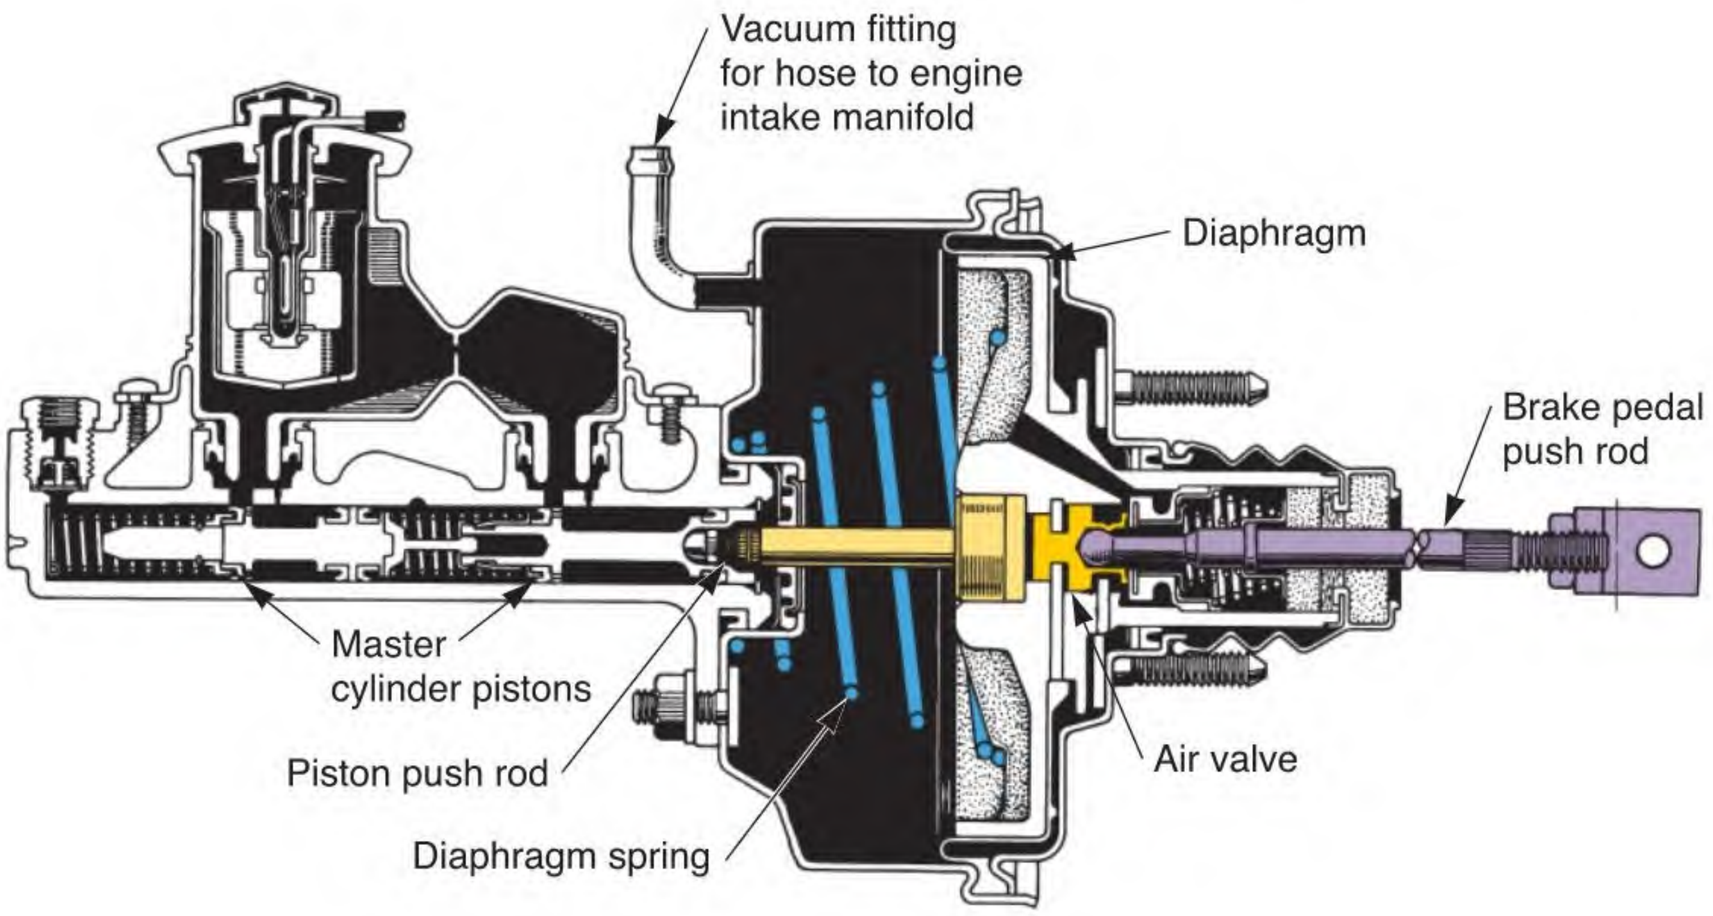
Mopar

Figure 80-12. A vacuum booster uses engine vacuum or vacuum created by an auxiliary pump to help apply the brake pedal. The vacuum acts on a diaphragm, which pushes on a push rod.

brake pedal releases the vacuum on one side of the booster. The difference in pressure pushes the piston or diaphragm for braking action. See **Figures 80-13**.

Power Brake Hydraulic Boosters

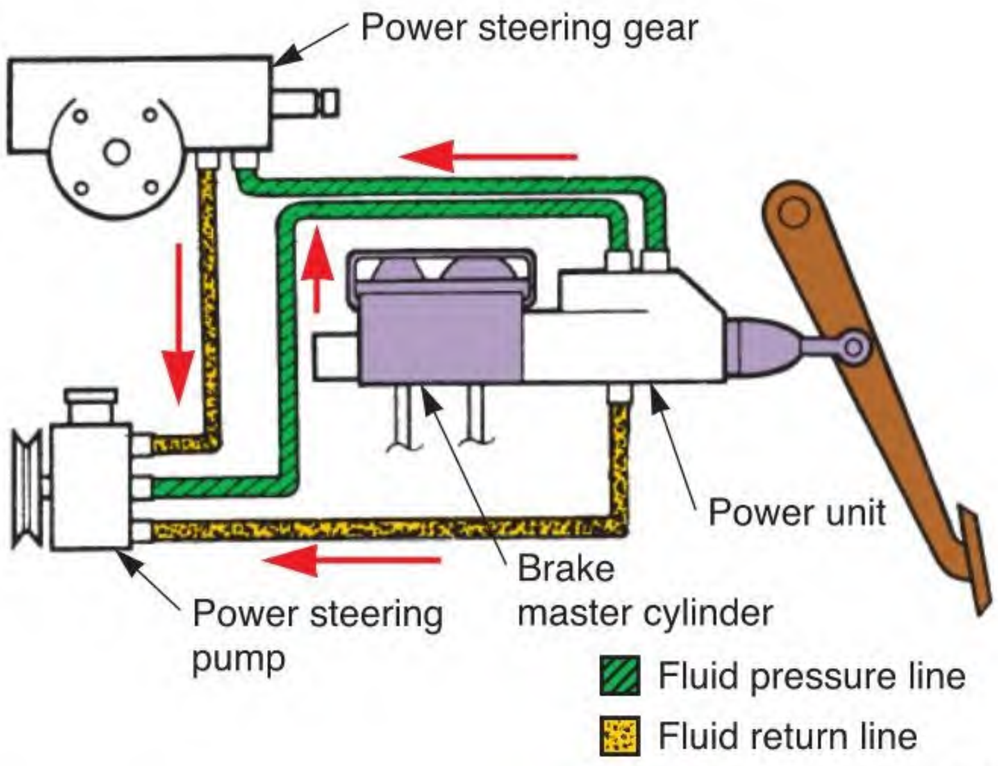
A power brake ***hydraulic booster*** uses power steering pump pressure to help the driver apply the brake pedal. Sometimes called ***hydro-boost*** or ***hydra-booster***, it uses fluid pressure, instead of vacuum, to help force the piston forward, **Figure 80-14**.



Hydro-boost power brakes are commonly used on vehicles equipped with diesel engines. A diesel engine does not produce enough intake manifold vacuum to operate a vacuum booster. The power steering pump becomes an excellent source of energy to assist brake application. Some gasoline engine-powered vehicles also use this setup. Refer to **Figure 80-15**.

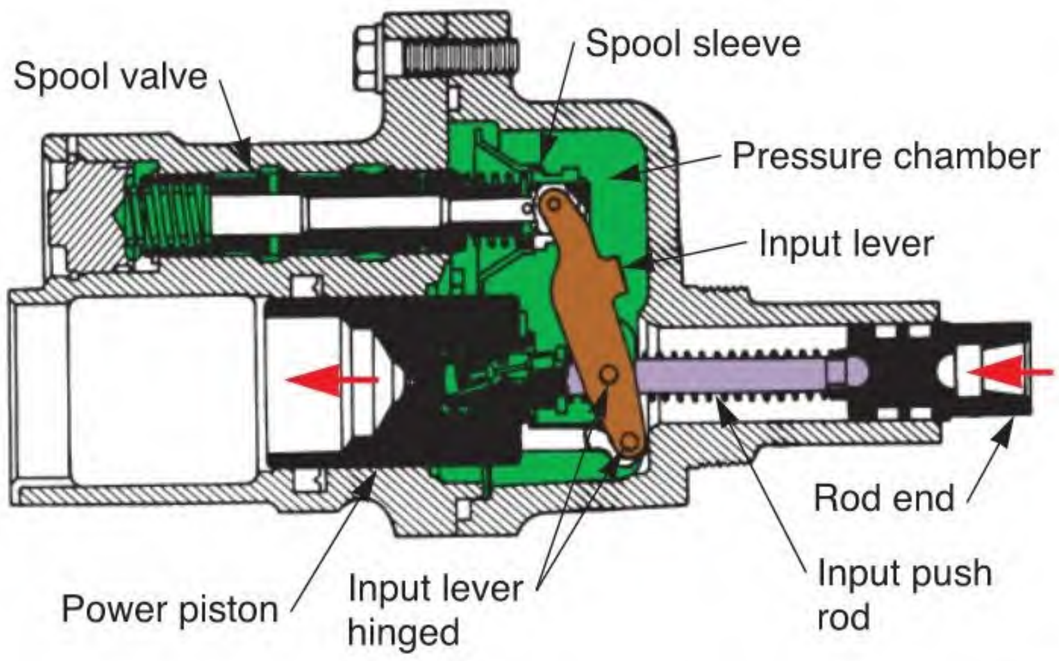
Brake Fluid

Brake fluid is a specially blended hydraulic fluid that transfers pressure to the wheel brake assemblies. Brake fluid is one of the most important components of a brake system because it ties all the other components into a functioning unit.



Automakers recommend brake fluid that meets or exceeds SAE (Society of Automotive Engineers) and DOT (Department of Transportation) specifications. Only brake fluid that satisfies their requirements should be used.

Copyright Goodheart-Willcox Co., Inc.



Toyota

Figure 80-13. Study the internal parts of this brake booster and master cylinder.

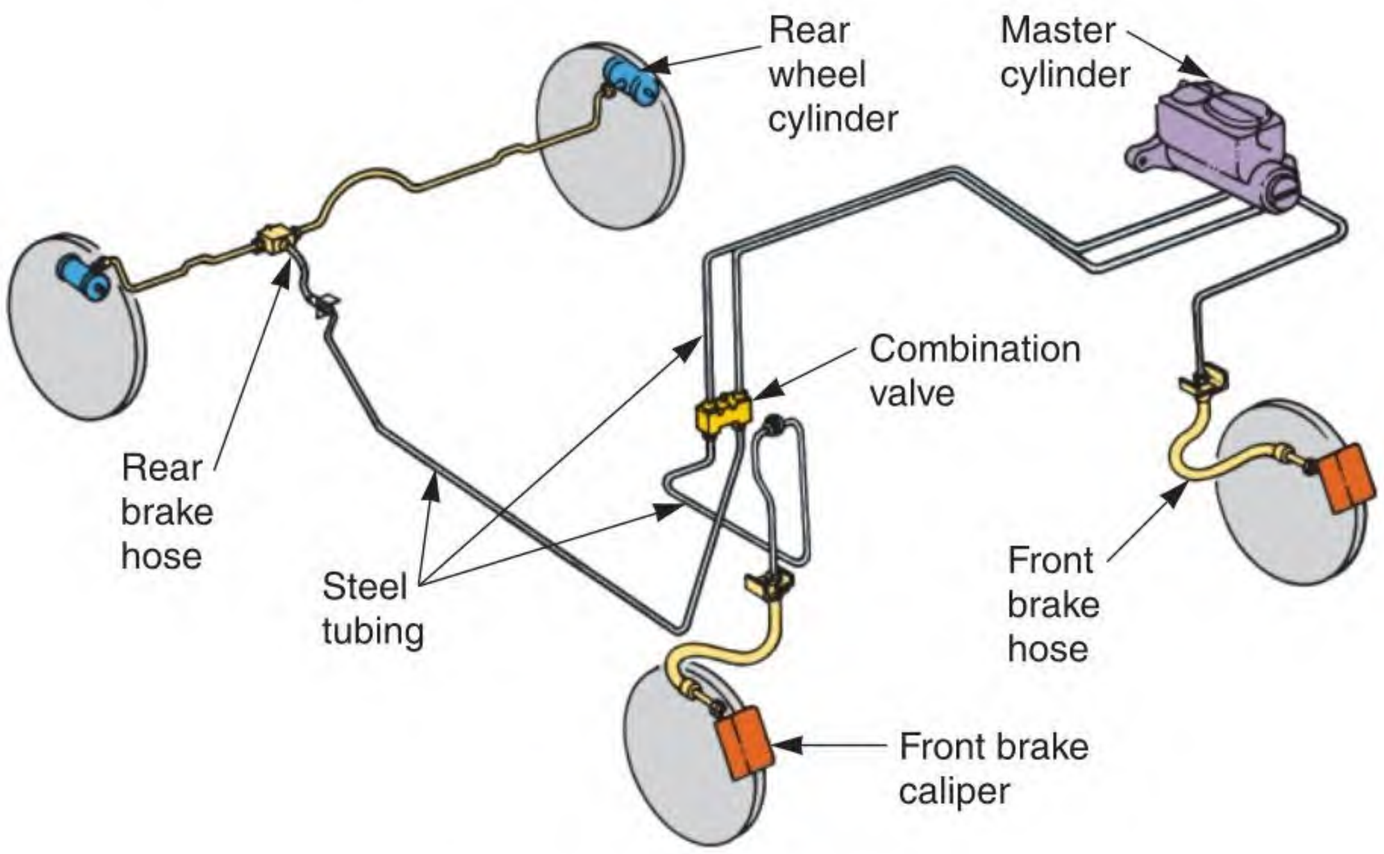
FMC

Figure 80-14. A hydraulic brake booster uses oil pressure from the power steering pump.

FMC

Figure 80-15. Cutaway view shows the inside of a hydraulic brake booster. When the pedal pushes on the unit, the spool valve allows more oil to enter the pressure chamber. This causes the power piston to act on the master cylinder to provide power assist.

Brake fluid must have the following characteristics:

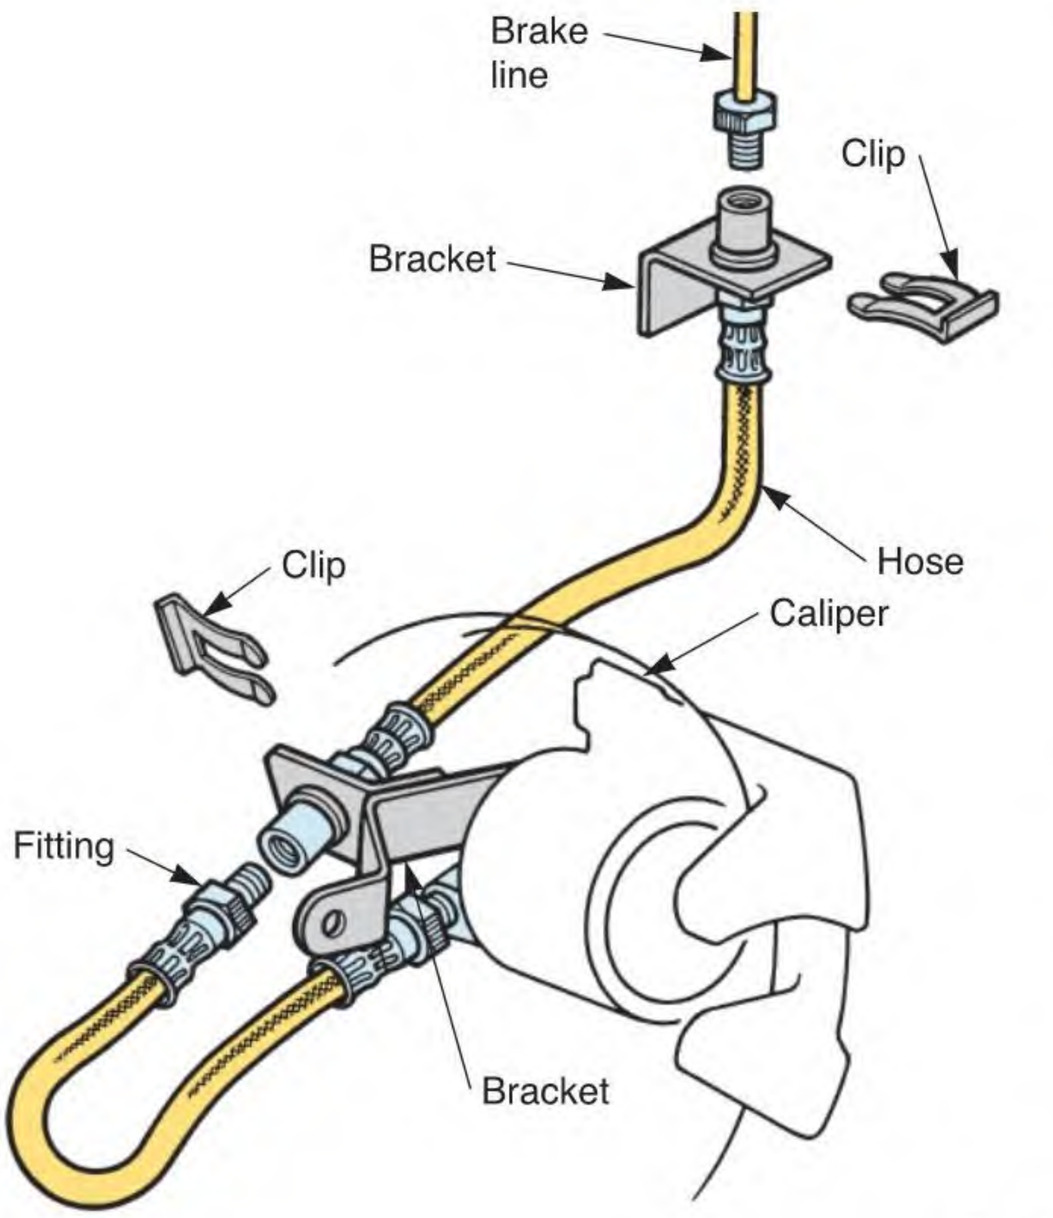


- Maintain correct viscosity—Brake fluid is free flowing at all temperatures.
- High boiling point—Brake fluid remains liquid at highest system operating temperature.
- Noncorrosive—Brake fluid does not attack metal or rubber brake system parts.
- Water tolerant—Brake fluid absorbs moisture that collects in the system.
- Lubricates—Brake fluid reduces wear of the pistons and cups.
- Low freezing point—Brake fluid does not freeze in cold weather.

Brake Lines and Hoses

Brake lines and ***brake hoses*** transfer fluid pressure from the master cylinder to the wheel brake assemblies. Look at **Figure 80-16**.

Brake lines are made of double-wall steel tubing and usually have double-lap flares on their ends to prevent high pressure leakage.



Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 80-16. Note the routing and location of metal brake lines and flexible hoses. Hoses are needed because suspension movement would break steel tubing.

Brake hoses are reinforced braided rubber hydraulic hoses with threaded metal end fittings. Hoses are used where a flexing action is needed. For instance, brake hose is used between the frame and the front caliper cylinders. This allows the wheels to move up and down or from side to side without brake line damage. Refer to **Figure 80-17**.

Toyota

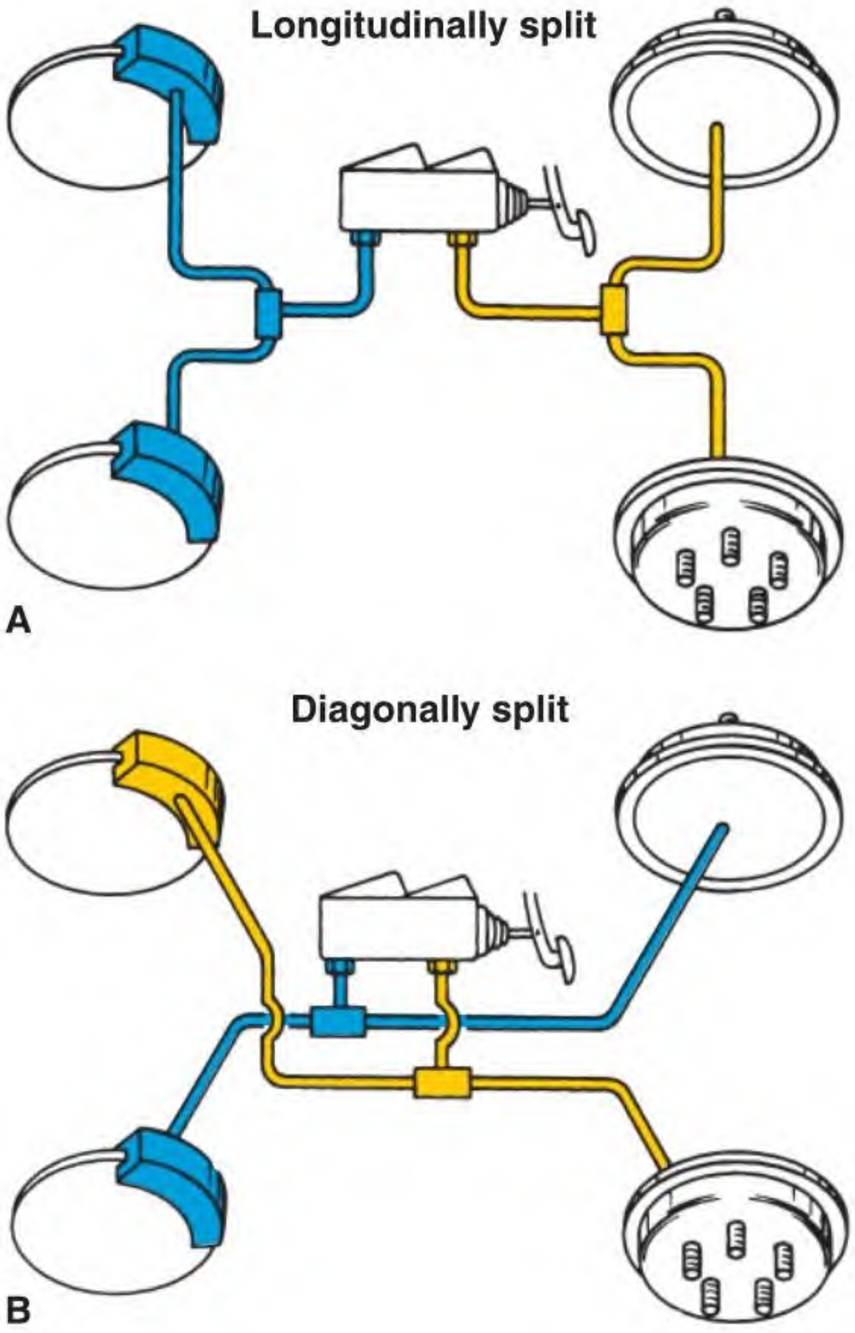
Figure 80-17. Brackets and clips are used to secure the brake hoses and lines to the frame or body. Lines must not be allowed to vibrate or they can fatigue and break.

A junction block is used where a single brake line must feed two wheel cylinders. It is simply a hollow fitting with one inlet and two or more outlets.

In a ***longitudinally split*** (front to rear) brake system, one master cylinder piston operates the front wheel brake assemblies and the other operates the rear brake assemblies. See **Figure 80-18A**.

A ***diagonally split*** (corner to corner) brake system has each master cylinder piston operating the brake assemblies on opposite corners of the vehicle, **Figure 80-18B**.

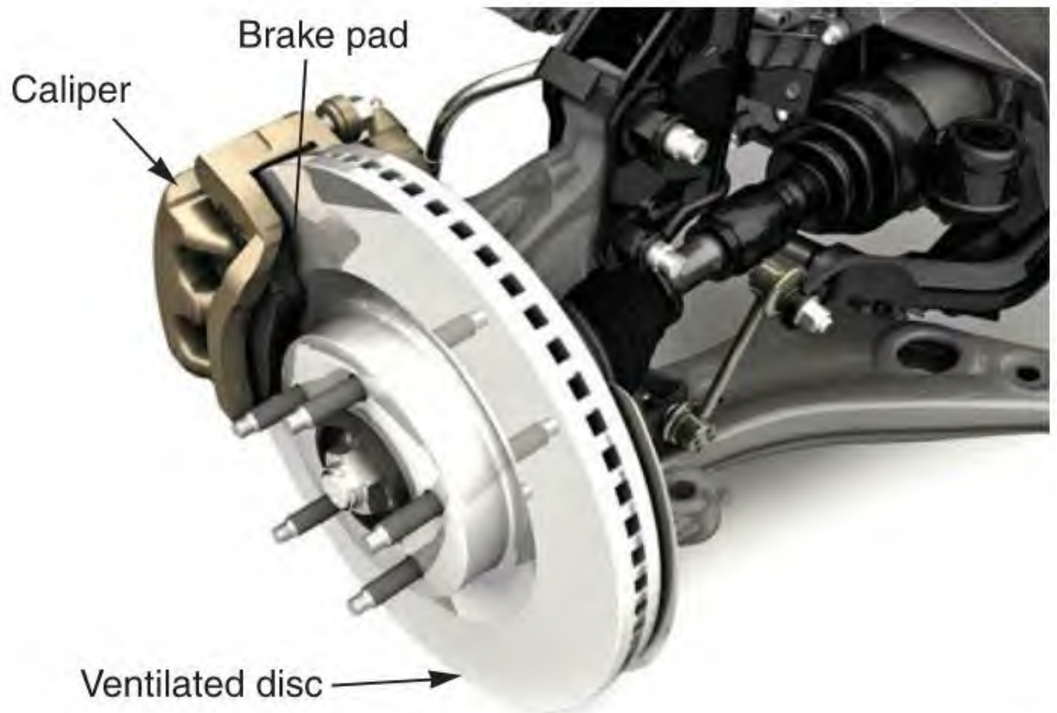
Disc Brake Assemblies



Disc brakes are basically like the brakes on a ten-speed bicycle. The friction elements are squeezed inward to clamp against a rotating disc, or wheel.

A disc brake assembly consists of a caliper, brake pads, a disc, and related hardware (bolts, clips, springs, etc.). See **Figure 80-19**. **Figure 80-20** shows section views of typical disc brake assemblies. Note how the caliper pistons move inward to clamp the brake pads against the rotor.

Brake Caliper

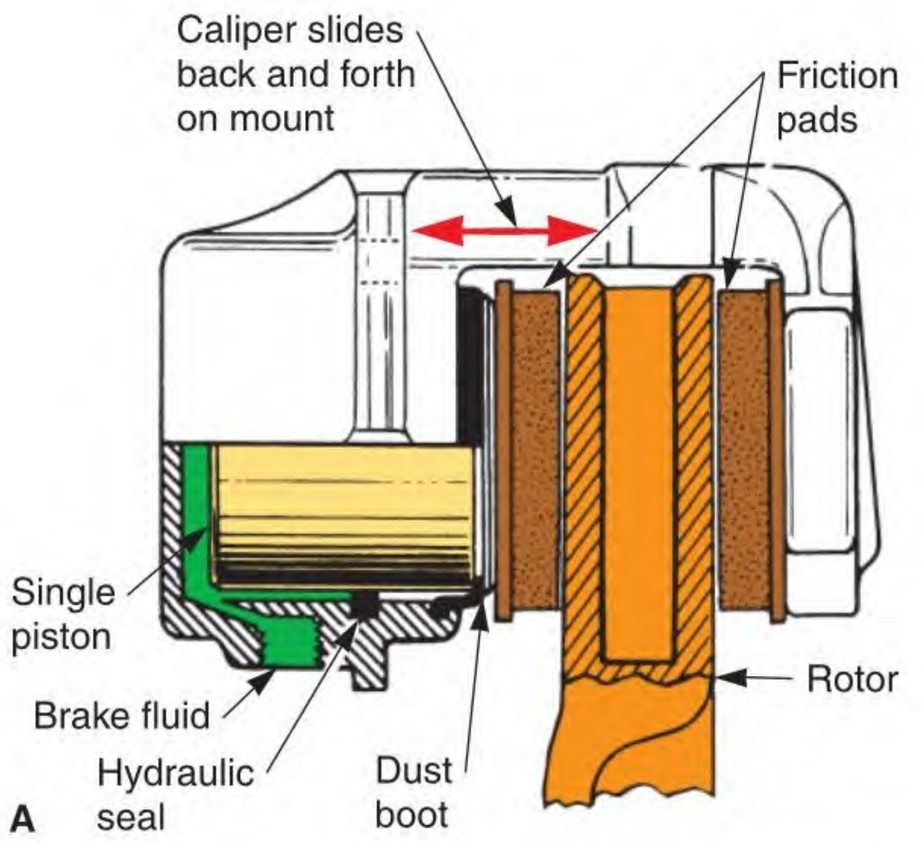


The ***brake caliper*** assembly includes the caliper housing, piston, piston seal, dust boot, brake pads, special hardware (clips, springs), and a bleeder screw. These parts are pictured in **Figure 80-21**.

Copyright Goodheart-Willcox Co., Inc.

EIS

Figure 80-18. Study how each master cylinder piston operates different wheel brake assemblies.



Ford

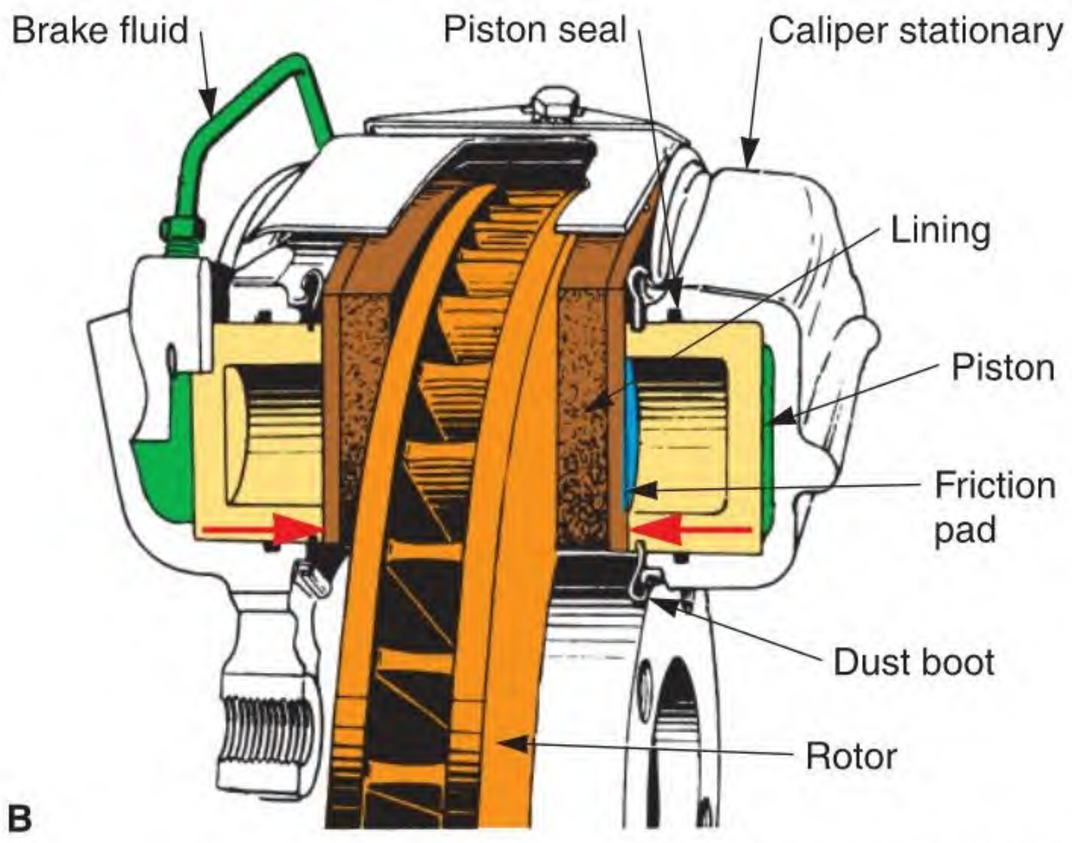


Figure 80-19. Note the parts of a disc brake unit.

When the brake pedal is applied, brake fluid flows into the caliper cylinder. The piston is then pushed outward by fluid pressure, forcing the brake pads into the disc. See **Figure 80-22**.

The ***piston seal*** in the caliper prevents pressure leakage between the piston and the cylinder. The piston seal also helps pull the piston back into the cylinder when the brakes are not applied. The elastic action of the seal acts as a spring to retract the piston.

The ***piston boot*** keeps road dirt and water off the caliper piston and the wall of the cylinder. The boot and seal usually fit into grooves cut in the caliper cylinder and piston, **Figure 80-22**.

Goodheart-Willcox Publisher

Figure 80-20. The caliper piston pushes the brake pad into a revolving disc to slow or stop the vehicle. A—The single-piston caliper is very common. The caliper floats, or slides, on its mount so both pads contact the disc. B—A fixed caliper uses pistons on both sides of disc. The caliper remains stationary on its mounting.

Copyright Goodheart-Willcox Co., Inc.

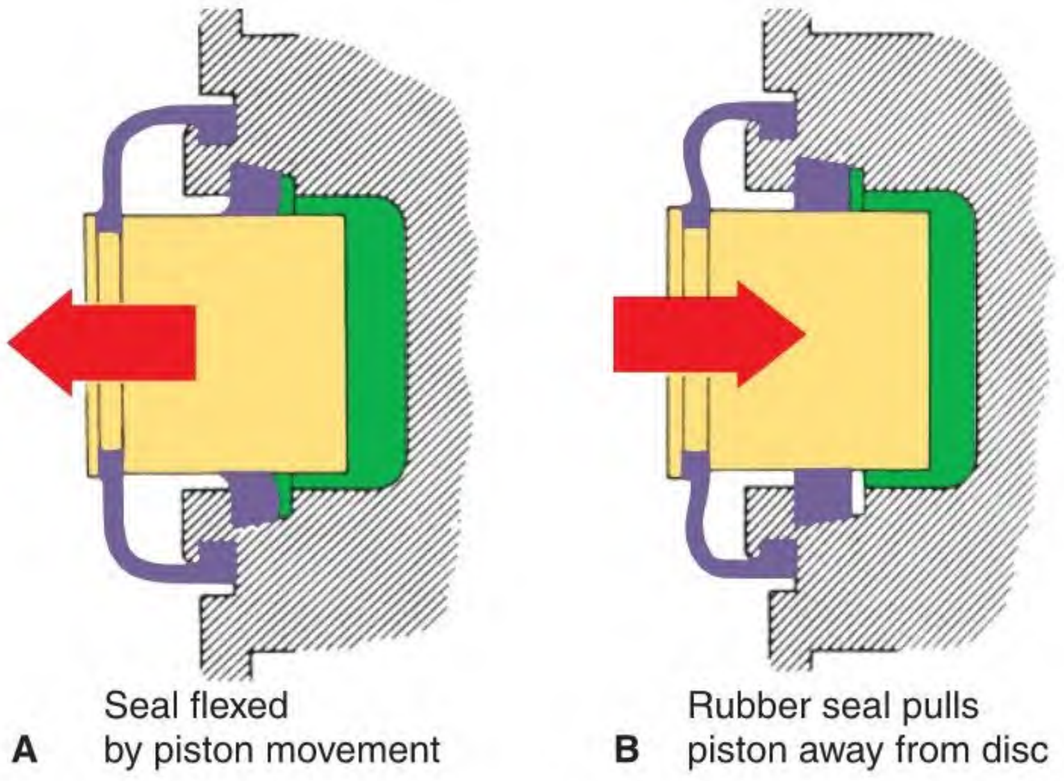
A ***bleeder screw*** allows air to be removed from the hydraulic brake system. It is threaded into the side or top of the caliper housing. When the screw is loosened, hydraulic pressure can be used to force fluid and air out of the system, **Figure 80-21**.

Disc Brake Pads

Disc brake pads are steel plates to which linings are riveted or bonded. Each caliper has an inner and outer brake pad that fits inside the hydraulic brake caliper. Refer to **Figure 80-21**.

Brake pad linings are normally made of heat-resistant organic or semimetallic (metal-particle filled) friction material. Older pad linings were made of asbestos, which has been phased out because of its cancer-causing properties. Many new vehicles, especially those with front-wheel drive, use semimetallic linings on the front. Semimetallic linings can withstand higher operating temperatures without losing their frictional properties.

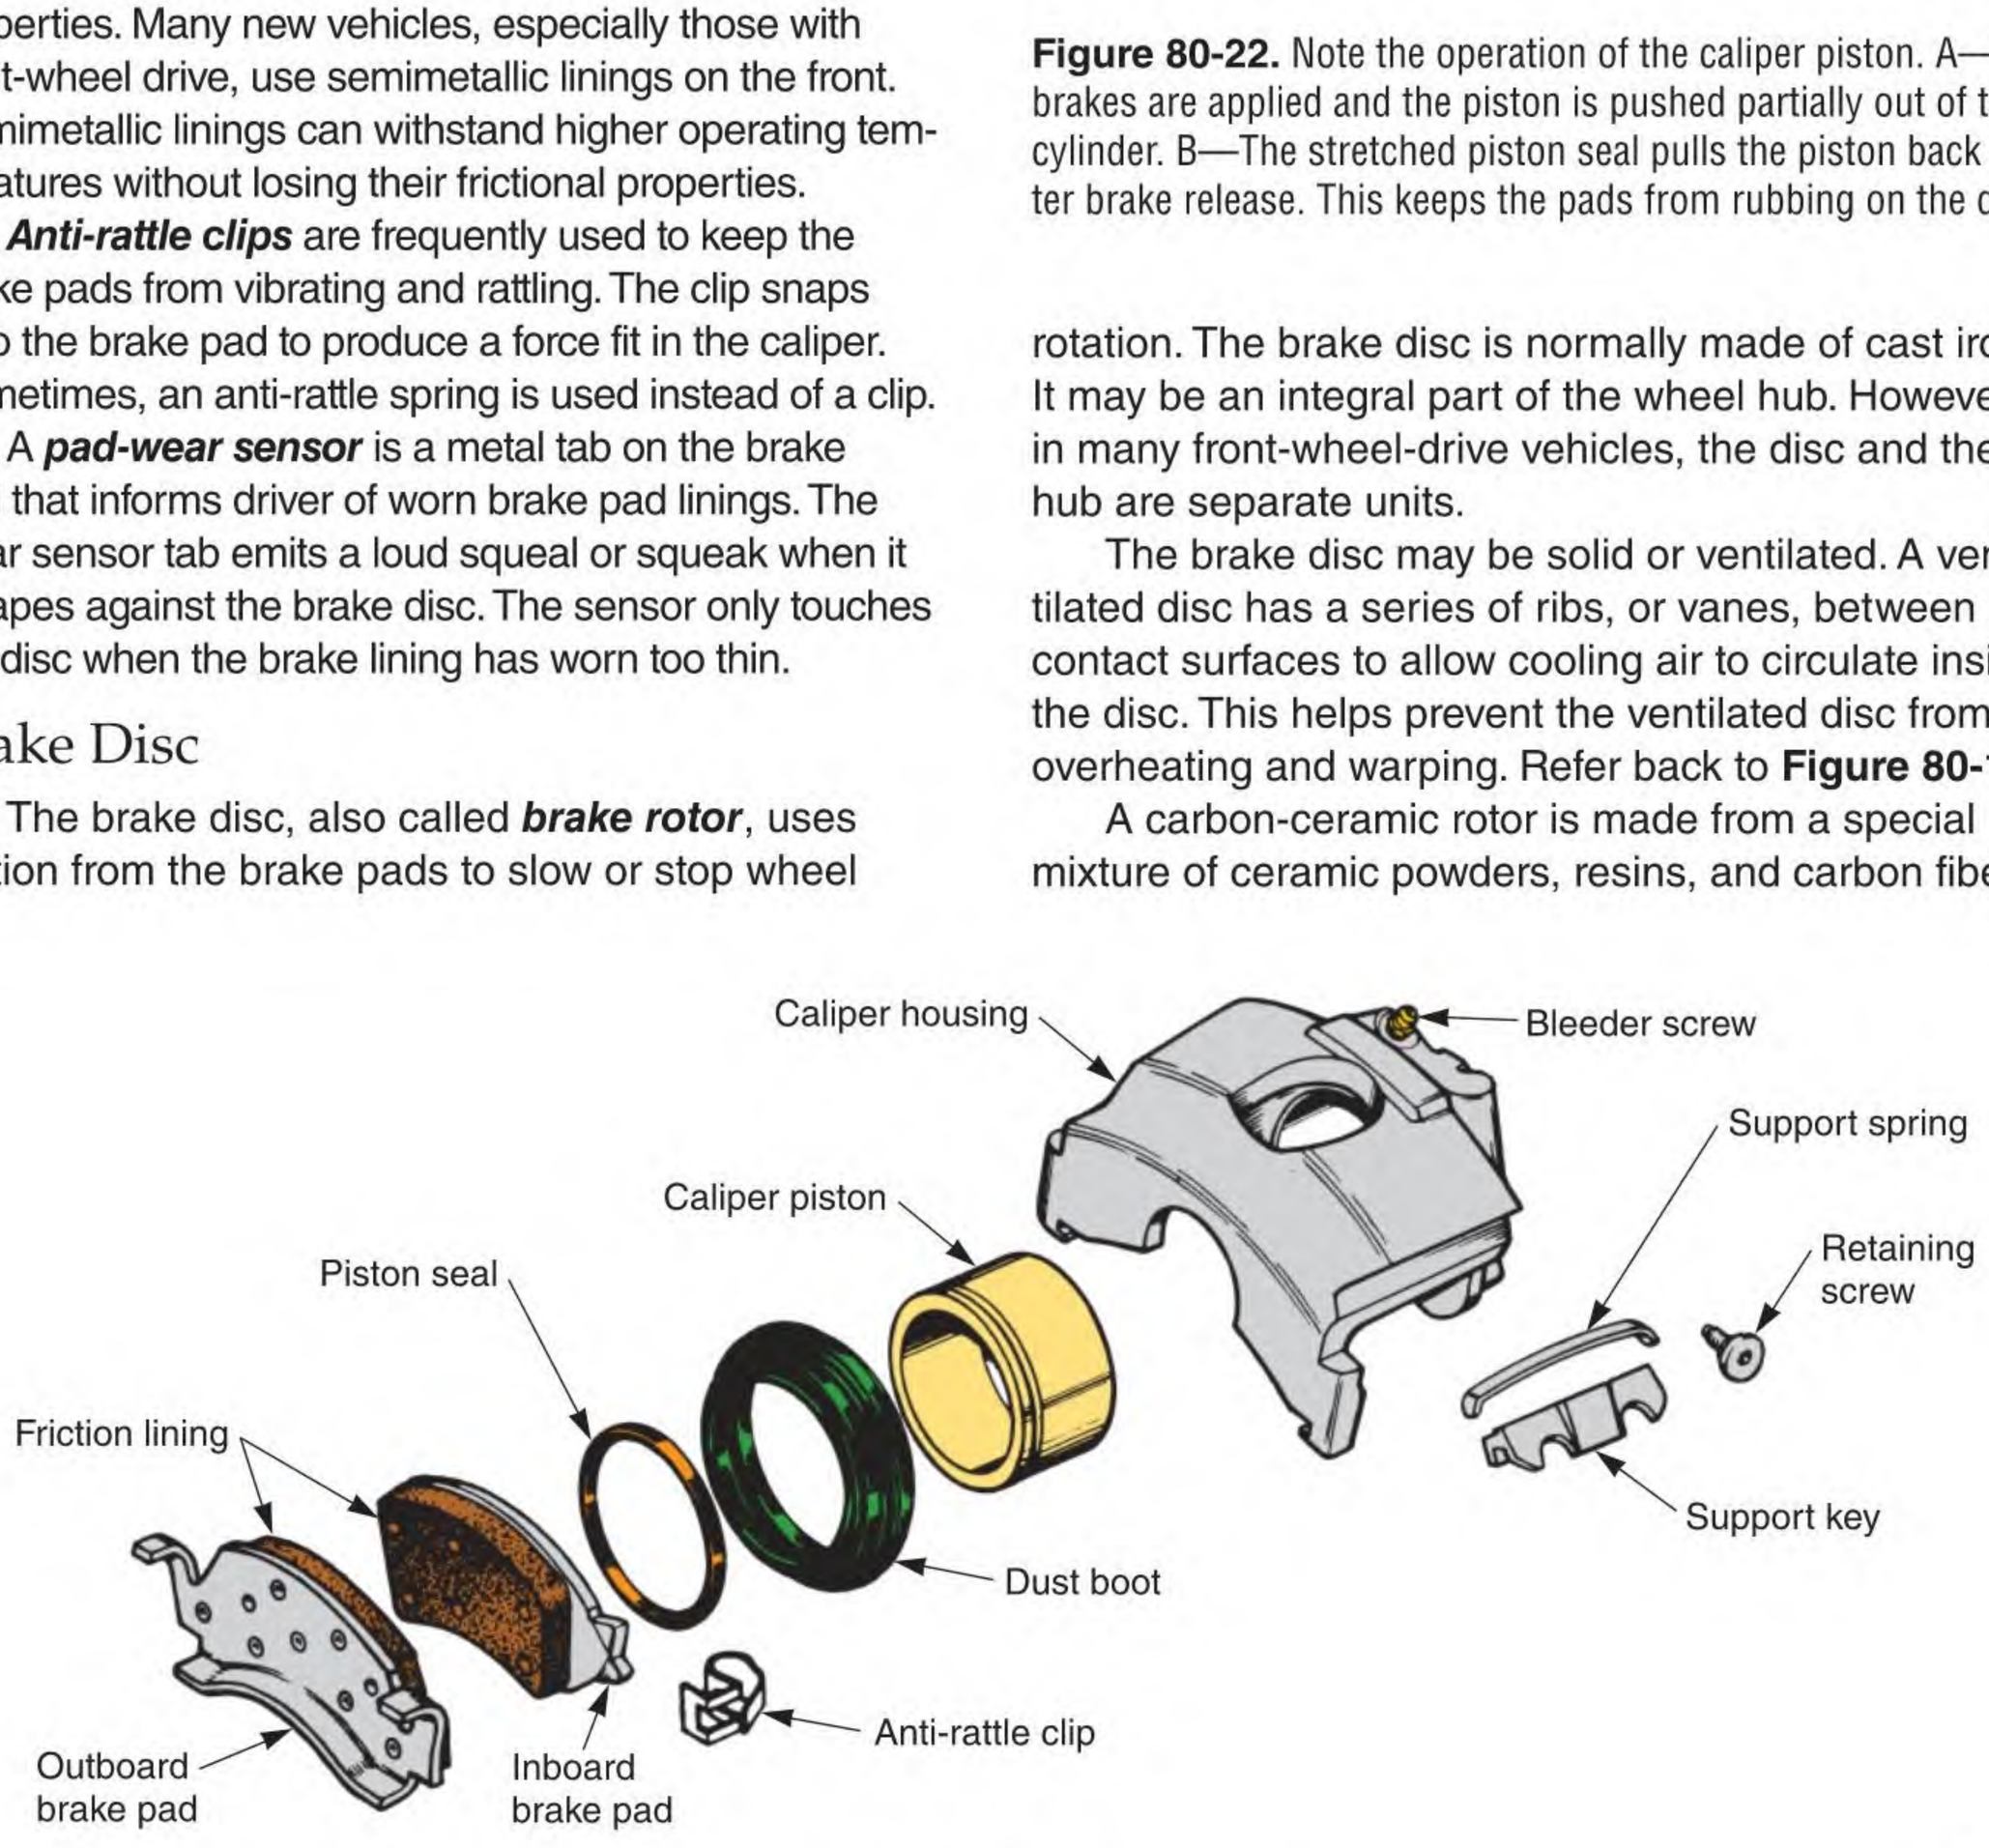
Anti-rattle clips are frequently used to keep the brake pads from vibrating and rattling. The clip snaps onto the brake pad to produce a force fit in the caliper. Sometimes, an anti-rattle spring is used instead of a clip.



A ***pad-wear sensor*** is a metal tab on the brake pad that informs driver of worn brake pad linings. The wear sensor tab emits a loud squeal or squeak when it scrapes against the brake disc. The sensor only touches the disc when the brake lining has worn too thin.

Brake Disc

The brake disc, also called ***brake rotor***, uses friction from the brake pads to slow or stop wheel rotation. The brake disc is normally made of cast iron. It may be an integral part of the wheel hub. However, in many front-wheel-drive vehicles, the disc and the hub are separate units.



The brake disc may be solid or ventilated. A ventilated disc has a series of ribs, or vanes, between its contact surfaces to allow cooling air to circulate inside the disc. This helps prevent the ventilated disc from overheating and warping. Refer back to **Figure 80-19**.

A carbon-ceramic rotor is made from a special mixture of ceramic powders, resins, and carbon fibers.

EIS

Figure 80-22. Note the operation of the caliper piston. A—The brakes are applied and the piston is pushed partially out of the cylinder. B—The stretched piston seal pulls the piston back after brake release. This keeps the pads from rubbing on the disc.

Chrysler

Figure 80-21. Study disassembled view of a caliper. Note how the parts fit together.

Copyright Goodheart-Willcox Co., Inc.

This type of rotor is much lighter than a cast iron rotor and is usually bolted to an aluminum hub. The carbon-ceramic rotor can resist and dissipate heat better than a cast iron rotor for decreased high-speed stopping distances. See **Figure 80-23**.

Disc Brake Types

Disc brakes can be classified as floating caliper brakes, sliding caliper brakes, and fixed caliper brakes. Floating and sliding calipers are common. Fixed calipers were used on a few older passenger cars.

The ***floating caliper*** disc brake is mounted on two bolts supported by rubber bushings. This one-piston caliper is free to shift, or float, in the rubber bushings.

The ***sliding caliper*** disc brake is a one-piston caliper that is mounted in slots machined in the caliper adapter. The caliper is free to slide sideways in the slots or grooves as the linings wear.

The ***fixed caliper*** disc brake normally uses more than one piston and caliper cylinder. The caliper is bolted directly to the steering knuckle. It is not free to move in relation to the disc. Pistons on both sides of the disc push against the brake pads.

Floating and sliding calipers are used to avoid vibration problems. With a fixed caliper, severe vibrations can occur with a slight ***runout*** (wobble) of the disc.

Brembo

Figure 80-23. Carbon-ceramic rotors are found on some high-performance sports cars.

Drum Brake Assemblies

Drum brakes use many of the principles covered in the section on disc brakes. However, drum brakes have a large drum that surrounds the brake shoes and the hydraulic wheel cylinder.

A drum brake assembly consists of a backing plate, a wheel cylinder, brake shoes and linings, retracting springs, hold-down springs, a brake drum, and an automatic adjusting mechanism, **Figure 80-24**. Drum brakes are becoming less common, but are still used for rear brakes on some vehicles.

Backing Plate

The ***brake backing plate*** holds the shoes, springs, wheel cylinder, and other parts inside the brake drum. It also helps keep road dirt and water off the brakes. The backing plate bolts to the axle housing or the spindle support.

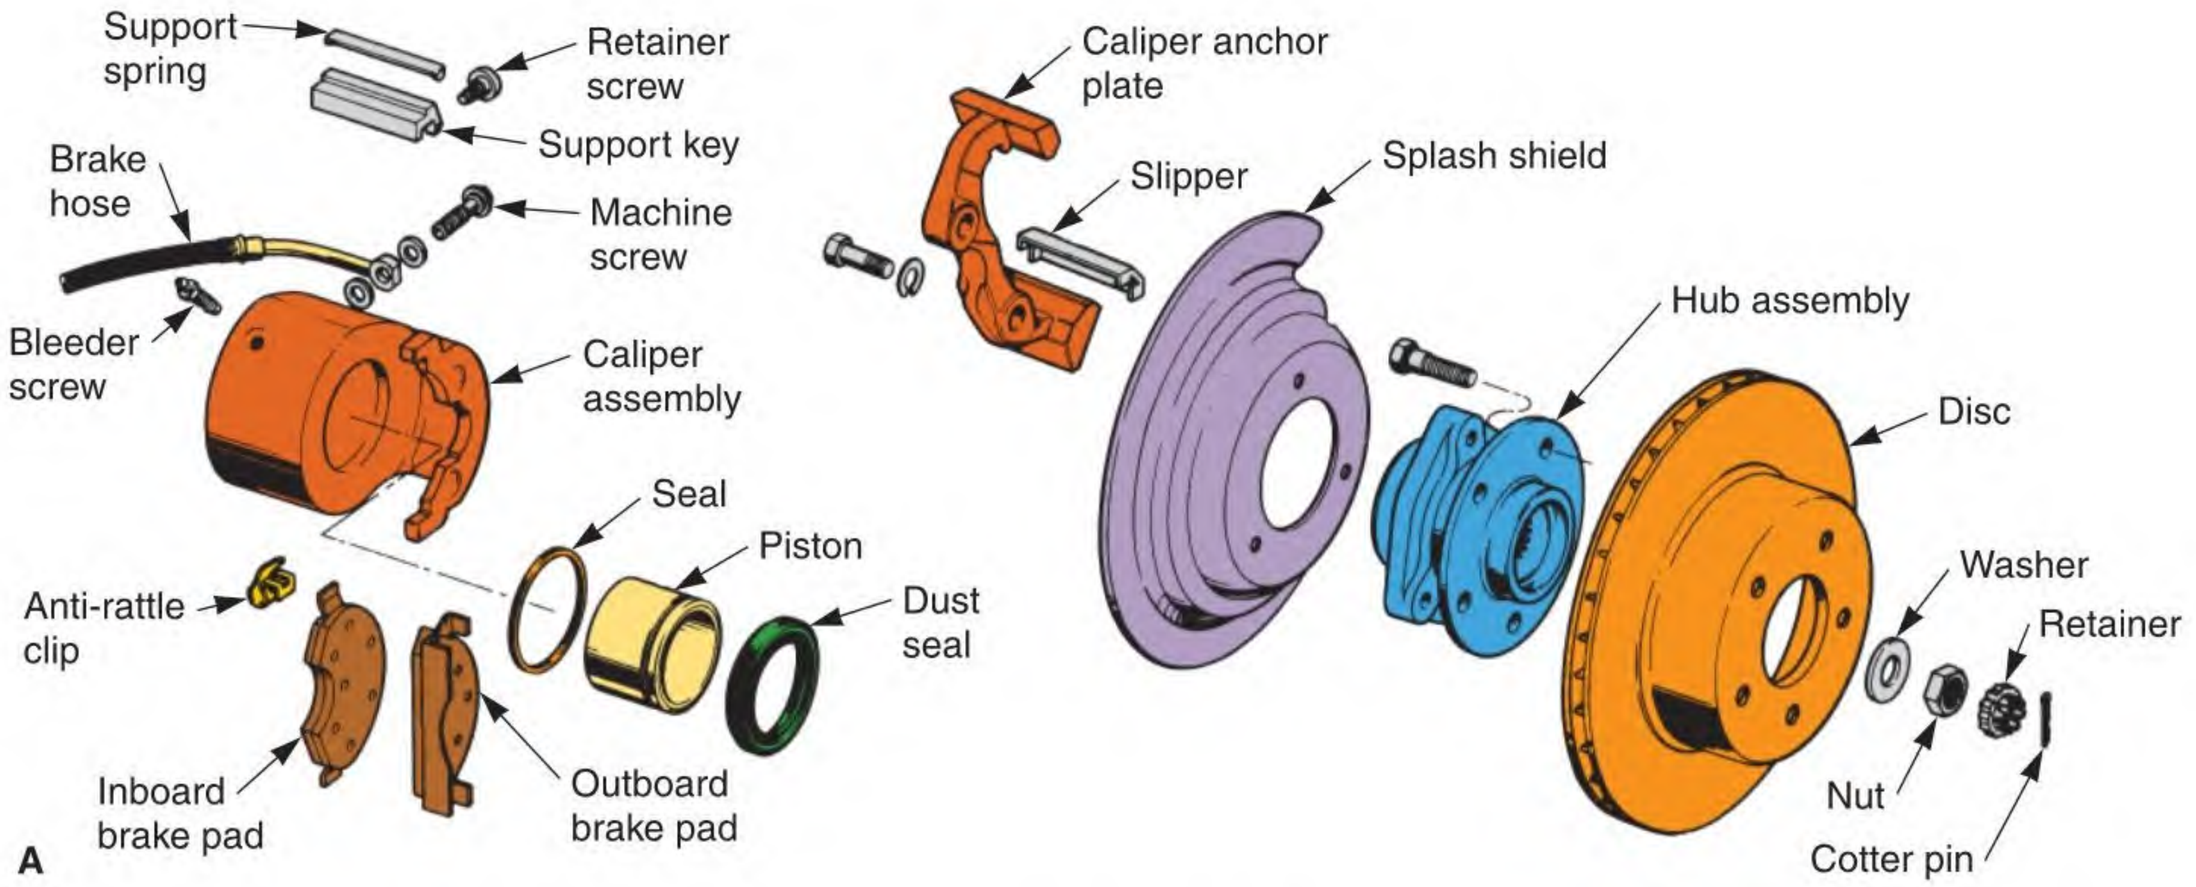
Wheel Cylinder Assembly

The wheel cylinder assemblies use master cylinder pressure to force the brake shoes out against the brake drums. The cylinders bolt to the top of the backing plates.

A ***wheel cylinder*** consists of a cylinder or housing, an expander spring, rubber cups, pistons, dust boots, and a bleeder screw. See **Figure 80-25**.

The ***wheel cylinder housing*** forms the enclosure for the other parts of the assembly. It has a precision honed cylinder in it for the pistons, the cups, and the spring.

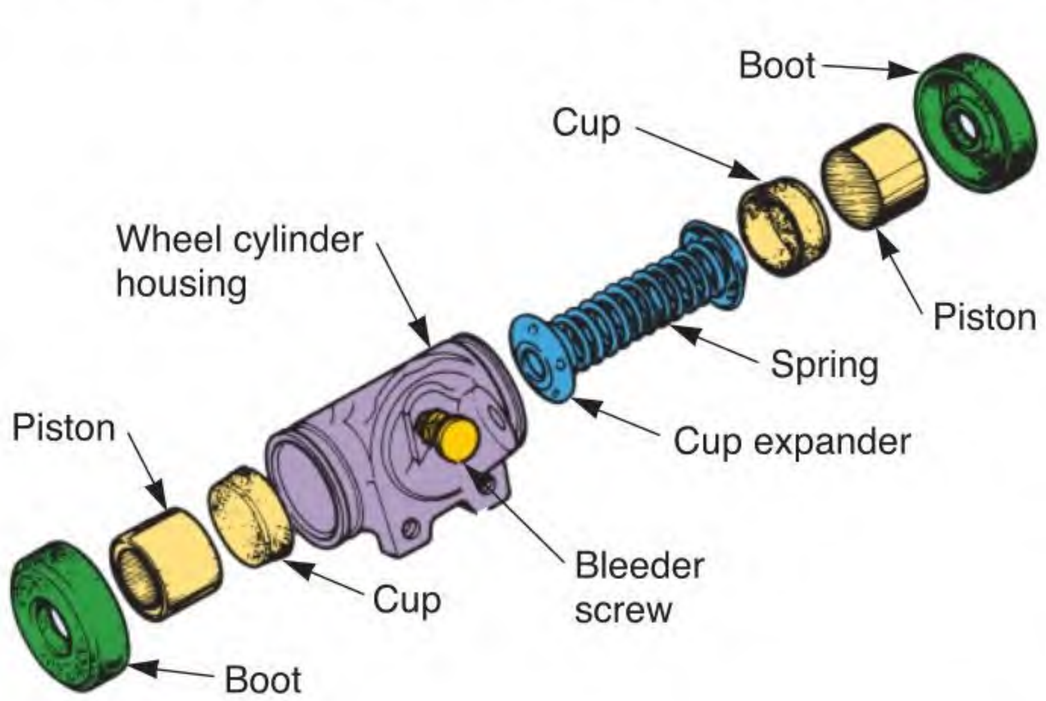
The ***wheel cylinder boots*** keep road dirt and water out of the cylinder. They snap into grooves on the outside of the housing.



The ***wheel cylinder pistons*** are metal or plastic plungers that transfer force out of the wheel cylinder assembly. They act on push rods connected to the brake shoes or directly on the shoes.

The ***wheel cylinder cups*** are rubber seals that keep fluid from leaking past the pistons. They fit in the cylinder and against the pistons.

The ***wheel cylinder spring*** helps hold the rubber cups against the pistons when the wheel cylinder assembly is not pressurized. Sometimes, the ends of this spring have metal expanders. Called ***cup expanders***, they help press the outer edges of the cups against the wall of the wheel cylinder.



The bleeder screw provides a means of removing air from the brake system. It threads into a hole in the back of the wheel cylinder. When the screw is loosened, hydraulic pressure can be used to force air and fluid out of the system. Refer to **Figure 80-26**.

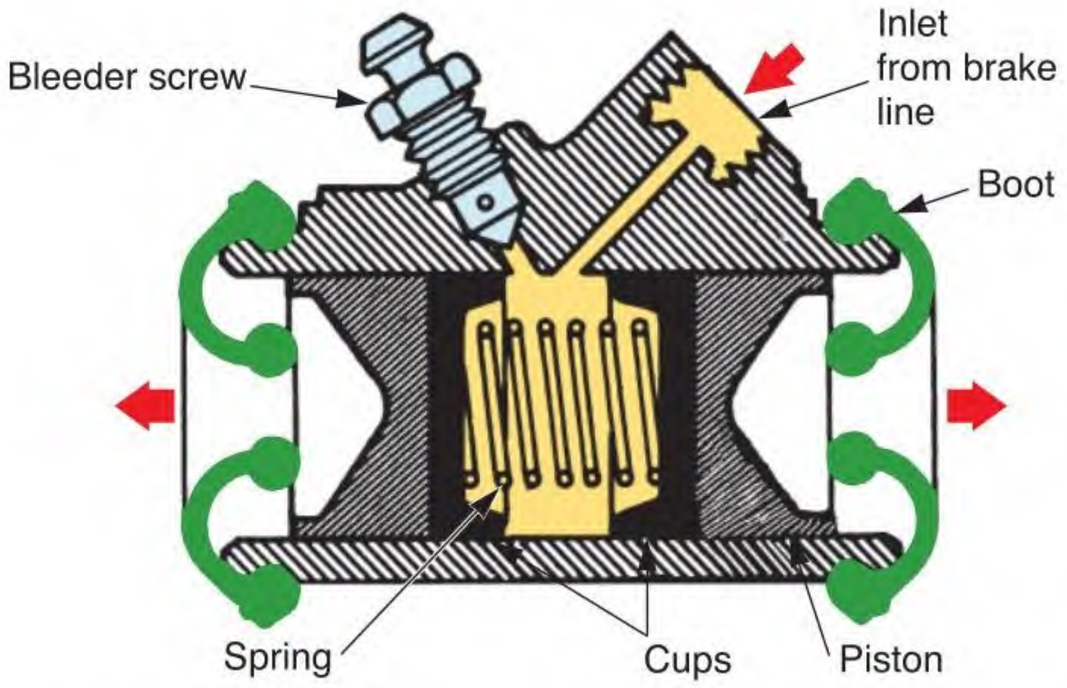
Renault

Figure 80-25. This exploded view shows a wheel cylinder for a drum brake. The cups prevent fluid leakage out of the cylinder. The boots keep debris out of the cylinder.

Drum Brake Shoes



The ***drum brake shoe assemblies***, or brake shoes, rub against the revolving brake drum to produce braking action. Drum brake shoe assemblies are made by fastening friction material onto a metal shoe. The lining is a heat-resistant surface that contacts the brake drum.

The metal shoe supports and holds the soft lining material. The lining may be held on the shoe by either rivets or a bonding agent (glue).

The ***primary brake shoe*** is the front shoe. It normally has a slightly shorter lining than the secondary shoe.

The ***secondary brake shoe*** is the rear shoe. It has the largest lining surface area.

Copyright Goodheart-Willcox Co., Inc.

EIS

Figure 80-26. This cutaway view of a drum brake wheel cylinder shows the fluid passages to the cylinder and the bleeder screw. Pressure inside the cylinder pushes the cups and pistons outward to force the linings into the drum.

Retracting Springs and Hold-Down Springs

Retracting springs pull the brake shoes away from the brake drums when the brake pedal is released. This, in turn, pushes the wheel cylinder pistons inward. Usually, the retracting springs fit in holes in the shoes and around an anchor pin at the top of the backing plate.

Hold-down springs hold the brake shoes against the backing plate when the brakes are in the released position. A hold-down pin fits through the back of the backing plate. Metal cups lock onto these pins to secure the hold-down springs to the shoes. Some manufacturers use spring clips instead of hold-down springs and locking cups. Others use a spring that is simply hooked to the shoe and the backing plate.

All brake springs are made from high-quality steel that is capable of withstanding the high temperatures encountered inside the brake drum.

Brake Shoe Adjusters

Brake shoe adjusters maintain the correct drum-to-lining clearance as the brake linings wear.

Many vehicles use a star wheel–type (screw-type) brake shoe adjusting mechanism. This type of adjusting mechanism includes a ***star wheel*** (adjusting screw assembly), an adjuster lever, an adjuster spring, and either an adjuster cable, lever arm, or link (rods). Other vehicles use latch-type adjusters. See **Figure 80-27**.

Automatic brake shoe adjusters normally function when the brakes are applied with the vehicle moving in reverse. If there is too much lining clearance, the brake shoes move outward and rotate with the drum enough to operate the adjusting lever. This lengthens the star wheel assembly. The linings are moved closer to the brake drum, maintaining the correct lining-to-drum clearance.

Brake Drums

Brake drums provide a rubbing surface for the brake shoe linings. The drum usually fits over the wheel lug studs. A large hole in the middle of the drum centers the drum on the front hub or the rear axle flange. The wheel and drum turn as a unit. See **Figure 80-28**.

Brake Shoe Energization

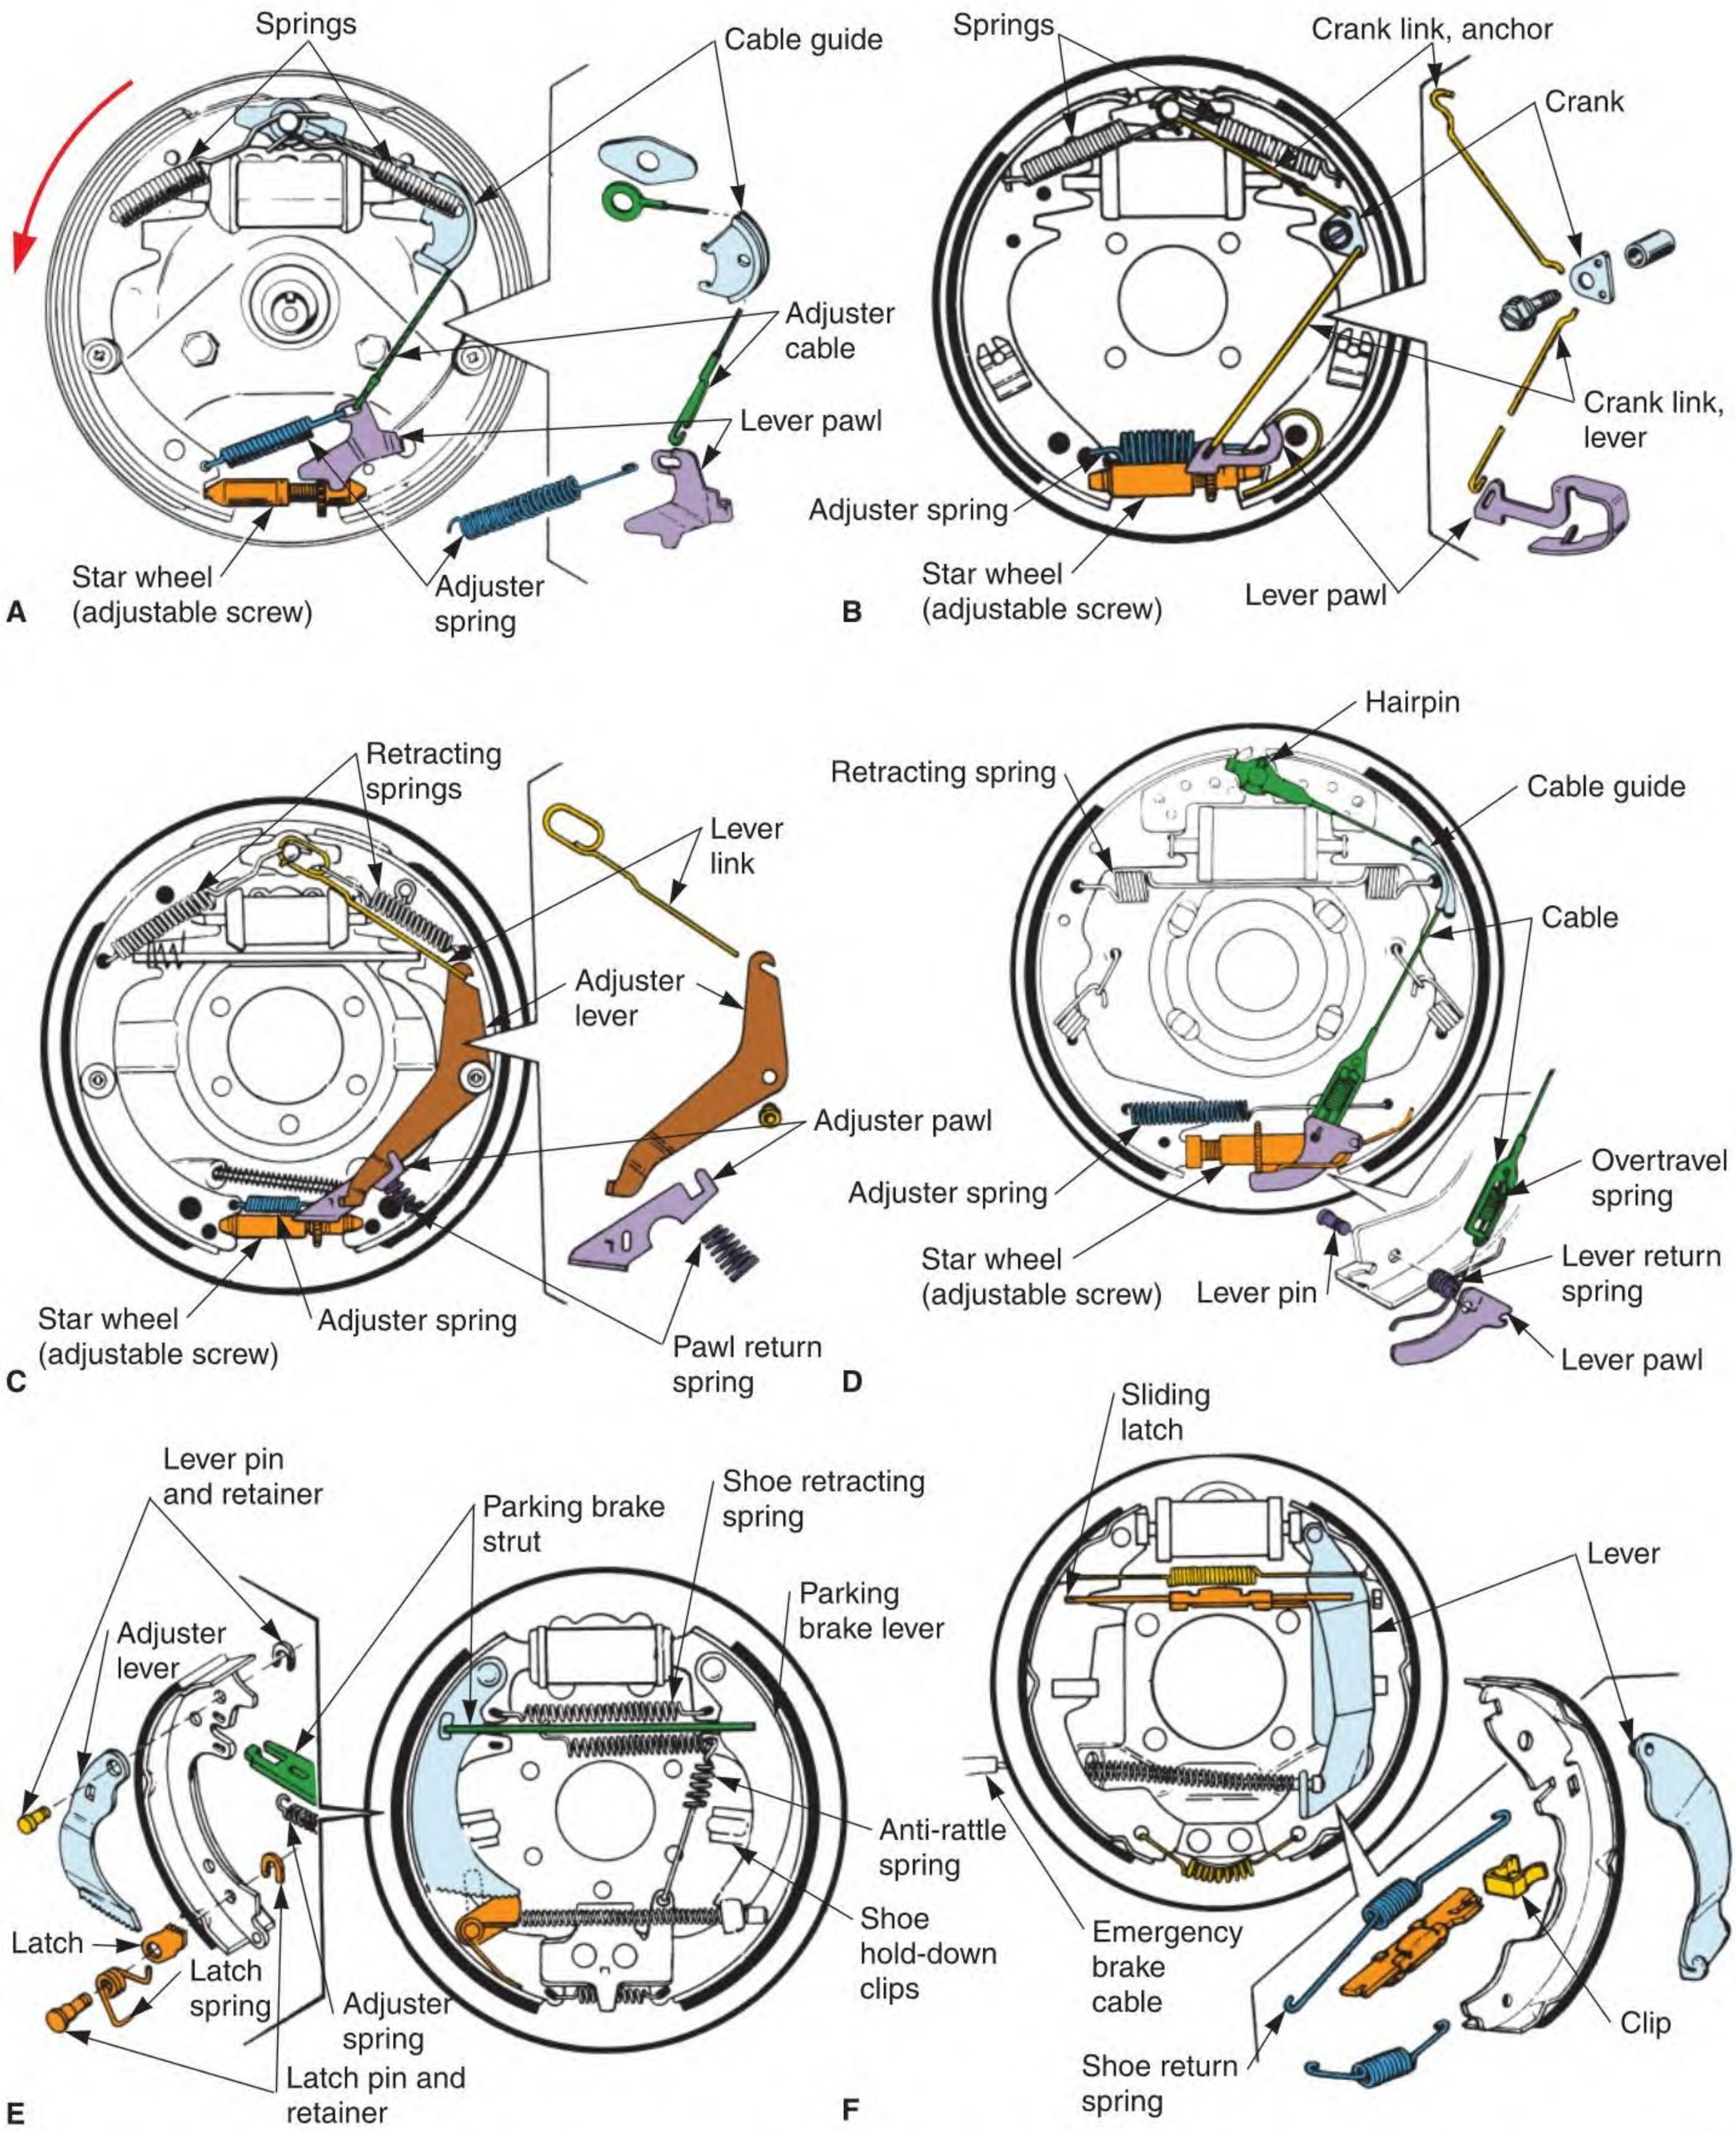
When the brake shoes are forced against the rotating drum, they are pulled away from their pivot point by friction. This movement, called ***self-energizing action***, draws the shoes tighter against the drum, **Figure 80-29A**.

With most drum brake designs, shoe energization is supplemented by servo action. ***Servo action*** results when the primary (front) shoe helps apply the secondary (rear) shoe. Study **Figure 80-29B**.

The backing plate anchor pin holds the secondary shoe during brake application. However, the primary shoe is free to float out and push against the end of the secondary shoe through the star wheel assembly. This action presses the secondary shoe into the drum with extra force.

Less wheel cylinder hydraulic pressure is needed to apply the brakes because of servo action.

Brake System Switches



There are three types of switches commonly used in a brake system: the stoplight switch, brake warning light switch, and low-fluid warning light switch.

Stoplight Switch

The ***stoplight switch*** is a spring-loaded electrical switch that operates the rear brake lights of the vehicle. Most modern cars use a mechanical switch on the brake pedal mechanism. The switch is normally open. When the brake pedal is pressed, it closes the switch and turns on the brake lights.

Hydraulically operated stoplight switches are used on some older vehicles. Brake system pressure pushed on a switch diaphragm and closed the switch that operated the brake lights.

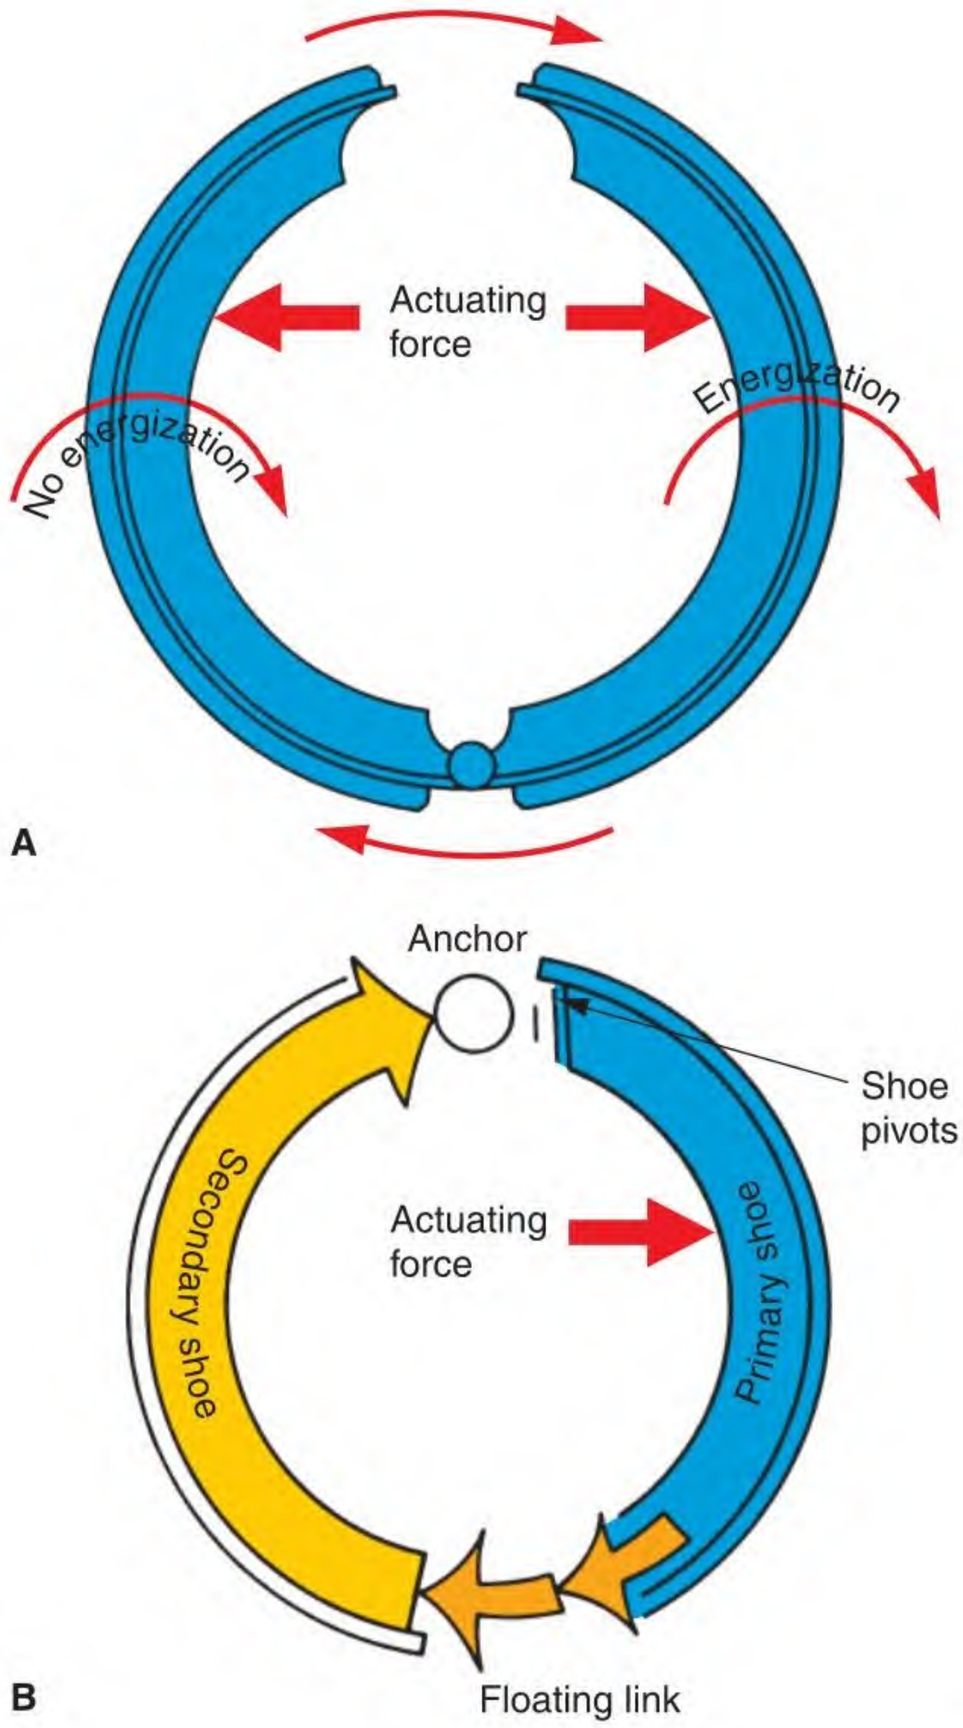
Ford

Figure 80-28. The brake drum provides a friction surface for the brake shoe linings. Study the construction of the drum.

Brake Warning Light Switch (Pressure Differential Valve)

The ***brake warning light switch***, also called the ***pressure differential valve***, warns the driver of a pressure loss on one side of a dual brake system. Look at **Figure 80-30**.

If a leak develops in either the primary or secondary brake system, unequal pressure acts on the warning light switch piston. This pushes the piston to one side, grounding the indicator circuit, **Figure 80-31**.



Low-Fluid Warning Light Switch

The ***low-fluid warning light switch*** turns on a dash light if the brake fluid in the master cylinder becomes low. It is a small switch that often mounts in the master cylinder lid or cover.

A float sometimes operates the switch. If the level of brake fluid in the reservoir drops below a critical point, the float moves down and turns the switch on. This illuminates a warning light, alerting the driver to a brake system problem. If the fluid level becomes too low, air will be pumped into the system, possibly causing a loss of braking action.

Brake System Control Valves

Many brake systems use control valves to regulate the pressure going to each wheel cylinder. The three types of valves are the metering valve, the proportioning valve, and the combination valve.

EIS

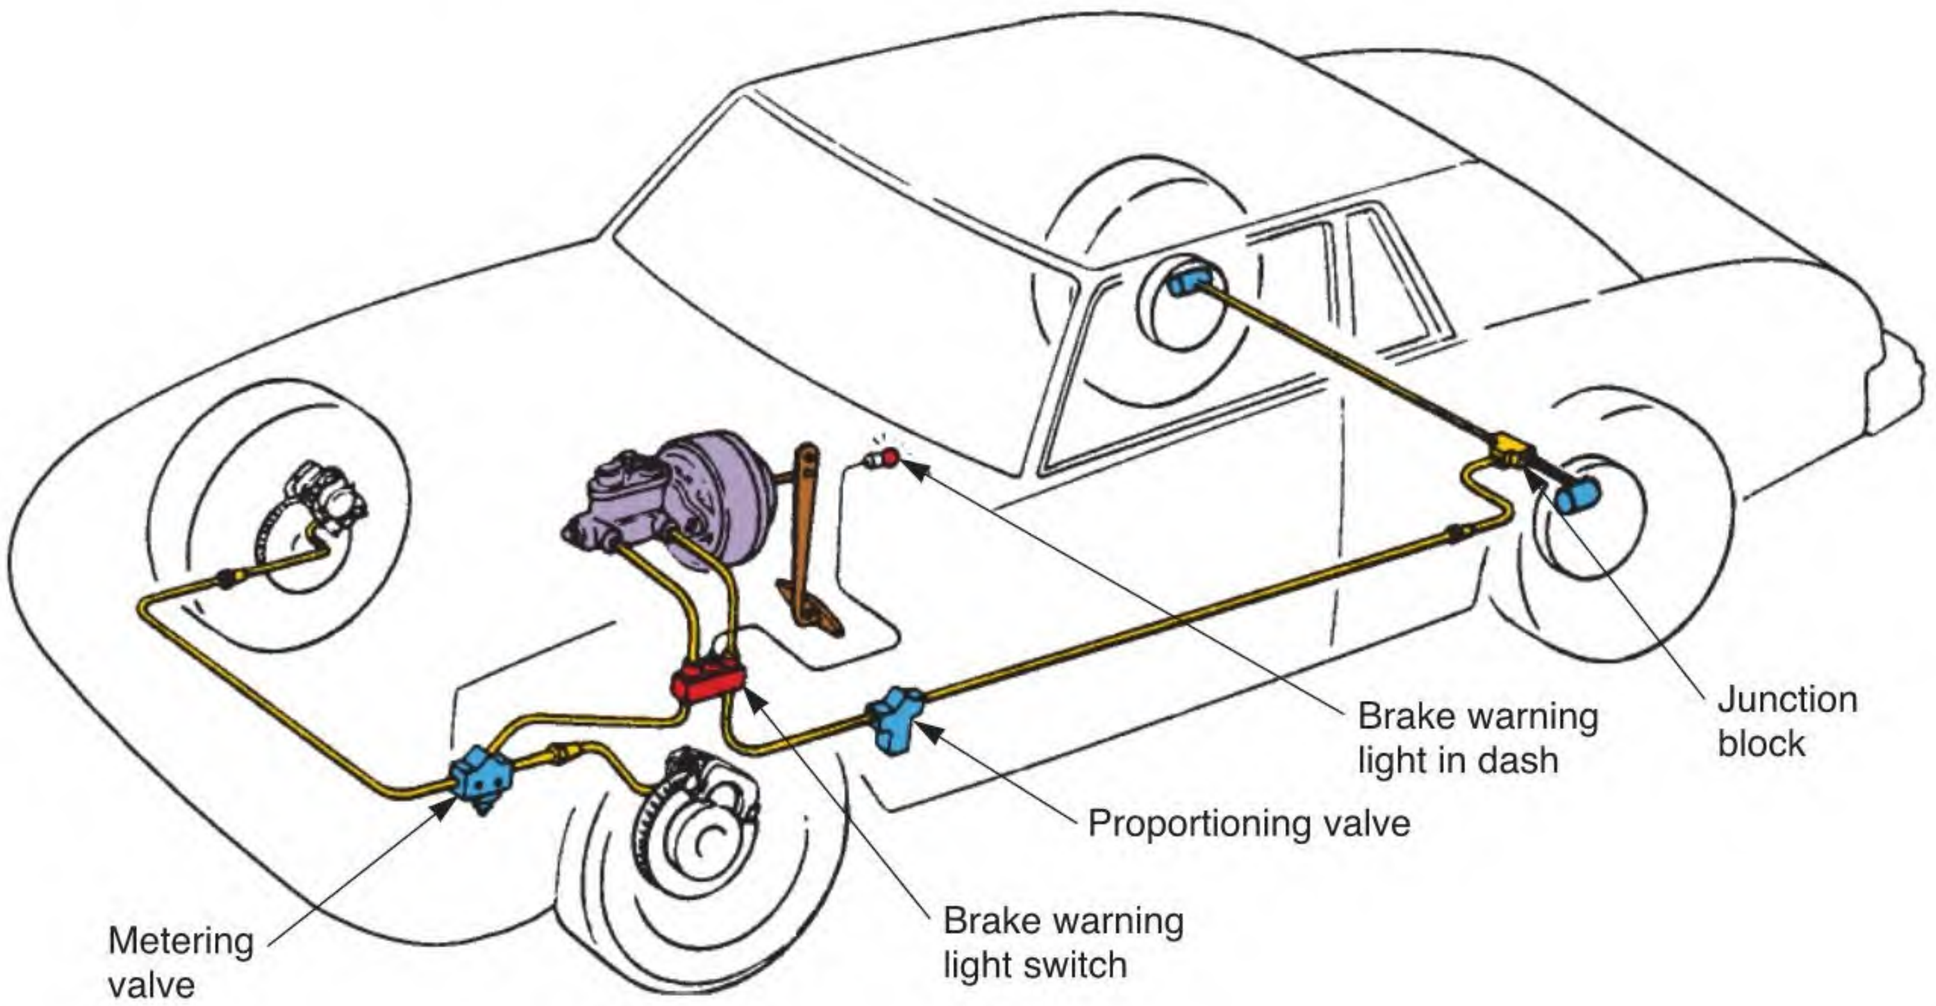


Figure 80-29. Note how brakes help apply linings to increase friction. A—Self-energizing brakes use friction to force one brake shoe tighter against drum. B—Servo action results when both shoes are free to swing into the drum and the primary shoe helps apply the secondary shoe.

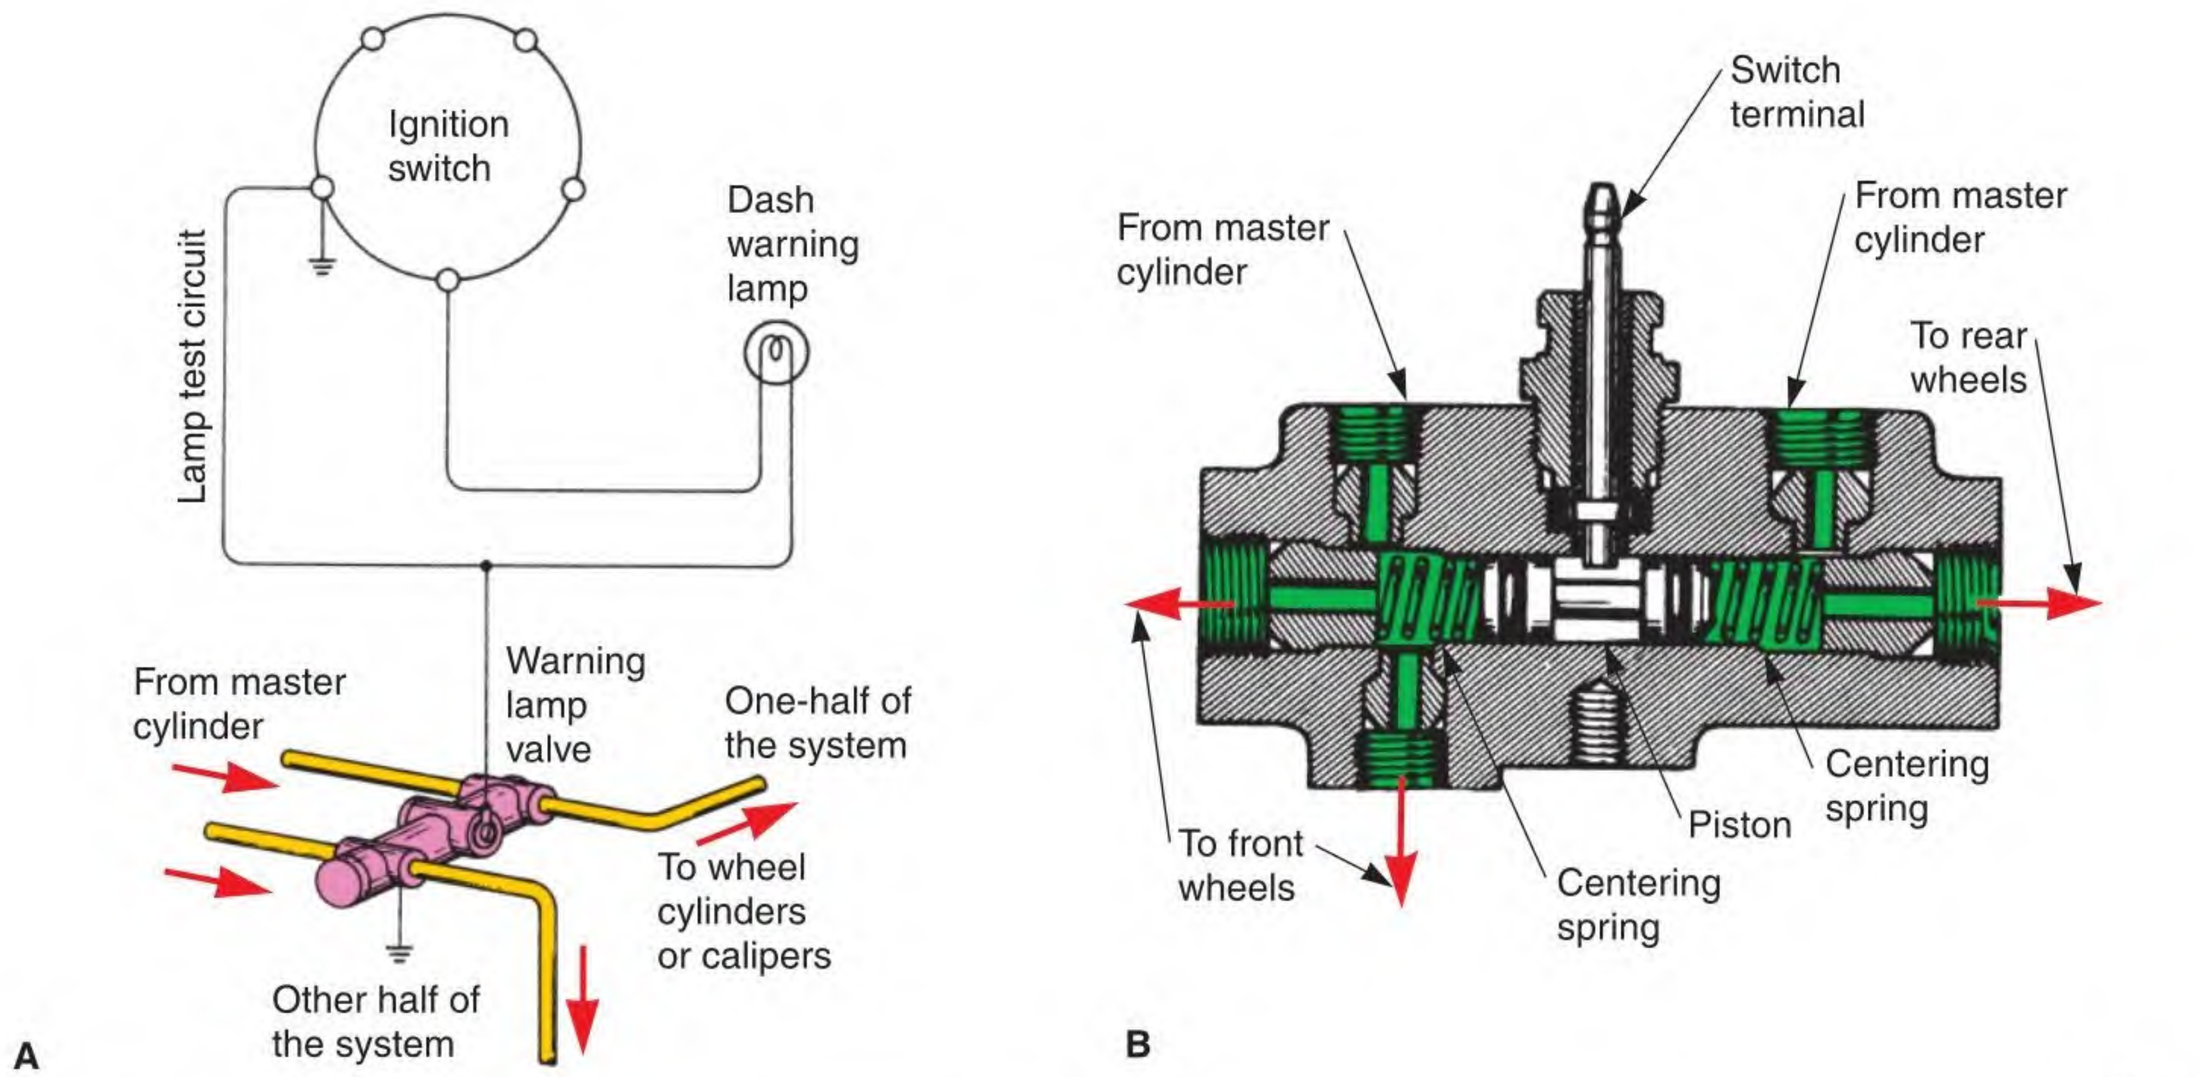
Metering Valve

A ***metering valve*** is designed to equalize braking action at each wheel during light brake applications. A metering valve is used on vehicles with front-wheel disc brakes and rear-wheel drum brakes. The metering valve is located in the line to the disc brakes, **Figure 80-30**.



The metering valve functions by preventing the front disc brakes from applying until approximately 75–135 psi (517–930 kPa) has built up in the system. This pressure overcomes the rear drum brake return springs. Since the

Copyright Goodheart-Willcox Co., Inc.

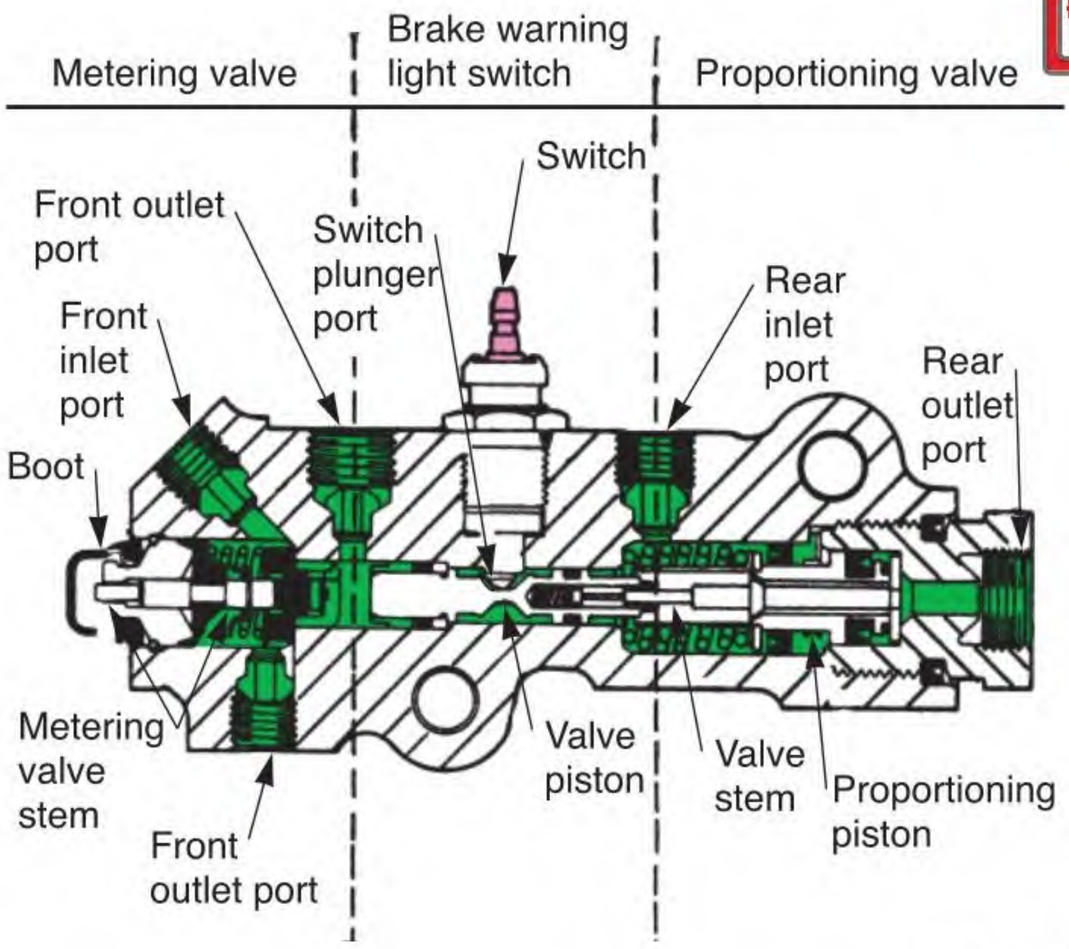
metering valve delays front brake application until this pressure is reached, the front disc brakes and the rear drum brakes will engage simultaneously.

Proportioning Valve

A ***proportioning valve*** is also used to equalize braking action in systems with front disc brakes and rear drum brakes. It is commonly located in the brake line to the rear drum brakes. Look at **Figure 80-30**.

The function of the proportioning valve is to limit pressure at the rear drum brakes when high pressure is needed to apply the front disc brakes. Thus, the proportioning valve prevents rear-wheel lockup during heavy brake applications.

Combination Valve



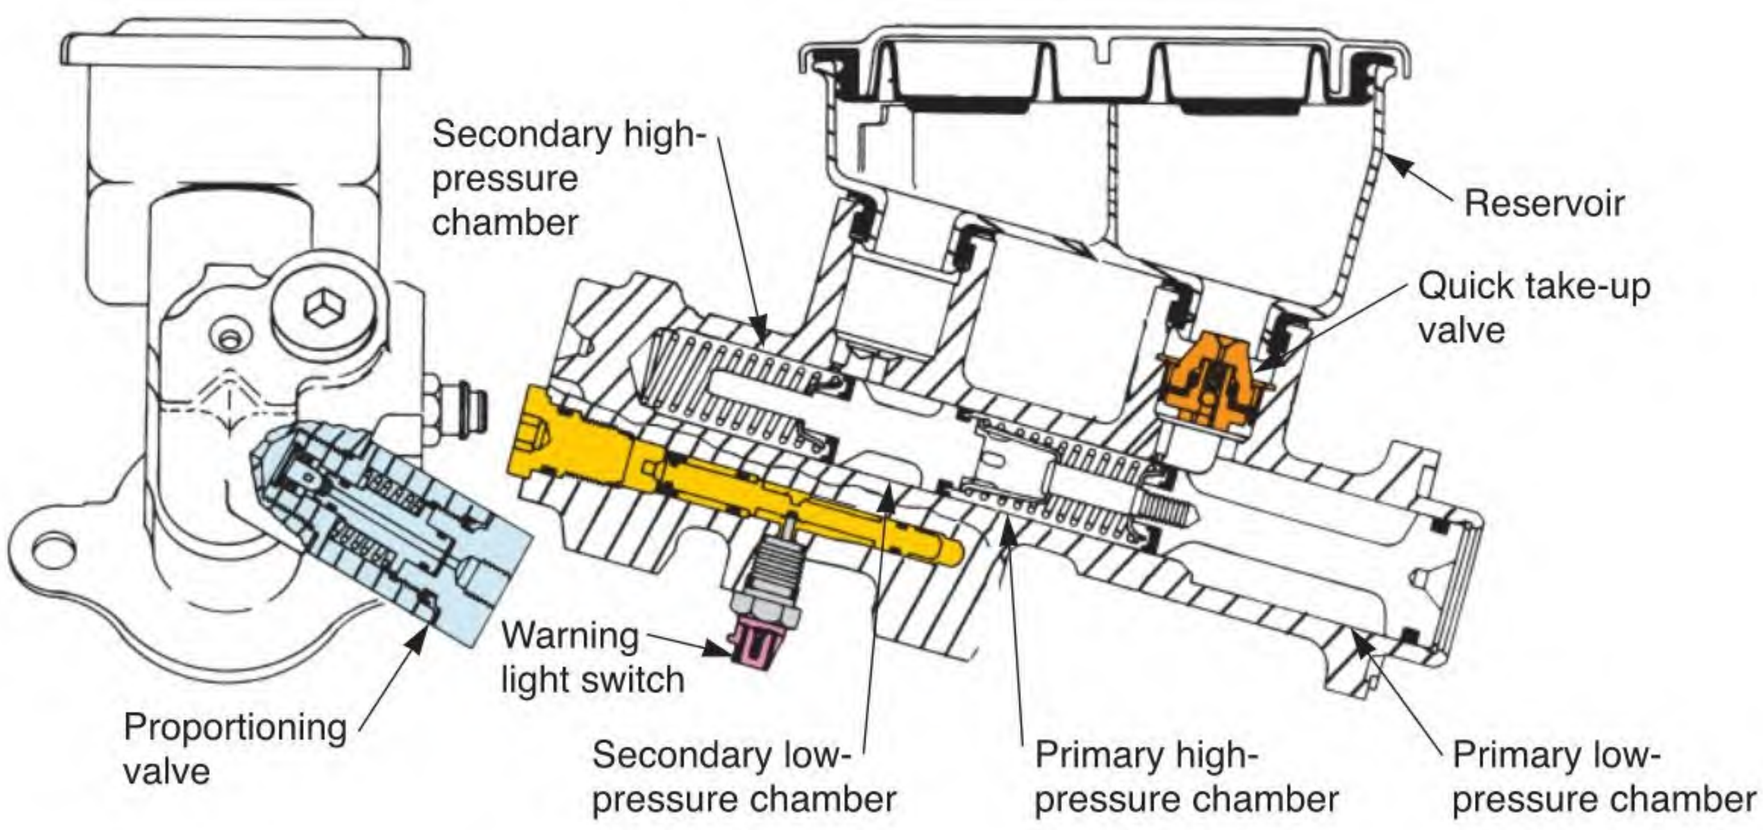
A ***combination valve*** is a single unit that functions as a brake warning light switch, a metering valve, and/or a proportioning valve. Many late-model vehicles use a combination valve. Refer to **Figure 80-32**.

With some master cylinders, the proportioning and warning lamp valves are mounted inside the master cylinder housing. This design uses the same operating principles, **Figure 80-33**.

Parking Brakes

Parking brakes, also called emergency brakes, provide a mechanical means (cable and levers) of applying the brakes. One is pictured in **Figure 80-34**.

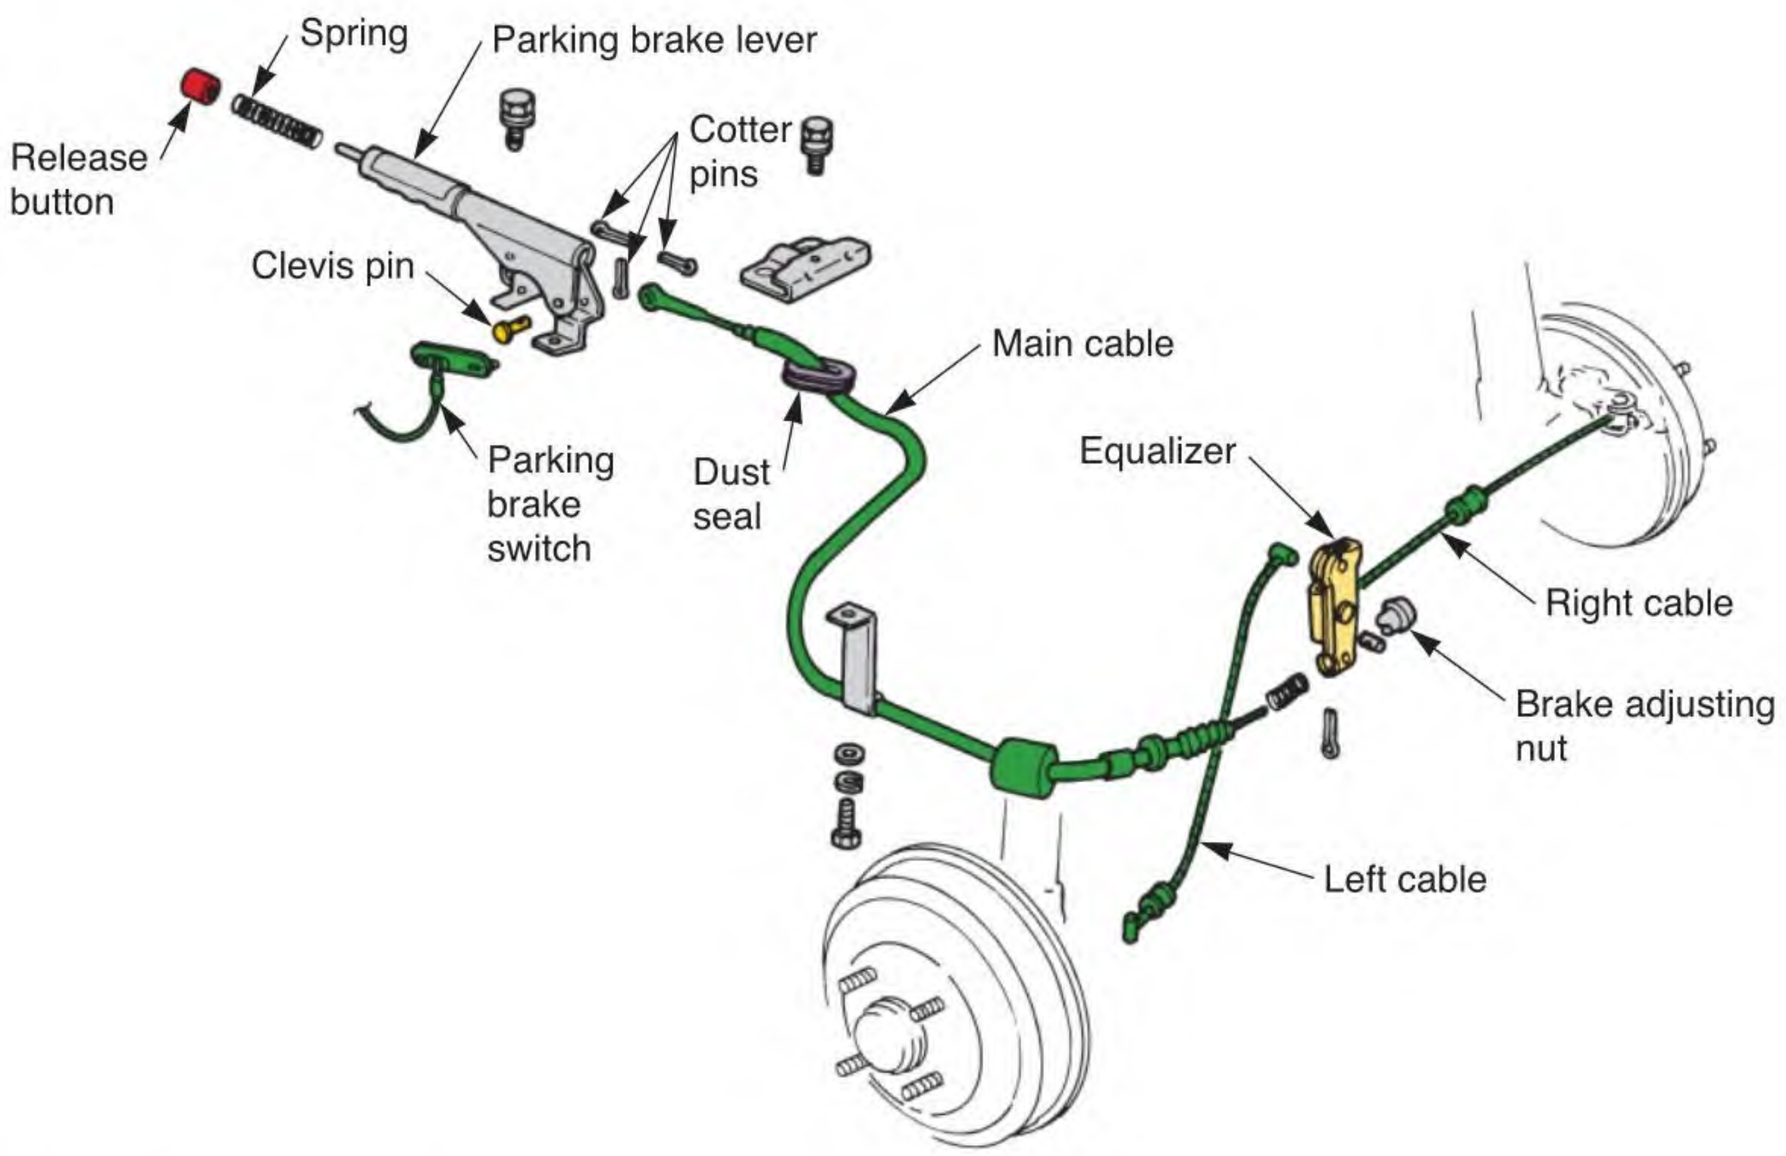
When the parking brake hand or foot lever is activated, it pulls a steel cable that runs through a



Chrysler

Figure 80-32. Study the sections of this combination valve.

housing. The movement of the cable pulls on a lever inside the drum or disc brake assembly. The lever action forces the brake linings against the rear drums or discs to resist vehicle movement. **Figure 80-35** shows a foot-operated parking brake unit.



When disc brakes are used on the rear of a vehicle, a thrust screw and a lever can be added to the brake caliper. Then, when the parking brake is applied, the cable pulls on the caliper lever. The caliper lever turns the large thrust screw, which pushes on the caliper piston and applies the brake pads to the disc. See **Figure 80-36**.

Delco

Figure 80-33. This master cylinder has a proportioning valve and a warning light switch mounted internally.

Toyota

Figure 80-34. Study the parts of this typical parking brake mechanism.

An ***electric parking brake*** uses the brake system control module to operate an electric servo motor that mechanically engages the rear brakes. A dashboard-mounted button signals the control module to apply the parking brake. A control module power transistor then operates the servo motor to apply the rear wheel brake assemblies. See **Figure 80-37**.

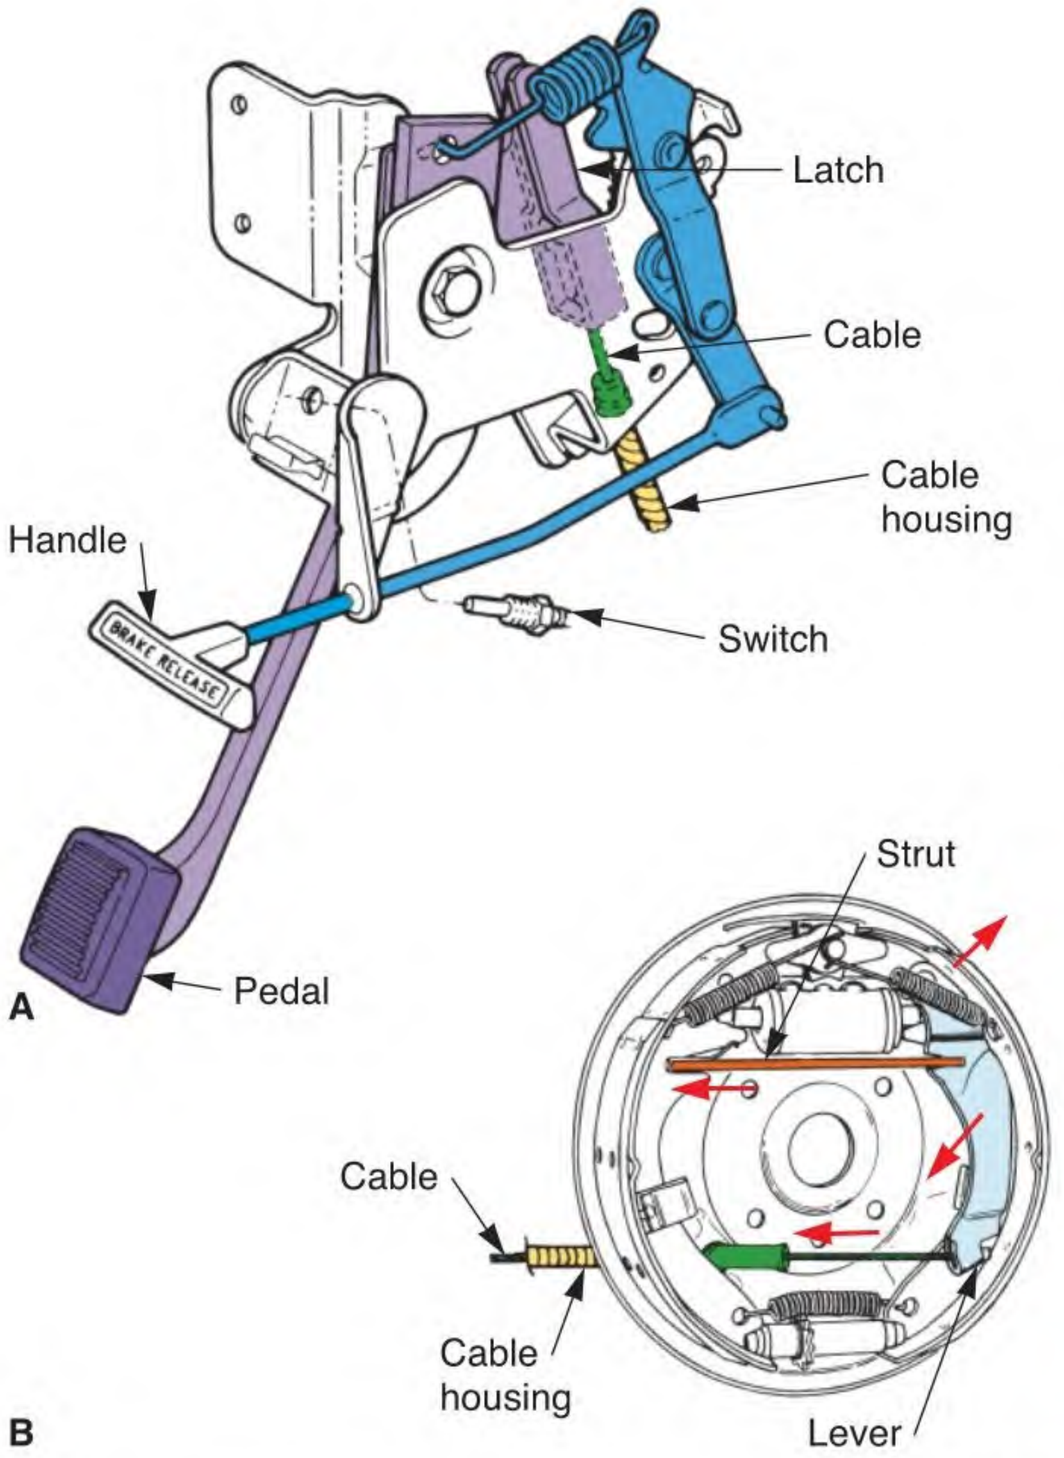
Tech Tip

Regenerative braking systems are explained in several other chapters of this textbook. Please refer to the Index for more information on hybrids and regenerative braking systems.

Hybrid Brakes

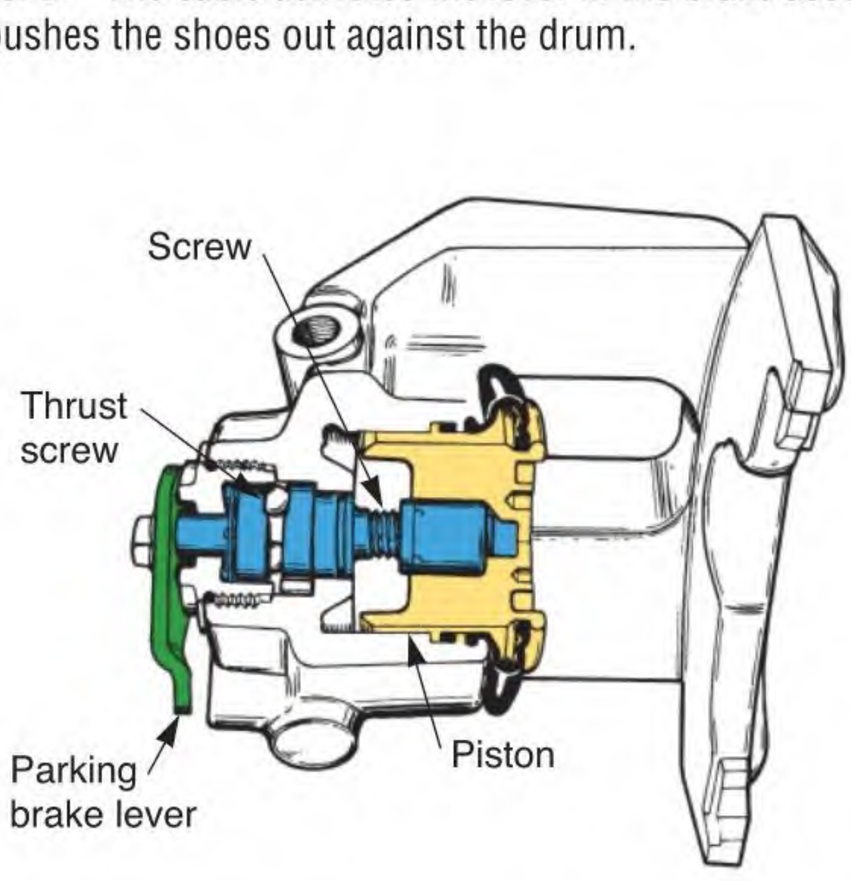
As discussed, today's hybrid vehicles are equipped with regenerative braking systems. These electric braking systems work with the conventional hydraulic brakes to slow the vehicle, while at the same time generating electricity to recharge the vehicle's HV battery.

When the brakes are applied, a brake pedal sensor sends a signal to the hybrid control module, prompting the motor-generator to operate as a generator. With moderate brake pedal pressure, the conventional hydraulic brakes do not apply the friction pads into the spinning brake discs. Instead, the motor-generator places a drag on the rotating tires, wheels, and drive train, slowing the vehicle. If the hybrid vehicle is slowed carefully, almost all the kinetic energy of the moving vehicle is recaptured as electrical energy and forced into the HV battery. This electrical energy is stored in the HV battery and is used to re-accelerate the vehicle from its next full stop.



Green Tech

Volatile Organic Compounds (VOCs)



Volatile organic compounds (VOCs) are toxic substances that evaporate into the atmosphere. VOCs may develop into such environmental hazards as smog, but they are also harmful if kept indoors. VOCs are associated with mild and severe health concerns. VOCs may be found in substances like cleaning solutions, as well as paints or coatings. You can reduce your VOC output by choosing alternatives to VOC-containing products. For example, you can use more environmentally friendly VOC-free brake cleaning solutions.

Summary

- Automotive brakes provide a means of using friction to either slow down, stop, or hold the wheels of the vehicle.
- A brake pedal assembly is a foot lever for operating the master cylinder and power booster.
- A master cylinder is a hydraulic piston-type pump that develops pressure for the brake system.
- A brake booster is a vacuum or power steering operated device for assisting brake pedal application.
- Brake lines are metal tubing and rubber hose for transmitting pressure to wheel brake assemblies.
- Wheel brake assemblies are devices that use system pressure to produce friction for slowing or stopping wheel rotation.
- Braking ratio refers to the comparison of front wheel to rear wheel braking effort.
- A hydraulic system is basically a system that uses a liquid to transmit motion or pressure from one point to another.
- The cup and piston in the master cylinder are used to pressurize the brake system.
- The dual master cylinder, also called a tandem master cylinder, has two separate hydraulic pistons and two fluid reservoirs.
- Power brakes use a booster and either engine vacuum, electric pump, or hydraulic pressure to assist brake pedal application.

Copyright Goodheart-Willcox Co., Inc.

- Brake fluid is a specially blended hydraulic fluid that transfers pressure to the wheel cylinders.
- Brake lines and hoses transfer fluid pressure from the master cylinder to the wheel cylinders.
- The piston seal in the caliper prevents pressure leakage between the piston and cylinder.
- The floating caliper disc brake is mounted on two bolts supported by rubber bushings.
- The bleeder screw provides a means of removing air from the brake system.
- The primary brake shoe is the front shoe. It normally has a slightly shorter lining than the secondary shoe.
- The secondary brake shoe is the rear shoe. It has the largest lining surface area.
- A metering valve is designed to equalize braking action at each wheel during light brake applications.
- A proportioning valve is also used to equalize braking action with front disc and rear drum brakes.
- A combination valve is a single unit that functions as a brake warning light switch, a metering valve, and/or a proportioning valve.
- Emergency brakes, also called parking brakes, provide a mechanical means (cable and levers) of applying the brakes.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

anti-rattle clips
atmospheric suspended brake booster
automotive brakes
bleeder screw
brake backing plate
brake booster
brake caliper
brake disc
brake drum
brake fluid
brake hoses
brake lines
brake pads
brake pad linings
brake pedal assembly
brake rotor
brake shoe adjusters
brake shoes
brake warning light switch
braking ratio

Activities

1. Identify the type of brake system—disc or drum—on a vehicle assigned by your instructor.
2. Examine the calipers of a disc brake system and identify the type: floating or fixed.
3. Using **Figure 80-1**, explain to your class the function of the various parts of a brake system.
4. Using a small hydraulic jack, explain and demonstrate the principle of the hydraulic brake.

Copyright Goodheart-Willcox Co., Inc.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List and explain the six basic parts of a brake system.
2. Describe the four major parts of a disc brake assembly.
3. Which of the following is *not* part of a drum brake assembly?
   (A) Wheel cylinder.
   (B) Booster.
   (C) Shoes.
   (D) Drum.
4. A(n) _____ system uses a liquid to transmit motion or pressure from one part to another.
5. What are four functions of a master cylinder?
6. Why is a dual master cylinder used?
7. A certain automotive brake system's residual pressure valve maintains residual fluid pressure of 9 psi. What is the purpose of this residual pressure?
   (A) To keep the brakes partially engaged at all times.
   (B) To prevent contaminants from entering the system.
   (C) To equalize braking action at each wheel.
   (D) To prevent wheel lockup during heavy brake applications.
8. A power brake vacuum _____ uses engine vacuum to apply the hydraulic brake system.
9. A hydro-boost power brake system uses pressure from the power steering pump. True or False?
10. In a diagonally split brake system, each master cylinder cup and piston assembly operates a brake assembly on opposite sides and corners of the vehicle. True or False?
11. Which of the following is *not* part of a brake caliper?
    (A) Piston seal.
    (B) Bleeder screw.
    (C) Piston boot.
    (D) Cup expander.
12. What causes a brake caliper piston to retract away from the disc after brake application?
13. Why are floating and sliding calipers more common than fixed calipers?
14. The _____ _____ provides a means of removing air from the wheel cylinder after repairs.
15. Explain the difference between a primary brake shoe and a secondary brake shoe.
16. The brake _____ _____ _____, also called the _____ _____ _____, warns the driver of a pressure loss on one side of a dual brake system.
17. Why is a metering valve used?
18. How does a proportioning valve equalize braking action?
19. Describe a combination valve.
20. How does the parking brake work?

ASE-Type Questions

1. Technician A says an automotive master cylinder is a device that uses brake system pressure to produce friction for stopping wheel rotation. Technician B says an automotive master cylinder holds the wheel cylinder piston and brake pads. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says certain automobiles are equipped with disc brakes on all four wheels. Technician B says disc brakes are most commonly used on an automobile's rear wheels. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. All of the following are basic components of an automotive disc brake assembly, *except:*
   (A) rotor.
   (B) brake drum.
   (C) brake pads.
   (D) caliper.
4. Technician A says a caliper cylinder holds the piston on a drum brake assembly. Technician B says a caliper cylinder holds the piston on a disc brake assembly. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

5. Technician A says a hydraulic system uses air to transmit motion or pressure from one point to another. Technician B says a hydraulic system uses a liquid to transmit motion or pressure from one point to another. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says a manual master cylinder normally bolts to the side of the engine. Technician B says a manual master cylinder normally bolts to the engine firewall. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says a push rod connects the brake pedal to the master cylinder piston. Technician B says a steel plate connects the brake pedal to the master cylinder piston. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says an automotive master cylinder keeps the brake system full of fluid as the brake linings wear. Technician B says an automotive master cylinder maintains a slight amount of pressure to keep contaminants from entering the brake system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says a master cylinder's cup and piston are used to release brake system pressure. Technician B says a master cylinder's cup and piston are used to pressurize the brake system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says a dual master cylinder's rear piston assembly is called the primary piston. Technician B says a dual master cylinder's rear piston assembly is called the secondary piston. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. Technician A says certain automotive power brake systems use engine vacuum to assist brake pedal application. Technician B says certain automotive power brake systems use a vacuum pump to assist brake pedal application. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. Technician A says an automotive brake booster is a piston-type pump that develops pressure for the vehicle's brake system. Technician B says an automotive brake booster is a vacuum or power steering–operated device that assists brake pedal application. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. Technician A says an atmospheric suspended vacuum brake booster works on both sides of the diaphragm or piston. Technician B says a vacuum suspended booster works on both sides of the piston or diaphragm. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. Technician A says a "longitudinally split" brake system has each master cylinder piston operating the brake assemblies on opposite corners of the vehicle. Technician B says a "longitudinally split" brake system has one master cylinder piston operating the front wheel brake assemblies and the other piston operating the rear wheel brake assemblies. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
15. A combination valve functions as all of the following, *except:*
    (A) proportioning valve.
    (B) warning light switch.
    (C) fluid level sensor.
    (D) metering valve.

Chapter 81
Brake System Diagnosis, Service, and Repair

After studying this chapter, you will be able to:

- Diagnose common brake system problems.
- Inspect and maintain a brake system.
- Explain how to service a disc brake assembly.
- Explain how to service a drum brake assembly.
- Describe basic procedures for servicing a master cylinder and a brake booster.
- Describe the procedures for manual, pressure, and vacuum bleeding of a brake system.
- Cite the safety rules that should be followed when servicing brake systems.
- Correctly answer ASE certification test questions about the diagnosis and repair of brake systems.

The brake system is the most important system on a vehicle from a safety standpoint. The customer trusts the technician to do every service and repair operation correctly because his or her life may depend upon it.

When working on a brake system, always keep in mind that a brake system failure could result in a deadly automobile accident. It is up to you to make sure the vehicle's brake system is in perfect operating condition before releasing the vehicle to the customer.

This chapter will explain the most important procedures to follow when servicing automotive brakes, including pads, shoes, discs, drums, wheel cylinders, calipers, and hydraulic valves. The next chapter explains the operation, diagnosis, and repair of anti-lock brake systems.

Brake System Problem Diagnosis

Use brake symptoms (noises, smells, abnormal brake pedal movements, improper braking action, etc.) when diagnosing brake system problems. Listen to the customer's complaints or the service writer's explanation. Then, inspect the brake system or test-drive the vehicle.

It is important that you be able to interpret the symptoms. You can then decide what adjustments or repairs are needed. Refer to **Figure 81-1**.

Almost all brake system problems can be sorted into the following basic categories: brake pedal vibration, grabbing brakes, excessive brake pedal effort, pulling brakes, spongy brake pedal, dropping brake pedal, low brake pedal, dragging brakes, no brake pedal, illuminated brake warning light, and braking noise.

Copyright Goodheart-Willcox Co., Inc.

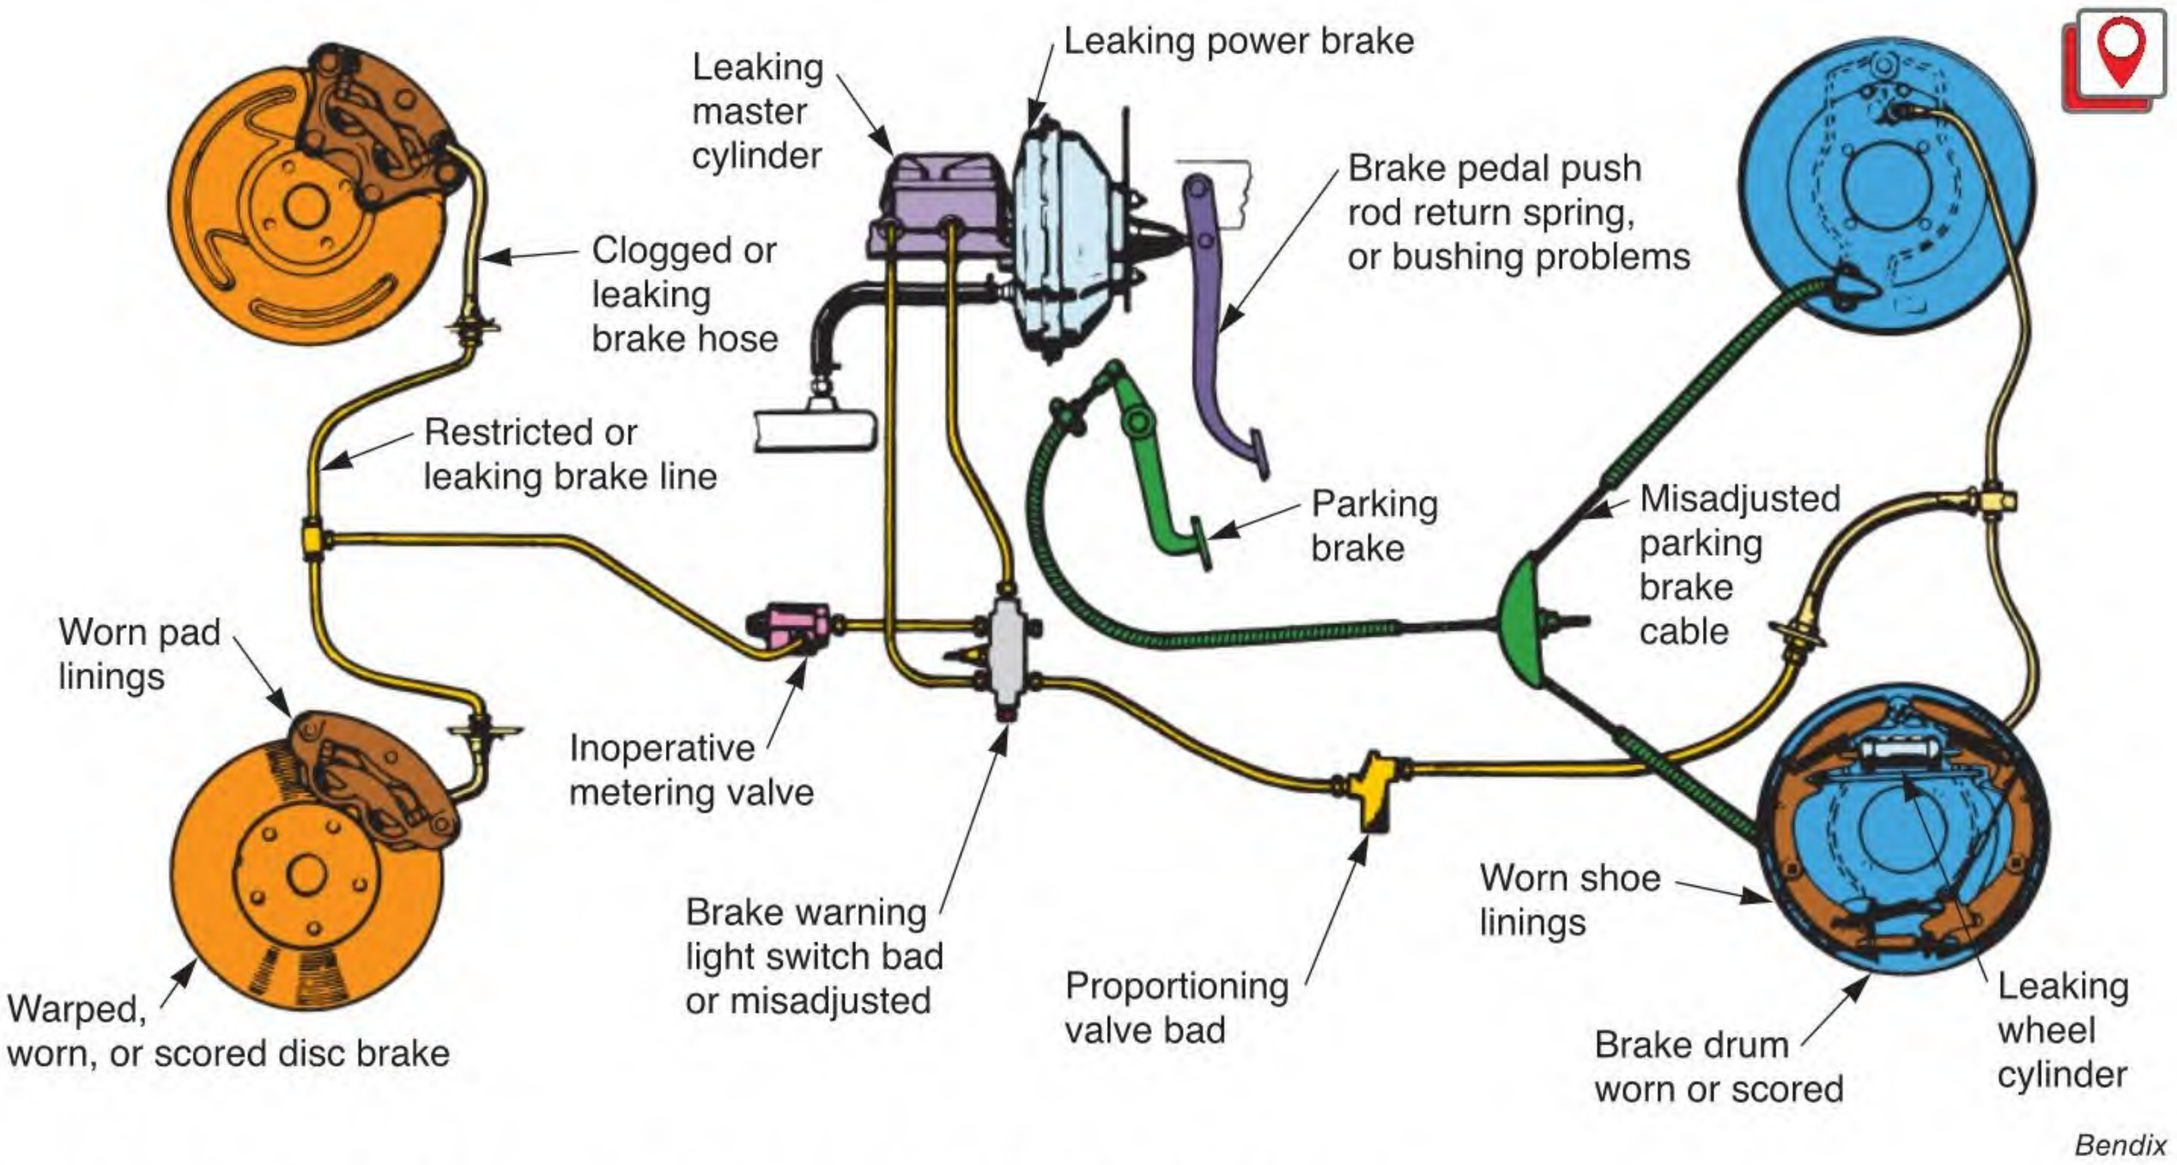

Figure 81-1. Note some of the common problems that can develop in a brake system.

Brake System Diagnostics

Modern brake systems, primarily those with anti-lock brake systems, have self-diagnostic capabilities. If the brake control module detects an abnormal operating condition in a circuit, it will store one or more diagnostic trouble codes and illuminate a malfunction indicator light in the dash. You can then scan the brake system to retrieve the stored trouble codes. These codes will indicate which brake circuit or component is causing the problem.

Tech Tip

Remember that vibration problems caused by a defective tire or a bent wheel are present whenever the vehicle is moving and are usually more pronounced at a specific speed. Brake vibration problems, on the other hand, are only present when the brakes are applied.

Brake Vibration

Brake vibration shows up as a chatter, pulsation, or shake problem when the brake pedal is pressed. The vibration may be felt mostly in the steering wheel (front brake assembly problems) or in the brake pedal itself (could be problems at any wheel). When problems are severe, the whole chassis and body (hood and fenders) may vibrate when braking. Brake vibration is usually caused by a warped brake disc or an out-of-round brake drum. Hard spots on the disc or drum can also cause vibration.

Grabbing Brakes

Grabbing brakes apply too quickly, even with light brake pedal application. If the brakes are grabbing, it will be very difficult to stop slowly.

Grabbing is usually caused by a malfunctioning brake booster, brake fluid or grease on the linings, worn brake linings, a faulty metering valve, or a mechanical problem in the wheel brake assembly.

Excessive Brake Pedal Effort

Excessive brake pedal effort is a noticeable increase in the amount of foot pressure needed to apply the brakes. It can be caused by a variety of problems, such as a frozen wheel cylinder or caliper

Copyright Goodheart-Willcox Co., Inc.

piston, a clogged brake hose or line, a faulty master cylinder, contaminated linings, a disconnected brake booster vacuum line, or a defective brake booster.

Pulling Brakes

Pulling brakes cause the vehicle to veer to the right or left when the brakes are applied. When the problem is in the front brakes, a strong pulling force will be noticed on the steering wheel. Rear brake pull is only noticeable during very hard braking—one of the rear brakes will lock up, causing tire skid and squeal.

Brake pull is usually caused by a frozen caliper or wheel cylinder piston, a grease- or fluid-coated lining, a leaking cylinder, a faulty automatic adjuster, or a buildup of brake lining dust. Incorrect front end alignment can also make the vehicle pull to one side during braking.

Spongy Brake Pedal

A ***spongy brake pedal*** feels like it is connected to a spring or a rubber band. The brakes will apply, but the pedal does not feel solid. It will travel farther toward the floor before full braking action occurs.

This condition is usually caused by air in the brake system. The air is compressing, so it takes up less space. A spongy pedal can also result from faulty residual pressure check valves in the master cylinder or maladjusted brake shoes.

Dropping Brake Pedal

A ***dropping brake pedal*** slowly moves all the way to the floor when steady pressure is applied to it. This condition usually shows up when the driver is stopped at a stoplight. The brake may apply normally at first. However, while holding the brakes, the pedal steadily creeps downward. Pumping usually restores pedal height momentarily.

A dropping brake pedal is usually caused by an internal leak in the master cylinder. Pressure is slowly leaking past the piston cups. Since fluid returns to the reservoir, the fluid level will not drop.

A fluid leak anywhere else in the system can also cause the same symptom. If fluid is leaking out, however, the fluid level in the master cylinder will drop.

Low Brake Pedal

A ***low brake pedal*** travels too far toward the floor before braking. The pedal is not spongy, and braking is normal once the pedal applies the brakes.

A low brake pedal can be caused by inoperative brake adjusters, a maladjusted master cylinder push rod, or a mechanical problem in the wheel brake assemblies.

Dragging Brakes

Dragging brakes remain partially applied when the brake pedal is released. The brakes will overheat if the vehicle is driven very far. To detect dragging brakes, feel each wheel assembly. The dragging brake or brakes will be abnormally hot.

Dragging brakes can be caused by frozen wheel cylinder pistons, an overadjusted parking brake, weak return springs, an overadjusted master cylinder push rod, brake fluid contamination, or a master cylinder problem.

No Brake Pedal

No brake pedal is a dangerous condition in which the brake pedal moves to the floor with no braking action. Pumping the brakes does not help.

Lack of braking action is usually caused by a hydraulic problem. A system leak may have emptied the master cylinder reservoir.

With today's dual master cylinders, a complete loss of braking is unlikely. However, it can occur from driver neglect.

Brake Warning Light On

When the ***brake warning light*** is on, it indicates either an internal leak (master cylinder) or an external leak (brake line, hose, wheel cylinder) in the hydraulic system. Unequal pressure in the dual master cylinder system has caused the warning light switch (usually part of combination valve) to shift to one side. Inspect the system for leaks and check the action of the master cylinder.

Braking Noise

Braking noise can be grinding sounds, squeaks, rattles, and other abnormal noises. Use your understanding of system operation to determine the cause of braking noise.

A brake grinding sound is a metal-on-metal noise that occurs only when braking may be due to worn brake linings. The shoe or pad may be rubbing on the metal drum or brake disc.

A squeak when braking may be caused by glazed (hardened) brake linings, an unlubricated brake drum

Copyright Goodheart-Willcox Co., Inc.

backing plate, foreign material embedded in the linings, or a wear indicator rubbing on a rotor.

A brake rattle may be due to a missing anti-rattle clip or disconnected spring on the brake caliper assembly. Loose or disconnected parts in the drum brake assembly can also cause a rattle from inside the brake assembly.

Brake System Inspection

Most automobile manufacturers recommend a periodic inspection of the brake system. The inspection is a form of preventive maintenance that helps ensure safety. During a brake system inspection, you should:

- Check the fluid level in the master cylinder. Low brake fluid indicates excessive pad and/or brake disc wear or fluid leaking out of the system.
- Check brake pedal action while parked and while driving.
- Check for abnormal sounds when braking.
- Inspect the brake lines, hoses, and wheel brake assemblies, **Figure 81-1**.

Checking Brake Pedal Action

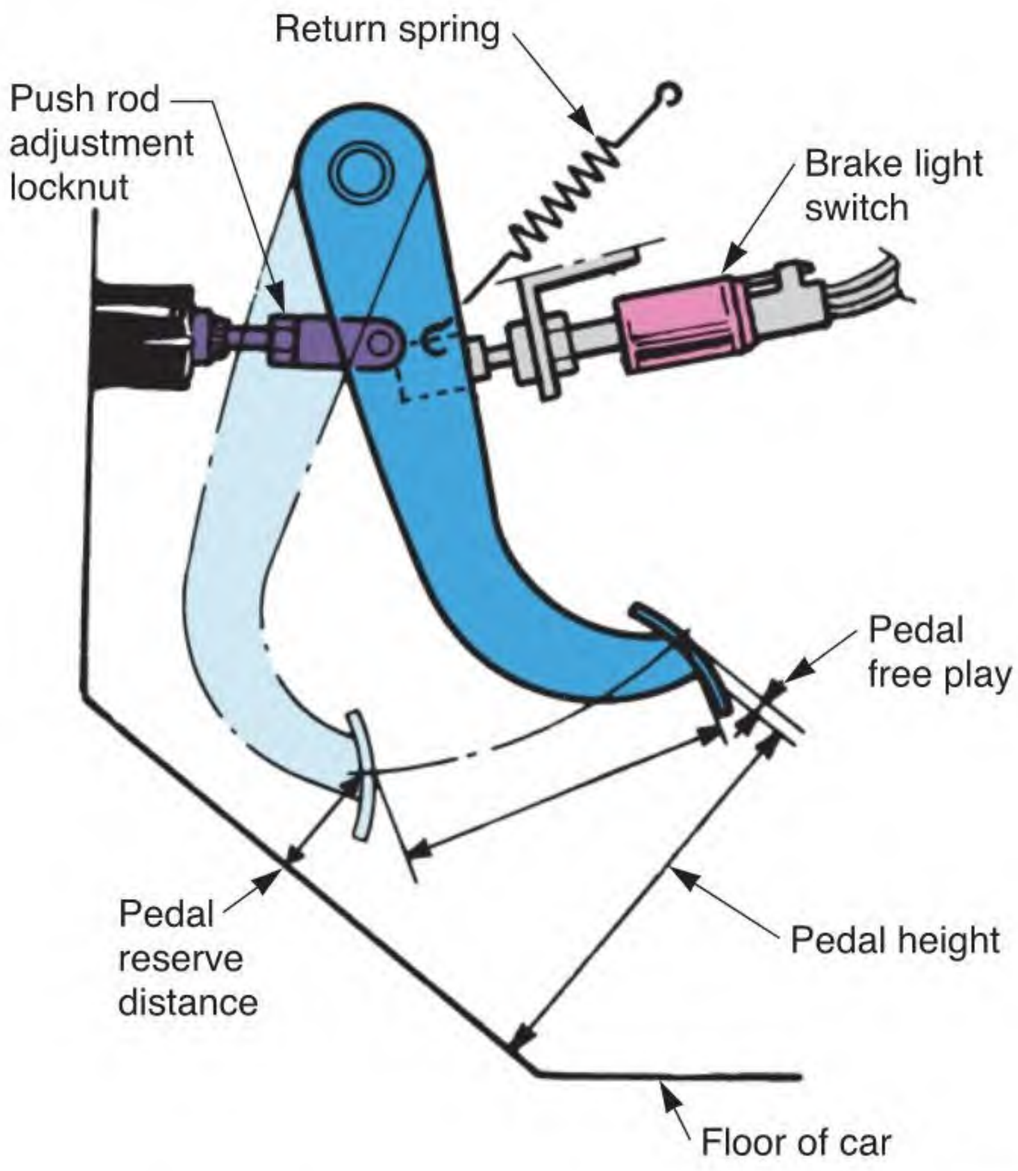
A fast and accurate way of checking many components of the brake system is the ***brake pedal check***. This is done by applying the brake pedal and comparing its movement to specifications. There are three brake pedal application specifications (distances): pedal height, pedal free play, and pedal reserve distance.

Brake pedal height is the distance from the pedal to the floor with the pedal fully released. Incorrect pedal height is usually caused by problems in the pedal mechanism. There may be worn pedal bushings, a weak return spring, or a maladjusted master cylinder push rod.

Brake pedal free play is the amount of pedal movement before the beginning of brake application. It is the difference between the "at rest" position and the initially applied position.

Brake pedal free play is needed to prevent brake drag. If pedal free play is not correct, check the adjustment of the master cylinder push rod. A worn pedal bushing or a bad return spring can also increase pedal free play.

Brake pedal reserve distance is measured from the vehicle's floor to the brake pedal when the brakes are applied. Typically, brake pedal reserve distance should be 2″ (51 mm) for manual brakes and 1″ (25 mm) for power brakes. See **Figure 81-2**.



If brake pedal reserve distance is incorrect, check push rod adjustment. Also, check for air in the system or inoperative brake adjusters. Numerous other problems can cause incorrect pedal reserve distance.

When checking brake pedal action, apply and hold the brake pedal firmly for about 15 seconds. The engine should be running if the vehicle has power brakes. Try to detect any system leakage, which would cause the pedal to slowly move toward the floor. Also, make sure the pedal is firm and that it returns properly.

While checking the brake pedal, you should also make sure the brake lights are operating. If they do not work, check the bulbs, the fuses, and the switch.

Checking Brake Fluid

An important part of a brake system inspection involves checking the level and condition of the brake fluid. To check the fluid, remove the master cylinder cover. Pry off the spring clips and lift off the lid or cover. Be careful not to drip brake fluid on the car's paint. Wipe off brake fluid spills right away or they will dissolve the paint and require a major auto body repair.

Honda

Figure 81-2. Note the basic brake pedal measurements. Brake pedal height, reserve distance, and free play are important. Some vehicles have an adjustable push rod. Also note the location of the brake light switch.

Copyright Goodheart-Willcox Co., Inc.

Typically, the ***brake fluid level*** should be 1/4″ (6 mm) from the top of the master cylinder reservoir. Add the correct type of brake fluid as needed.

Tech Tip

Only use the manufacturer's recommended type of brake fluid. Also, keep oil, grease, and other substances out of the brake fluid. Contamination can cause rapid deterioration of the master cylinder cups, resulting in a sudden loss of braking ability.

Checking for Brake System Leaks

When the fluid level in the master cylinder is low, you should inspect the brake system for leaks. Check all brake lines, hoses, and wheel cylinders for wetness and the smell of brake fluid. Brake fluid leakage will show up as a darkened, damp area around brake hoses and line fittings, master cylinder, metering valves, wheel cylinders (bottom of drums), or calipers (at piston boots).

Checking the Parking Brake

Apply the parking brake. The pedal or lever should not move more than 2/3 of full travel. The parking brake should keep the vehicle from moving with the engine idling and the transmission in drive.

The parking brake cables and linkage should also be inspected. The cables should not be frayed. The linkage should be tight, undamaged, and well lubricated.

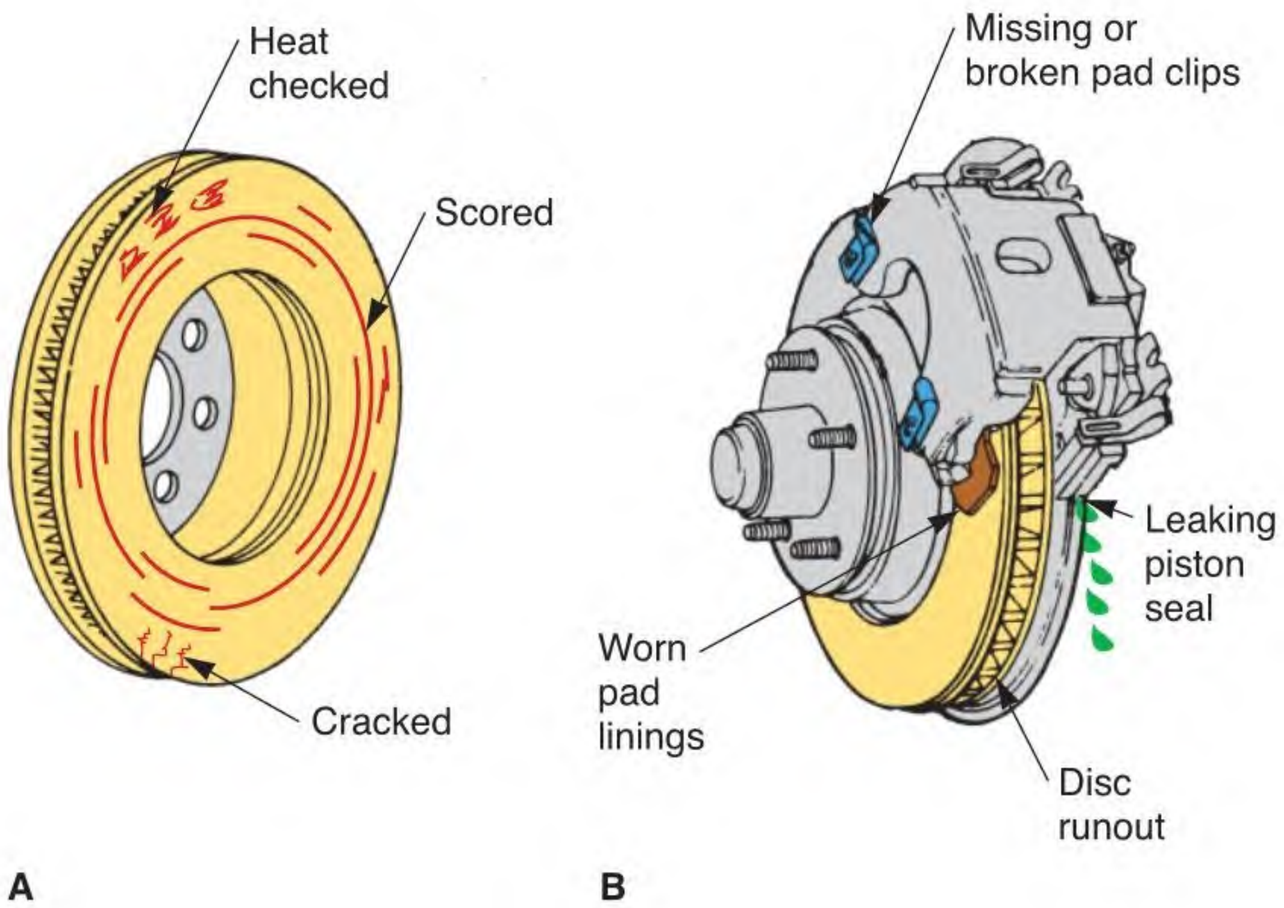
Checking Wheel Brake Assemblies

When inspecting a brake system, remove one front wheel and one rear wheel. This will let you inspect the condition of the brake linings and other wheel brake assembly components.

When inspecting disc brakes, check the thickness of the brake pad linings. Pads should be replaced when the thinnest (most worn) part of the lining is no thicker than the metal shoe (approximately 1/8″ or 3 mm). **Figure 81-3** shows common disc brake problems. Study them closely.

Check the caliper piston for fluid leakage and inspect the brake disc for damage. The disc should not be scored, cracked, or ***heat checked*** (small hardened and cracked areas caused by overheating). The wheel bearings should be adjusted properly. To check for rattles, strike the caliper with a rubber mallet. Repair any problems according to service manual instructions.

When inspecting drum brakes, you must remove the brake drum. This will expose the brake shoes, the wheel cylinder, the braking surface of the drum, the adjuster mechanism, and other parts, **Figure 81-4**.



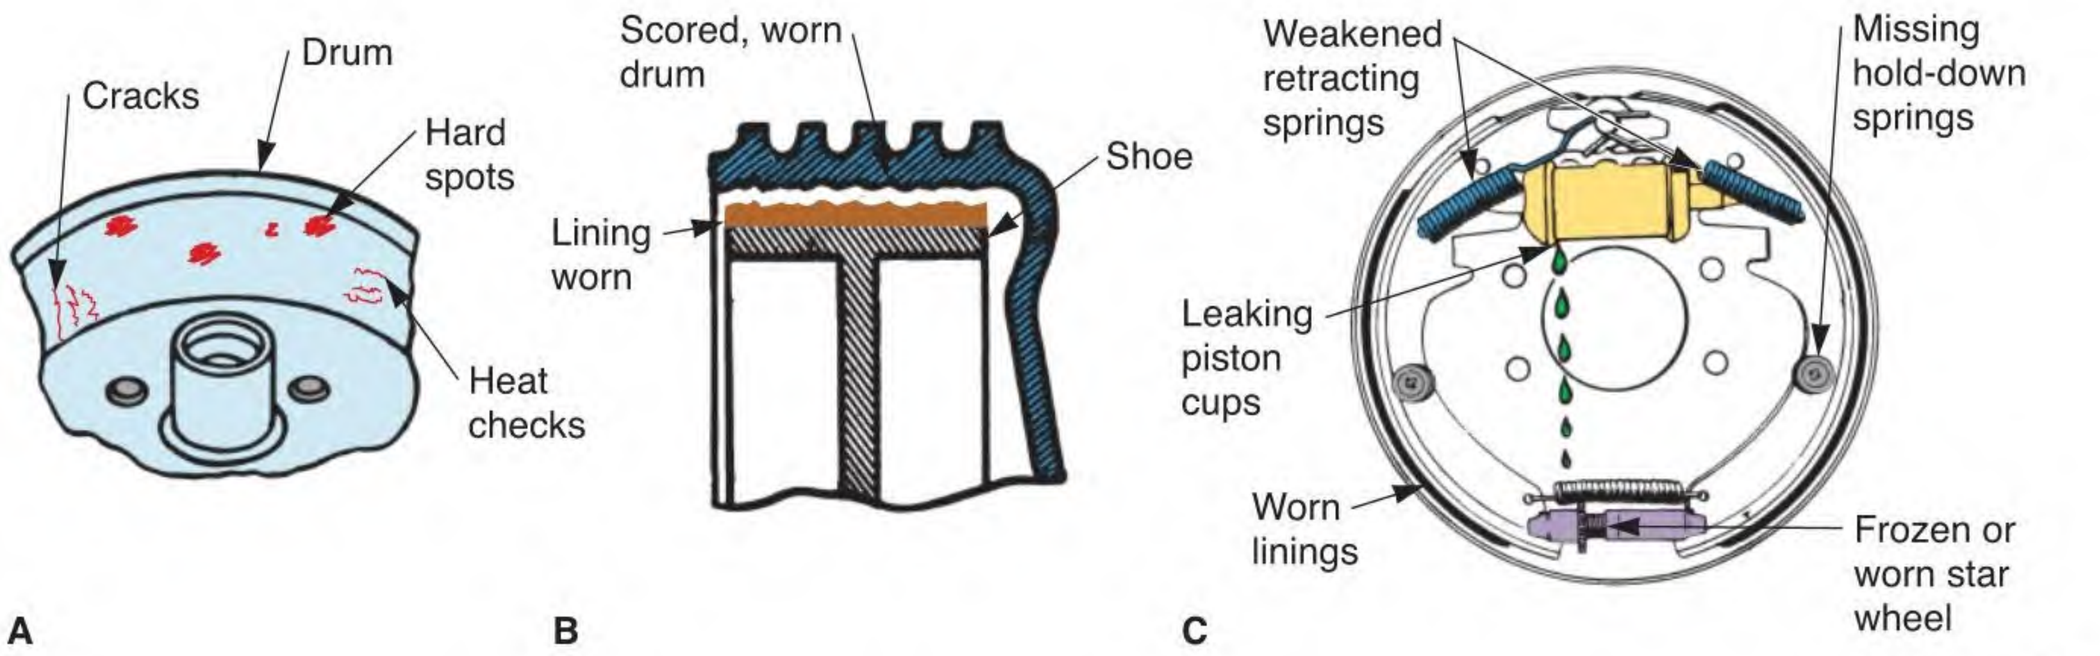


Figure 81-3. Study these disc brake problems. A—Check the rotor for heat checking, cracks, and scoring. B—Also check for a leaking piston seal, worn pad linings, and missing clips.

Copyright Goodheart-Willcox Co., Inc.

Bendix and FMC

Figure 81-4. Study these common drum brake problems. A—Check the drum for cracks, heat checks, and hard spots. B—A badly scored drum must be machined. If the drum is worn too much, it must be replaced. C—Check for a leaking wheel cylinder, worn linings, and missing or damaged parts.

The brake shoe linings must never be allowed to wear thinner than approximately 1/16″ (1.5 mm). The shoes should not be glazed or coated with brake fluid, grease, or differential fluid. Any of these problems requires lining replacement. If the linings are contaminated with brake fluid or other substances, the cause of the contamination must be corrected before the linings are replaced.

Pull back the wheel cylinder boots and check for leakage. If the boot is full of fluid, the wheel cylinder should be rebuilt or replaced. Also, check the automatic adjuster, the return springs, and the brake drum. The brake drum should not be scored, cracked, heat checked, or worn beyond specifications.

Warning

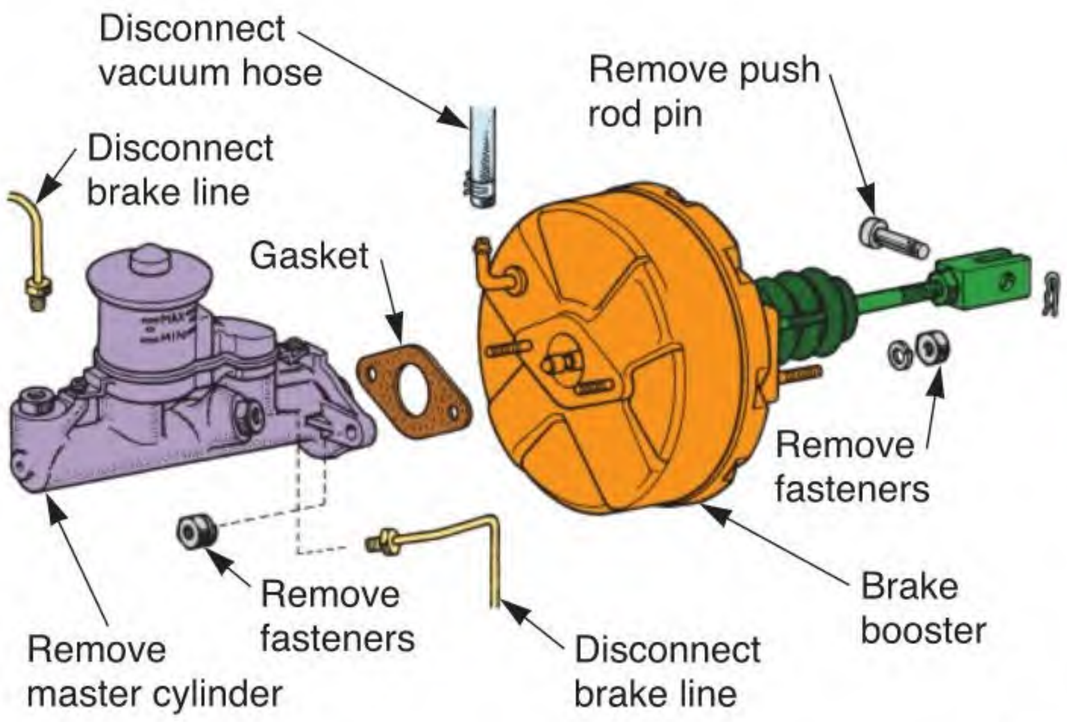
Take every precaution to avoid breathing brake lining dust. If needed, wear an approved filter mask over your nose and mouth. Never use compressed air to blow brake dust off a wheel brake assembly. Use a special brake vacuum and a clean rag to remove the dust. Older brake linings were made of asbestos, a known cancer-causing substance. Newer linings are made from safer materials, but the brake dust created by these substances can be harmful to your health.

Vacuum Booster Service

If a vehicle has vacuum-type power brakes, you should inspect the brake booster and the vacuum hose. Make sure the vacuum hose from the engine is in good condition. It should not be hardened, cracked, or swollen. Also, check the hose fitting in the booster.

To test the vacuum booster, pump the brake pedal several times to remove any vacuum from the booster. Then, press down lightly on the brake pedal as you start the engine. If the vacuum booster is functioning, the brake pedal will move downward slightly as soon as the engine starts.

Many shops do not rebuild vacuum brake boosters. Instead, they install a new or factory rebuilt unit. Some boosters are sealed and cannot be disassembled. **Figure 81-5** shows the parts that must be removed when replacing a vacuum booster.



A vacuum brake booster rebuild normally involves replacing the diaphragm, the valves, and other plastic or rubber parts. Refer to a service manual for exact procedures for a particular booster.

Hydraulic Booster Service

A hydraulic brake booster should be checked when inspecting a brake system. Check all the hydraulic lines for signs of leakage. Tighten connections or replace any line that leaks.

If the booster is inoperative, check the fluid level in the power steering pump. A low fluid level can prevent hydro-boost operation. When the hydraulic booster is found to be faulty, it should be replaced. Most types are not repairable.

Copyright Goodheart-Willcox Co., Inc.

Toyota

Figure 81-5. These components may need to be removed for service of the master cylinder and brake booster.

Master Cylinder Service

A faulty master cylinder usually leaks fluid past the rear piston or leaks internally. When fluid is leaking past the rear piston, you should find brake fluid in the rear boot or on the firewall. When the leak is internal, the brake pedal will slowly sink to the floor as pressure is applied. Inoperative valves in the master cylinder are also a reason for service.

Master Cylinder Removal

To remove a master cylinder, disconnect the brake lines from the master cylinder using a tubing wrench. Then, unbolt the master cylinder from the brake booster or the firewall. Sometimes, the push rod must be disconnected from the brake pedal assembly.

Master Cylinder Rebuild

Many shops simply replace a faulty master cylinder with a new or factory rebuilt unit. A replacement cylinder may be cheaper than the cost of labor and parts for an in-shop rebuild. Further, the new or factory rebuilt master cylinder will have a remachined cylinder and a guarantee.

To rebuild a master cylinder, drain the fluid from the reservoir. Then, completely disassemble the unit, following the manufacturer's instructions. Basically, you must hone the cylinder and replace the piston cups and valves. Clean the parts in brake fluid before reassembly.

Caution

Do not clean the hydraulic parts of a brake system with conventional parts cleaners. These cleaners can destroy the special rubber cups in the brake system. Use only brake fluid or a manufacturer-suggested cleaner (denatured alcohol for example).

After cleaning, measure the piston-to-cylinder clearance. Use a telescoping gauge and an outside micrometer or a strip-type feeler gauge. The cylinder must not be tapered or worn beyond specifications. Also, make sure the cylinder is not corroded, pitted, or scored. Replace the master cylinder if the cylinder is not in perfect condition after honing.

Blow all parts dry with compressed air. Blow out the ports and check that they are unobstructed. Lubricate the parts with brake fluid. Assemble the unit according to the manufacturer's instructions.

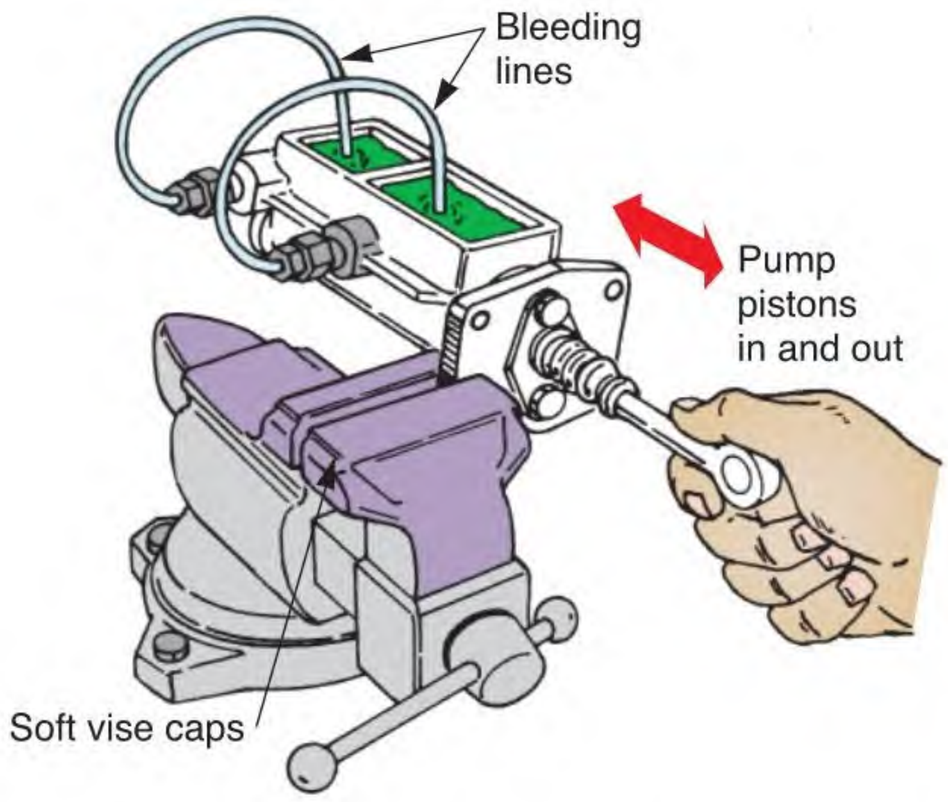
Bench Bleeding a Master Cylinder

Bench bleeding removes air from inside the master cylinder. This must be done before installing the unit on the vehicle.

Mount the master cylinder in a vise. Install short sections of brake line and bend them into each reservoir. Fill the reservoirs with approved brake fluid. Then, pump the piston in and out by hand until air bubbles no longer form in the fluid, as shown in **Figure 81-6**.

Installing a Master Cylinder

To install a master cylinder, replace the reservoir cover after bench bleeding. Bolt the master cylinder to the firewall or booster. Check the adjustment of the push rod if a means of adjustment is provided.



Without cross-threading the fittings, screw the brake lines into the master cylinder. Lightly snug the fittings. Then, bleed (remove air from) the system.

Tighten the brake line fittings. Top off the reservoir with fluid and check brake pedal feel. Test-drive the vehicle to verify your repairs.

Brake System Bleeding

The brake system must be free of air to function properly. Air in the system will compress, causing a spongy brake pedal. Air can enter the system any time a hydraulic component (brake line, hose, master cylinder, wheel cylinder, etc.) is disconnected or removed.

Copyright Goodheart-Willcox Co., Inc.

EIS

Figure 81-6. Before installing a new or rebuilt master cylinder, bench bleed the unit. Fill the reservoir with brake fluid and install bleeding lines. Then pump the piston in and out until no air bubbles are visible in the reservoir.

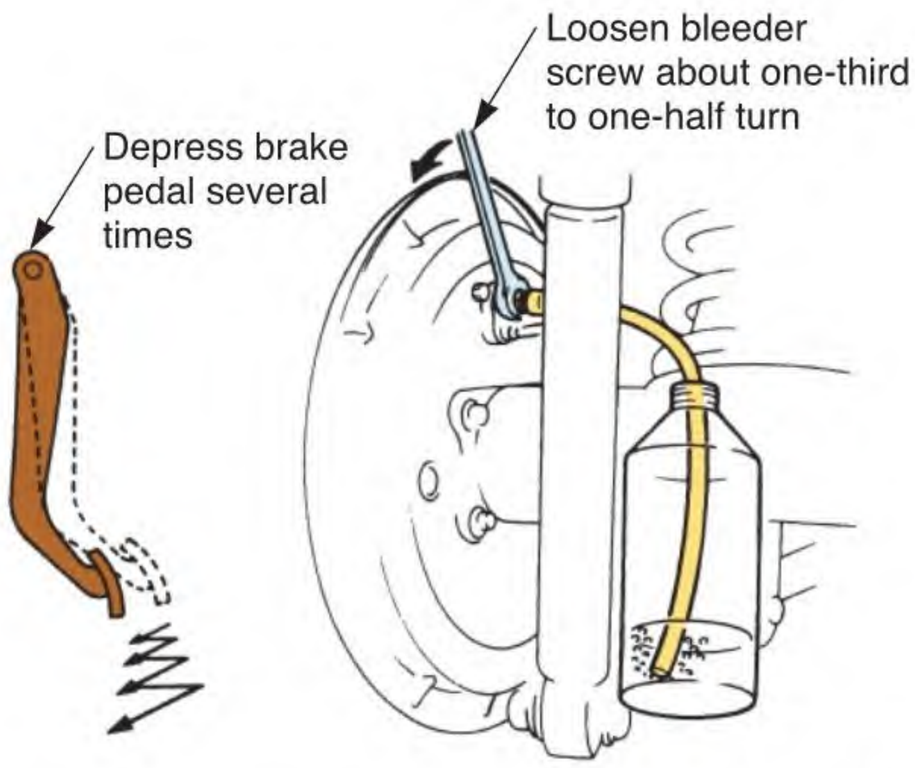
Brake system bleeding involves the use of fluid pressure to force air out of the brake line connections or wheel cylinder bleeder screws. There are three methods of bleeding brakes: manual bleeding, pressure bleeding, and vacuum bleeding.

Manual Bleeding

Manual bleeding is accomplished by using master cylinder pressure to force fluid and trapped air out of the system.

Service Procedure

To manually bleed a brake system:



1. Attach one end of a hose to the bleeder screw.
2. Place the other end of the hose in a jar partially filled with clean brake fluid. Make sure the end of the hose is submersed in the fluid.
3. Have another technician gently depress the brake pedal.
4. Open the bleeder screw or fitting on the caliper or wheel cylinder while watching for air bubbles at the hose.
5. Close the bleeder screw or fitting and tell your helper to release the brake pedal.
6. Repeat steps 3–5 until no air bubbles come out of the hose.
7. Perform this operation on the other wheel brake assemblies or at brake line connections, if needed.

Typically, start bleeding at the wheel brake assembly farthest from the master cylinder and work your way toward the master cylinder. Some brake systems require special procedures when bleeding. When in doubt, refer to the vehicle's service manual. See **Figure 81-7**.

Brake line fittings that are higher than the bleeder screws can sometimes trap air. By loosening these line fittings, you can bleed more air out of the system.

Tech Tip

Check the manufacturer's instructions for details when in doubt. For example, for certain systems you may need to push or pull out the metering valve stem before bleeding the brake system.

Goodheart-Willcox Publisher

Figure 81-7. If you are not using a pressure bleeder, you can have a helper pump the brake pedal up and down lightly to build system pressure. Then, crack open the bleeder screw to purge air from the system. A container of brake fluid will keep air from being pulled back into the system.

Copyright Goodheart-Willcox Co., Inc.

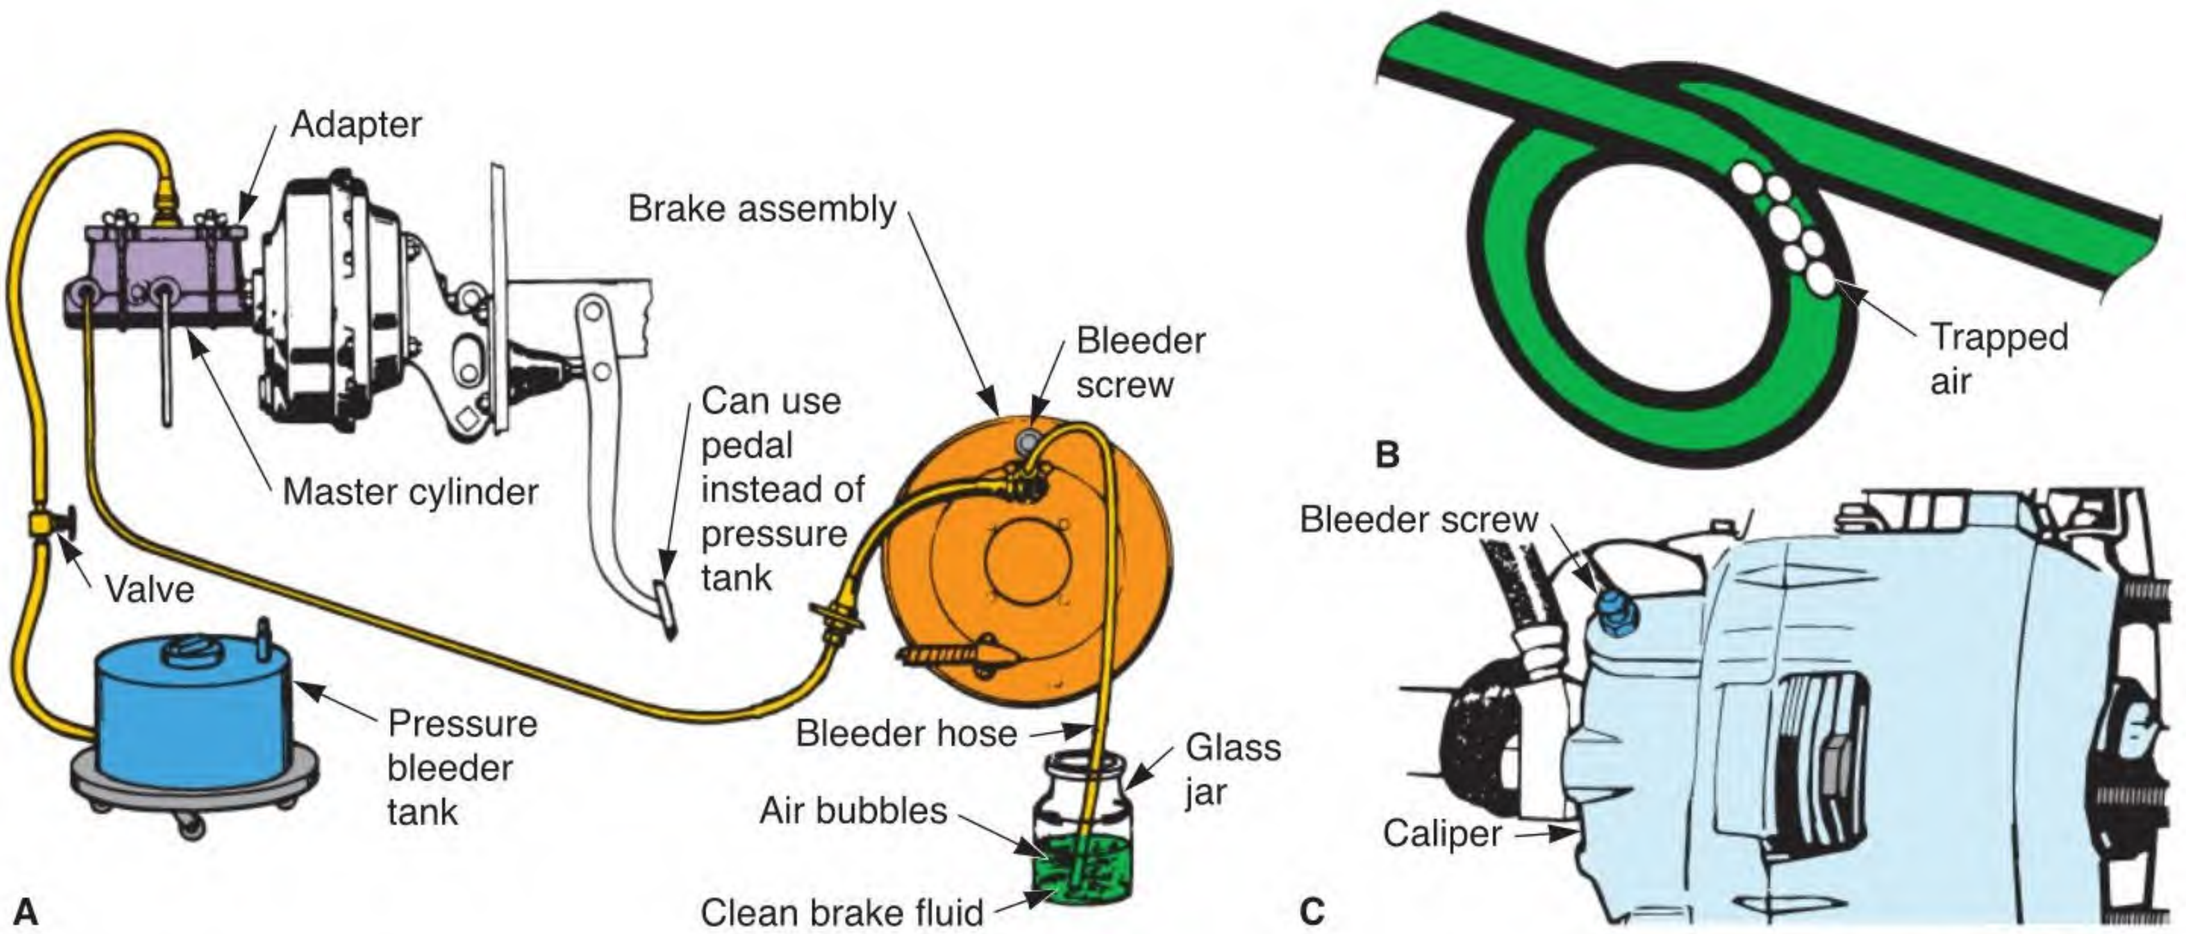
Pressure Bleeding

Pressure bleeding a brake system is done using a pressure bleeder tank, which contains brake fluid under pressure. Pressure bleeding is quick and easy because you do not need a helper to work the brake pedal.

A special adapter is installed over the master cylinder reservoir. A pressure hose connects the master cylinder and the pressure tank. A valve in the hose controls flow. See **Figure 81-8**.

Pour enough brake fluid in the bleeder tank to reach the prescribed level. Charge the tank with 10–15 psi (69–103 kPa) of air pressure. Fill the master cylinder with brake fluid. Install the adapter and hose on the master cylinder. Open the valve in the hose. You are now ready to bleed the brakes.

Attach one end of a hose to a bleeder screw and place the other end of the hose in a jar containing clean brake fluid. Open the screw. As soon as the fluid entering the jar is clear, close the screw. Repeat the bleeding operation on the other wheel brake assemblies in the proper order.



Tech Tip

A special pressure bleeding adapter is needed on master cylinders using a plastic reservoir. Use an adapter that seals over the ports in the bottom of the master cylinder. This will prevent reservoir damage.

Vacuum Bleeding

Vacuum bleeding involves using a vacuum device to pull brake fluid through the hydraulic system for flushing or bleeding. A ***vacuum bleeder tool*** uses shop air pressure and the Venturi effect to produce suction in a brake fluid container and a small plastic hose connected to the brake bleeder screw. A knob on the top of the vacuum brake bleeder allows you to adjust airflow and vacuum applied.

An automatic ***master cylinder filling tool*** is used to keep the fluid reservoir full of brake fluid while bleeding or flushing. It has a float valve or ball in its neck that only opens when the fluid in the master cylinder drops too low.

Bendix and Chrysler

Figure 81-8. Pressure bleeding a brake system involves forcing brake fluid through the lines and the wheel brake assemblies. This forces air out of the system. Note how a pressure bleeder is connected to the master cylinder. With pressure in the system, open each bleeder screw until the air is purged from the system. A—Complete setup. B—Trapped air. C—Bleeder screw location.

Copyright Goodheart-Willcox Co., Inc.

Service Procedure

To vacuum bleed a brake system:

1. Fill the master cylinder filling tool with brake fluid and install it on the reservoir, **Figure 81-9A**.
2. Remove protective plastic cap over brake bleeder screw (if applicable) and loosen the screw, **Figure 81-9B**.
3. Install one end of the clear plastic hose over the loosened brake bleeder screw, **Figure 81-9C**, and the other end to the vacuum bleeder tool, **Figure 81-9D**.
4. Connect a shop air hose to the vacuum bleeder tool. Adjust the knob on the tool until brake fluid starts flowing through the clear hose. When new fluid is seen passing steadily through the clear vacuum hose (usually 25–30 seconds), air has been removed from the system.
5. After bleeding a caliper or wheel cylinder, tighten the bleeder screw.
6. Repeat steps 2–5 for each wheel brake assembly following the order given in the service information. Many technicians like to final bleed all air from the system after vacuum bleeding by pressing the brake pedal while cracking open the bleeder screws.

Flushing a Brake System

Brake system flushing is done by pressure bleeding all the old fluid out of the system. Flushing is needed when the brake fluid is contaminated (filled with dirt, rust, corrosion, oil, or water). Bleed each wheel cylinder until clean fluid flows from the bleeder screw or fitting.

Brake Line and Hose Service

Brake lines and hoses can become damaged or deteriorated after prolonged service. When replacing a brake line, use approved double-wall steel tubing. Brake lines normally use double-lap flares. Some common tools and procedures used when servicing brake lines and hoses are shown in **Figure 81-10**.

Disc Brake Service

Complete ***disc brake service*** typically involves four major operations:

- Replacing worn brake pads.
- Rebuilding the caliper assembly.
- Turning (machining) the brake discs.
- Bleeding the system.

Depending on the condition of the disc brake assembly, the technician may need to do one or more of these operations. Service manual procedures and shop policies vary. In any case, you must make sure the brake assembly is in sound operating condition. Refer to **Figure 81-11**.

Replacing Brake Pads

Service Procedure

To replace worn brake pads in a floating caliper:

1. Loosen the wheel lug nuts.
2. Place the vehicle on jack stands or secure it on a lift.
3. Use an impact wrench and socket to remove the tire-and-wheel assemblies.
4. Use a large C-clamp or caliper tool to push each piston back into its cylinder, **Figure 81-12A**.
5. Unbolt the calipers and slide them off the brake discs, **Figure 81-12B**.
6. Hang the calipers by a piece of wire (if the caliper is not to be removed). See **Figure 81-12C**.

Tech Tip

To prevent brake hose damage, do not allow the heavy calipers to hang on their hoses. A metal hose end can cut through the rubber and cause a dangerous pressure leak.

7. Remove the old brake pads from the calipers.
8. Install anti-rattle clips on the new pads. If required, install any adhesive or insulator compound to the recommended surfaces on the metal areas of the pads.

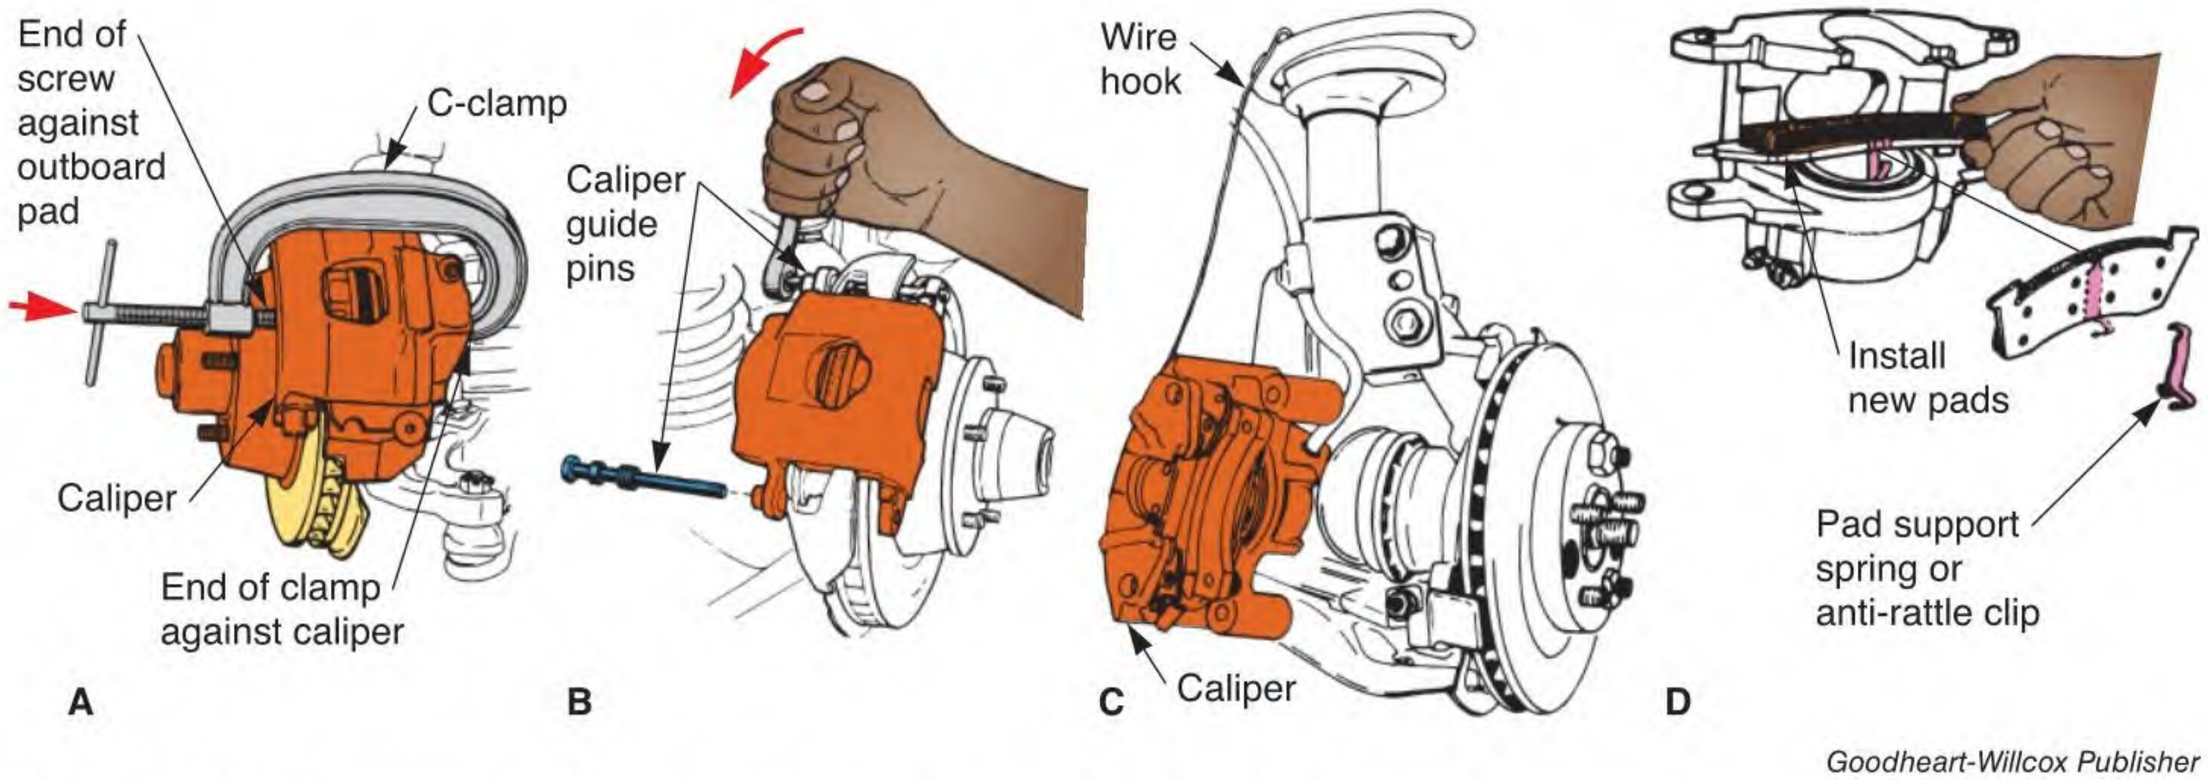

Figure 81-11. On modern vehicles, two bolts commonly hold the caliper on the steering knuckle. The brake hose connects the metal brake line to the caliper.

9. Fit the new pads into the calipers, **Figure 81-12D**. Install any retainer clips on the brake pads during installation.
10. With their pistons fully retracted (pushed inward), slide the caliper assemblies down over the brake discs.
11. Assemble the caliper mounting hardware in reverse order of disassembly.
12. Use a torque wrench to make sure all bolts are torqued properly.
13. Install the wheels and torque the lug nuts or bolts to specifications.
14. Test-drive the car to verify your repairs.

Tech Tip

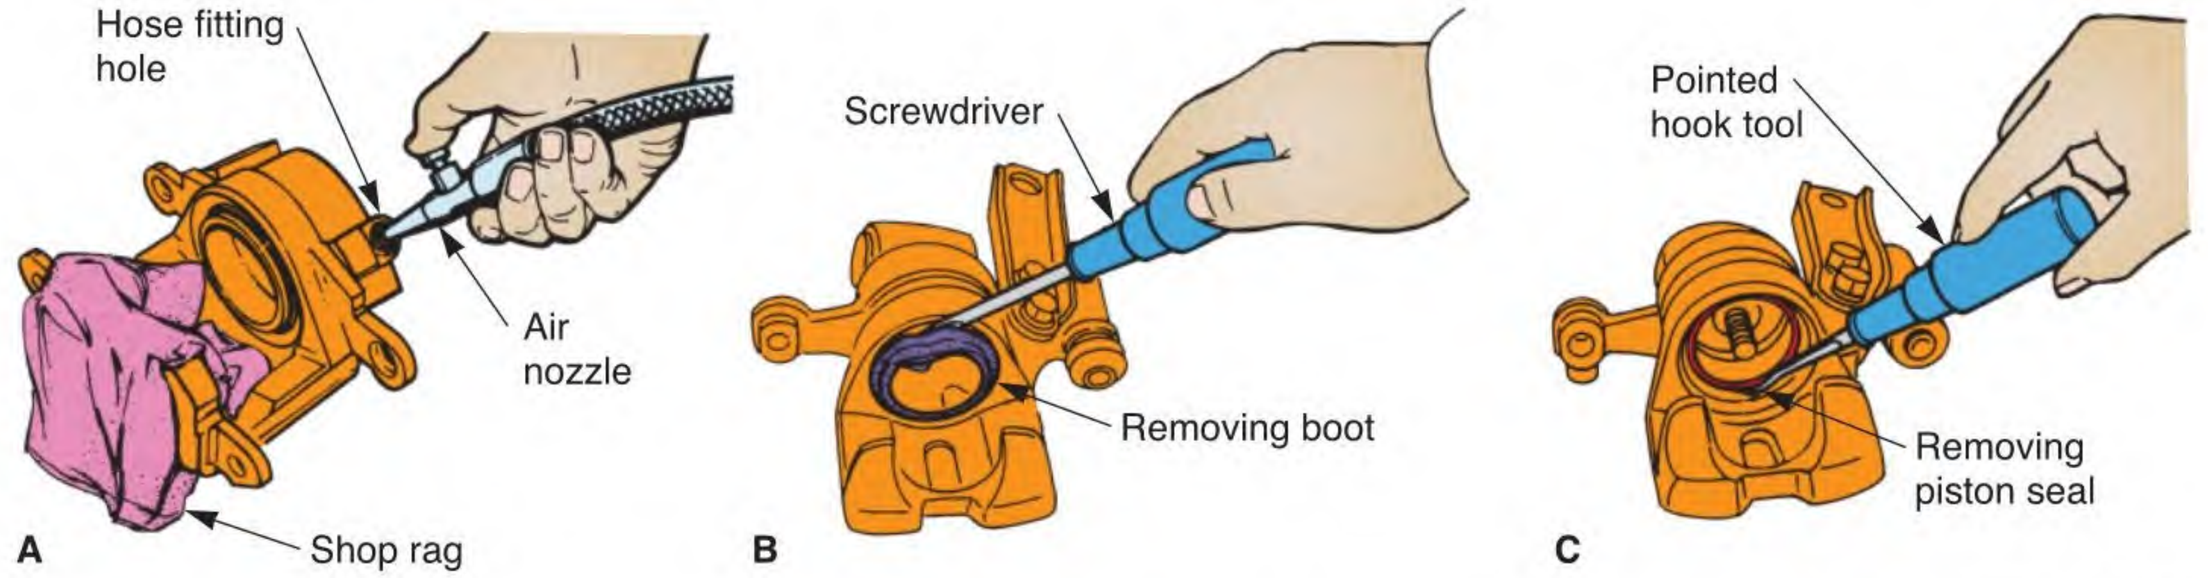
It is acceptable to service only the front or rear brakes. However, never service only the right or left brake assemblies. This could cause dangerous brake pull.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 81-12. Study basic steps for floating caliper pad service. A—Use a C-clamp or a large screwdriver to force the piston back into the caliper. This will open the caliper wide enough for the new, thicker pad linings. B—Use a six-point socket or an Allen socket to unscrew the bolts holding the caliper. C—Lift the caliper off the knuckle and support it on a piece of wire. Do not let the unit hang by the brake hose, or the hose could be damaged. D—Remove the old pads. Note the position of the anti-rattle clips. The clips can be reused if they are in good condition. New pads can be installed without caliper service if the vehicle has low mileage and if the boot and seals are in good condition.

Rebuilding a Caliper Assembly

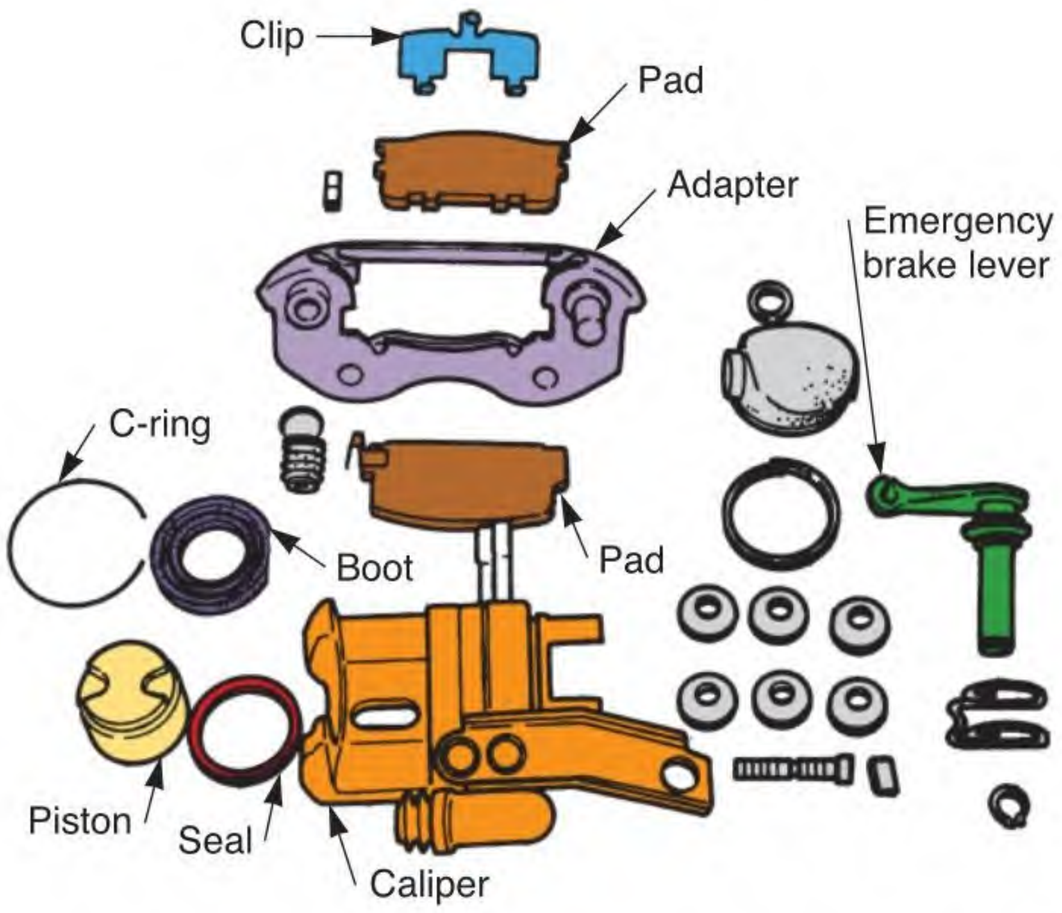


When a caliper piston is frozen, leaking, or has extremely high mileage, it must be rebuilt or replaced. Remove the caliper from the vehicle and take it to a clean work area.

To remove the piston from the caliper, apply just enough air pressure in the hose fitting hole to push the piston out of its cylinder, **Figure 81-13A**. Some automakers recommend using brake system hydraulic pressure to force the piston out of the caliper.

Warning

Keep your fingers out of the way when using compressed air to remove a caliper piston. A stuck piston could fly out with tremendous force. Serious hand injuries could result.



After piston removal, pry the old dust boot and the seal out of the caliper, **Figures 81-13B** and **81-13C**. Keep all parts organized on your workbench. Do not mix up right and left or front and rear parts. See **Figure 81-14**.

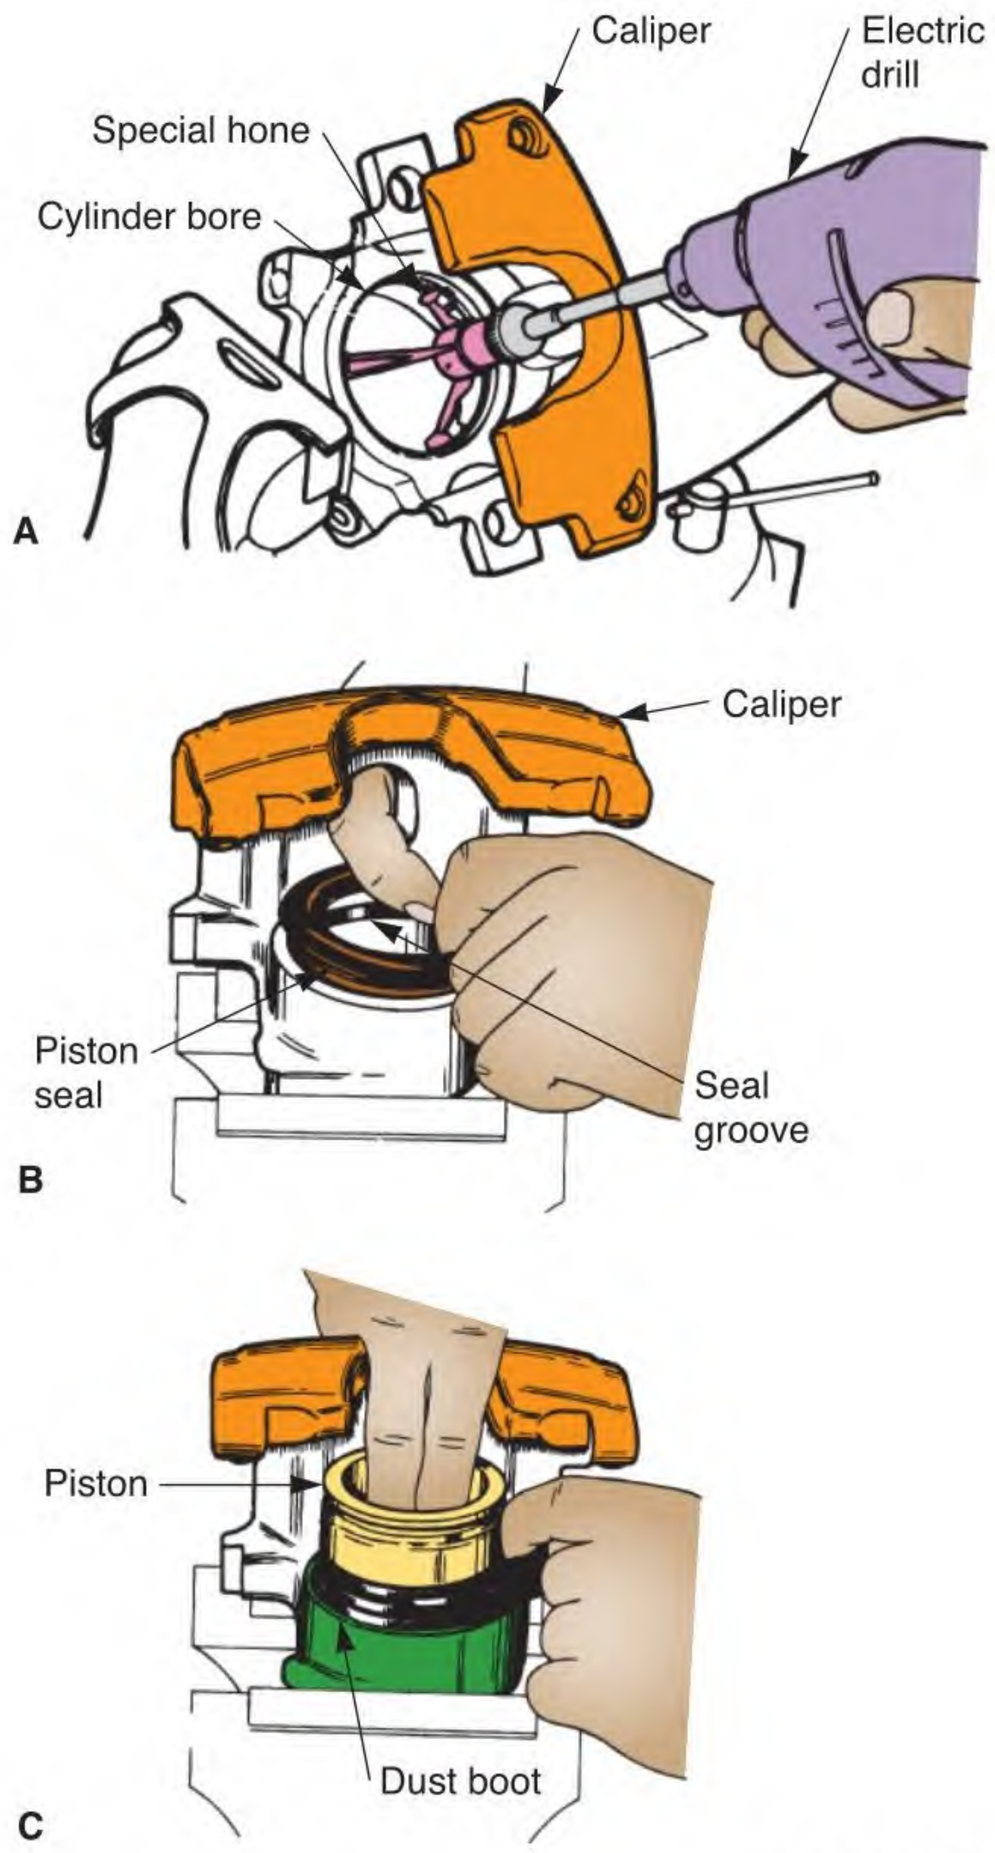
Goodheart-Willcox Publisher

Figure 81-13. Note the fundamental steps for caliper disassembly. A—Use air pressure or brake system pressure to push the piston out of the caliper. Place a thick rag or a block of wood in the caliper and keep your hands out of the way. B—Use a screwdriver or a similar tool to pry the old boot out of the caliper. C—A pointed hook-type tool will make removal of the old seal easy. The seal is positioned inside the groove in the cylinder.

Copyright Goodheart-Willcox Co., Inc.

Subaru

Figure 81-14. When servicing calipers, keep all parts organized on a workbench. Do not mix parts from the right and left sides of the caliper. Inspect all parts closely for signs of wear or damage.



Check the caliper cylinder wall for wear, scoring, or pitting. Light surface imperfections can be cleaned up with a cylinder hone. See **Figure 81-15A**. Use brake fluid to lubricate the hone. If excessive honing is needed, replace the caliper.

Also, check the caliper piston for wear or damage. Install a new piston if you find any problems. The piston and the cylinder are critical and must be in perfect condition.

Clean all the caliper parts with an approved cleaner. Wipe the parts clean with a clean shop rag. Then, coat them with brake fluid.

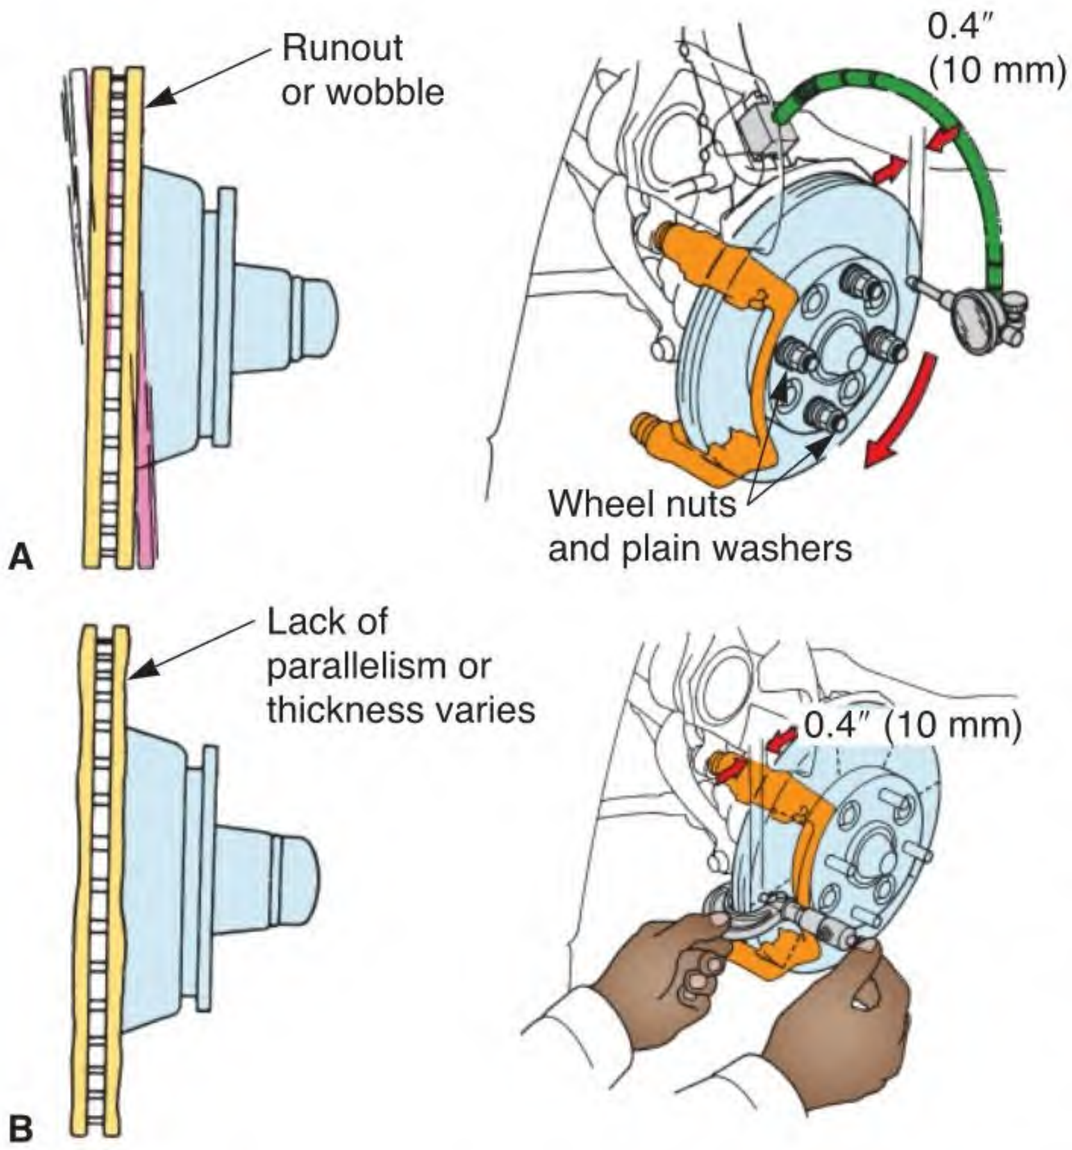
Assemble the caliper in the reverse order of disassembly. Typically, work the new seal into the cylinder bore groove with your fingers, **Figure 81-15B**.

Then, install the new boot in its groove. Coat the piston with more brake fluid. Spread the boot with your fingers and slide the piston into the cylinder, **Figure 81-15C**.

Chrysler and Bendix

Figure 81-15. Proper honing and reassembling are critical to a caliper rebuild. A— Electric drill spins a special hone inside the caliper cylinder. This removes minor surface flaws. B—Fit the new seal and boot into position. The seal must be down in its groove. Sometimes, it is easier to install the boot after installing the piston. C—Slide the piston into the cylinder squarely. Make sure the seal does not come out of its groove. Fit the boot into the groove on the outside of the piston.

Brake Disc (Rotor) Service



When servicing a disc brake system, it is important to check the condition of the brake disc. Automakers provide specifications for maximum disc runout (wobble) and minimum disc thickness. Also, the brake disc must not be scored, cracked, or heat checked.

Brake Disc Measurements

Brake disc runout is the amount of side-to-side movement measured near the outer edge of the disc's friction surface. A dial indicator is used to measure brake disc runout. See **Figure 81-16A**.

Compare your indicator reading to factory specifications. Typically, runout should not exceed 0.004″

Copyright Goodheart-Willcox Co., Inc.

EIS and Honda

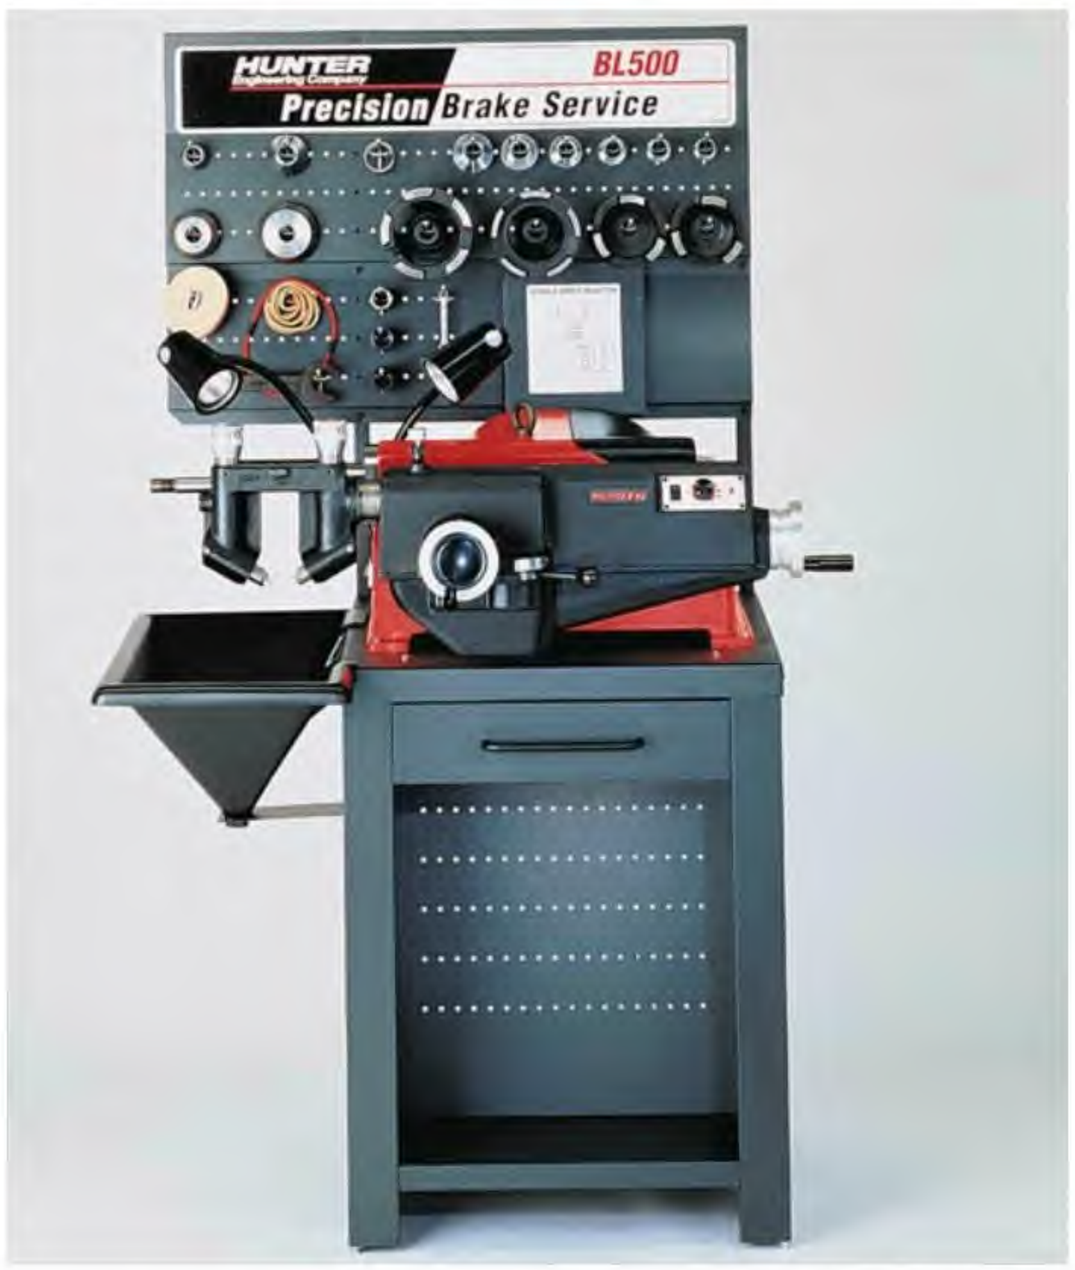
Figure 81-16. Checking for rotor runout and thickness variations is important. A—Mount a dial indicator as shown to measure disc runout, or wobble. Rotate the disc by hand and read the indicator. If runout is greater than specifications, the rotor should be turned or replaced. B—An outside micrometer can be used to detect any thickness variations. Take thickness measurements at several places around the disc. If readings are not the same, or if they are not within specifications, turn or replace the disc.

(0.10 mm). If runout is beyond specifications, turn (machine) the disc on a brake lathe to true its friction surfaces.

Brake disc thickness is measured across the two friction surfaces in several locations. Variation in disc thickness indicates wear.

To measure disc thickness, use an outside micrometer. Measure in several places around the disc. Compare your measurements to specifications, as in **Figure 81-16B**.

Minimum disc thickness will sometimes be printed on the side of the brake disc. If it is not, refer to a manual or brake specification chart. If brake disc thickness is under specifications, replace the brake disc.



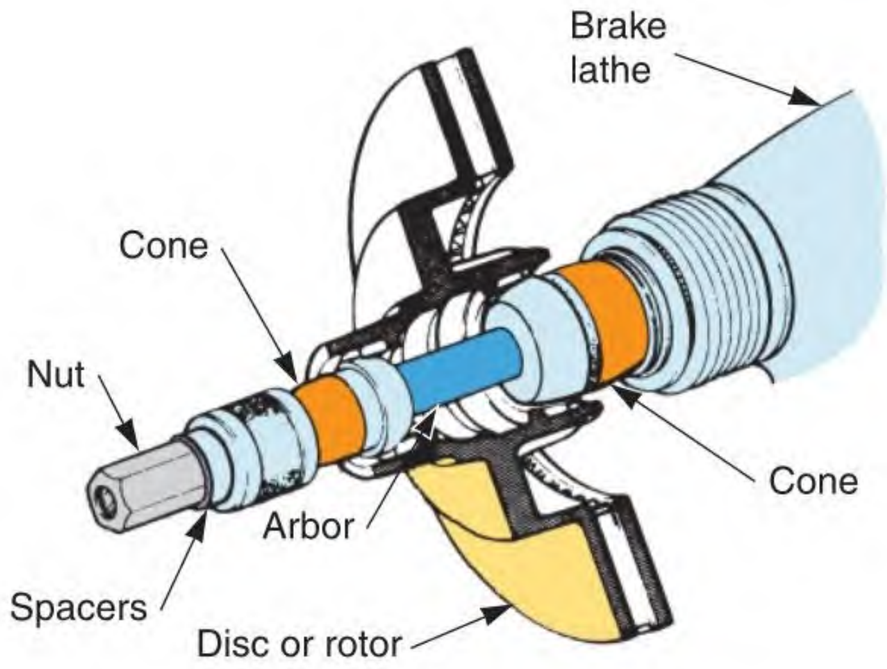
Tech Tip

A thin brake disc cannot dissipate heat properly and may warp or fail in service. A warped brake disc can cause severe vibration upon braking. Complete failure of the brake disc may severely damage other parts.

Resurfacing a Brake Disc

Brake disc resurfacing refers to machining a disc's friction surfaces on a brake lathe, **Figure 81-17**. Disc resurfacing is needed to correct runout, thickness variation, or scoring.

When a brake disc is in good condition, most manufacturers do not recommend resurfacing. Only machine a disc when it is absolutely necessary.



Hunter Engineering

Figure 81-17. Always read the operating manual before trying to use a brake lathe. Note the controls.

Copyright Goodheart-Willcox Co., Inc.

Warning

Do not attempt to operate a brake lathe without first obtaining proper training. The machine could be damaged or you could be injured by incorrect operating procedures. Look at **Figure 81-18**.

EIS

Figure 81-19. Special cones are used to mount the rotor on a brake lathe. The cones must contact the bearing races. Spacers and a nut then lock the assembly on the arbor.

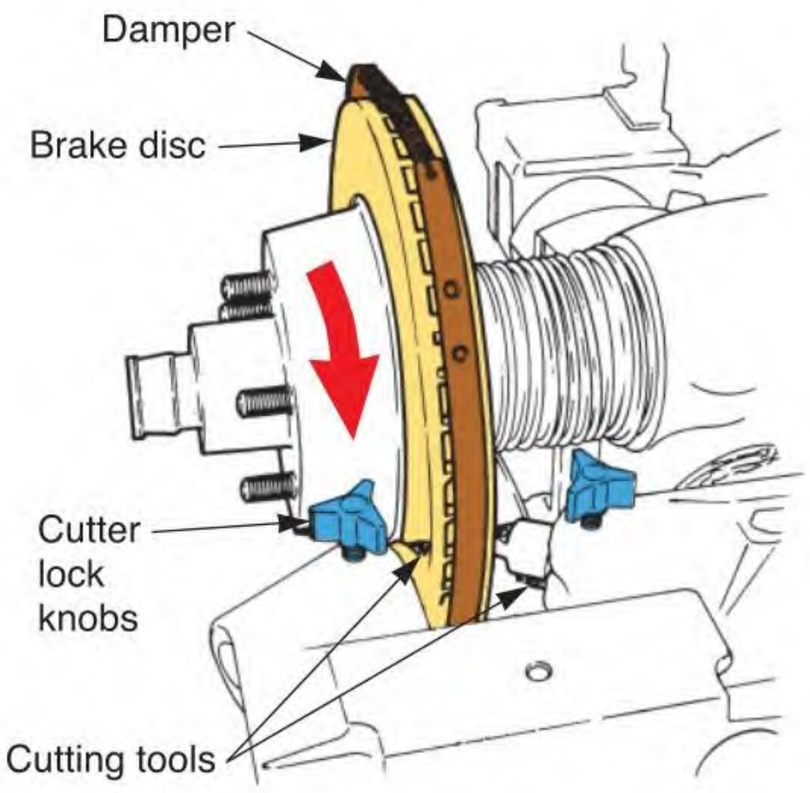
Service Procedure

To resurface a brake disc:

1. Mount the brake disc on the brake lathe. Use the appropriate spacers and cones to position the disc true on the machine's arbor. Follow the directions provided with the brake lathe. See **Figure 81-19**.
2. Tighten the large shaft nut on the machine so the brake disc is held firmly on the arbor. The nut must clamp the cones and spacers tightly against the bearing races.
3. Wrap a ***vibration damper*** (spring or rubber damper) around the disc to prevent high-frequency vibration and squeal, **Figure 81-20**.
4. While wearing eye protection, start the machine and adjust the cutting tools until they just contact the friction surfaces on the disc. Adjust the cutting tools very slowly so they barely touch the brake disc surface.
5. With the machine feeds and controls set properly, engage the auto feed mechanism to machine both smooth surfaces on the disc. Remove only enough metal to true the disc.

Tech Tip

Minimizing the depth of cut and feed speed will produce the longest lasting, smoothest finish on the surface of the brake disc. Overcutting and cutting too quickly is a common mistake that affects repair longevity.



6. Without touching the machined surfaces with your fingers, remove the disc from the lathe.
7. Double-check disc thickness and install the disc on the vehicle.

Ammco

Figure 81-18. This brake lathe has a large guard, or cover, that should be closed during operation. It protects you and others in the shop from flying debris if something goes wrong.

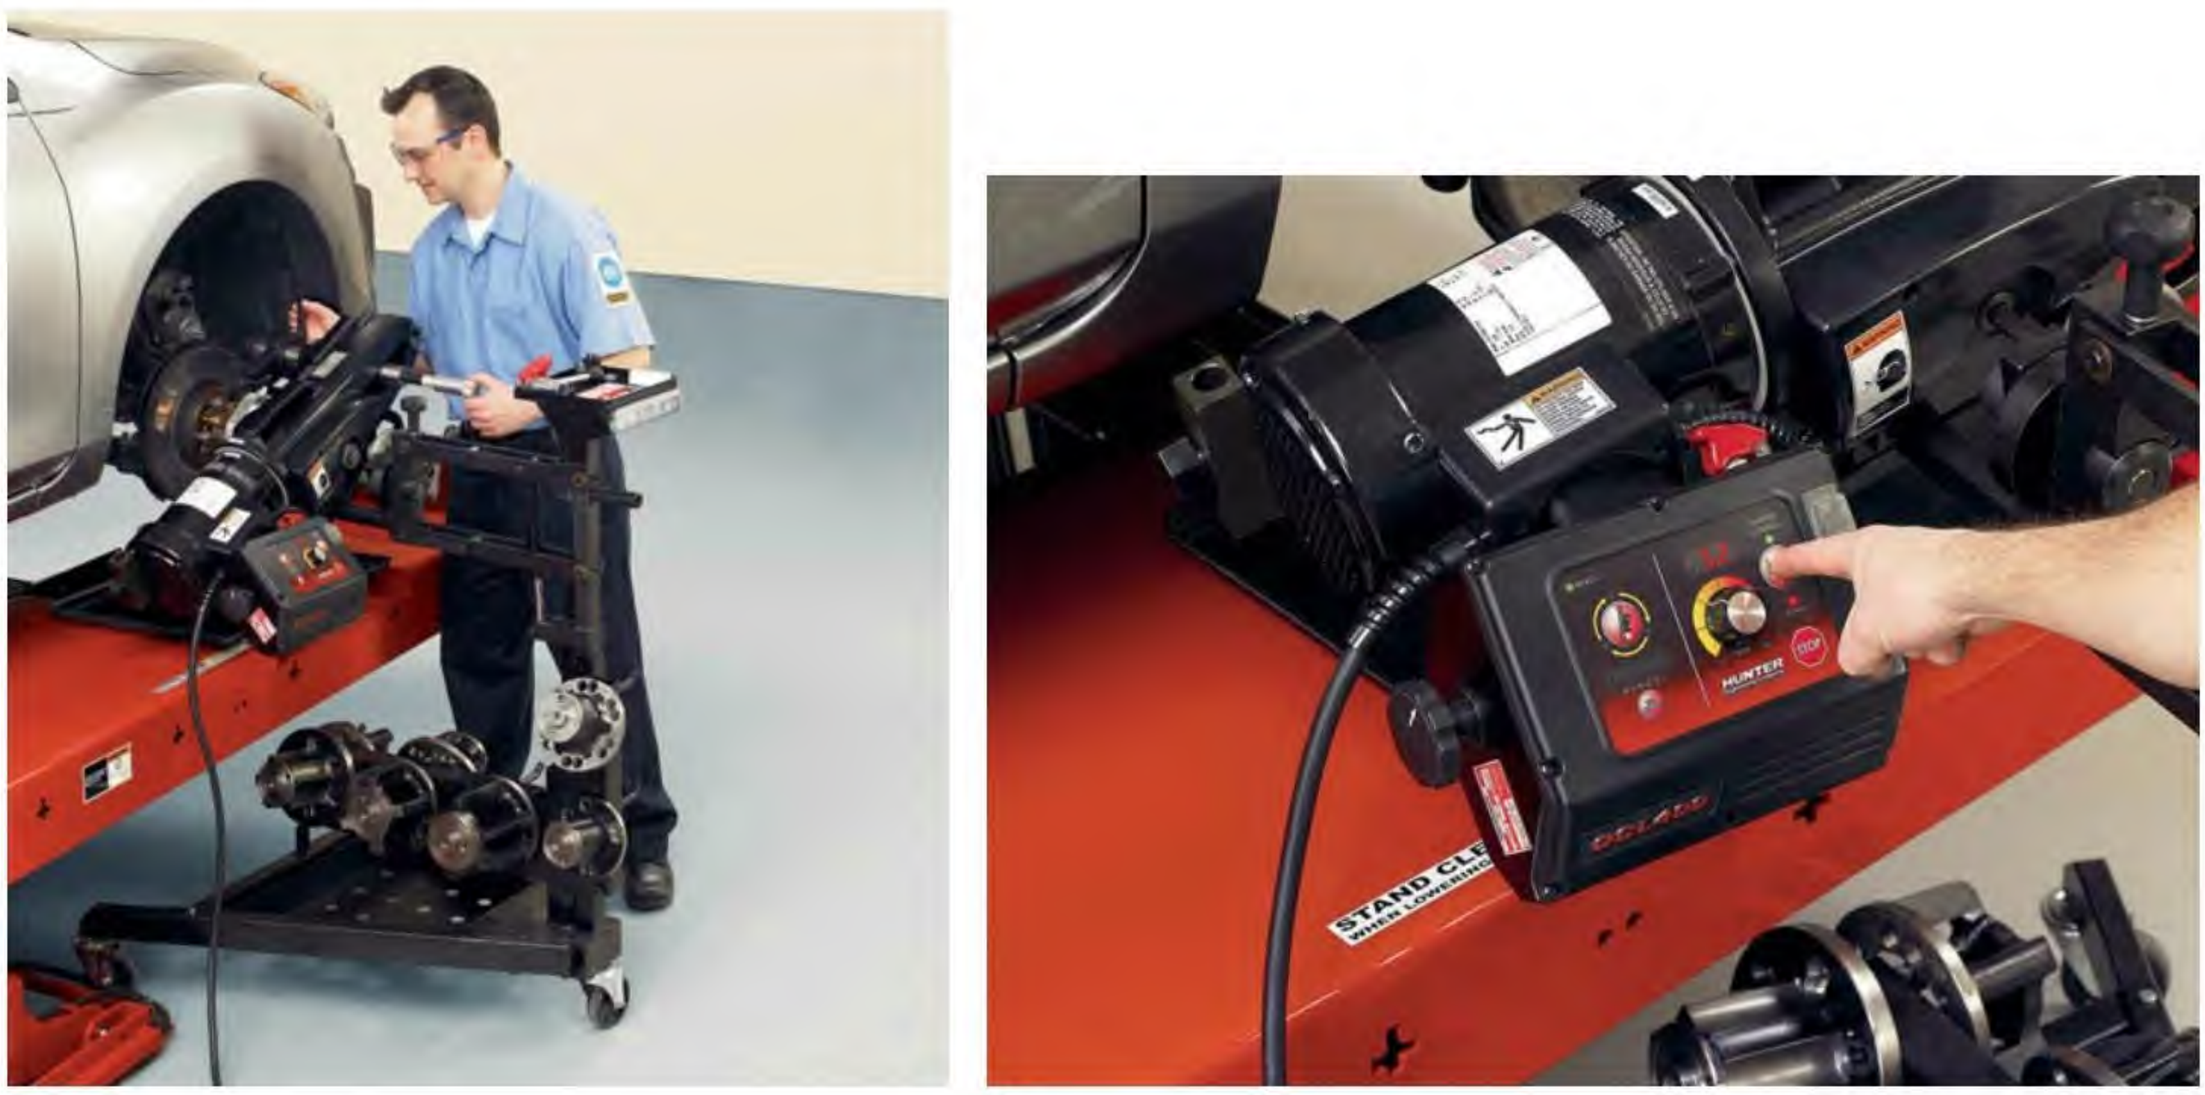
Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 81-20. After installing a damper to prevent vibration, small cutters are fed into the rotor a prescribed depth. Then, the controls are set so the cutters advance over the rotor's surface automatically.

On-Car Brake Lathes

Some European and Asian front-wheel-drive vehicles have brake discs that are difficult to remove. With these vehicles, an on-car disc lathe (grinder) is a time-saver because you do not have to remove the disc to machine it. The lathe mounts on the vehicle's steering knuckle. A large electric motor turns the disc during the machining process. See **Figure 81-21**.



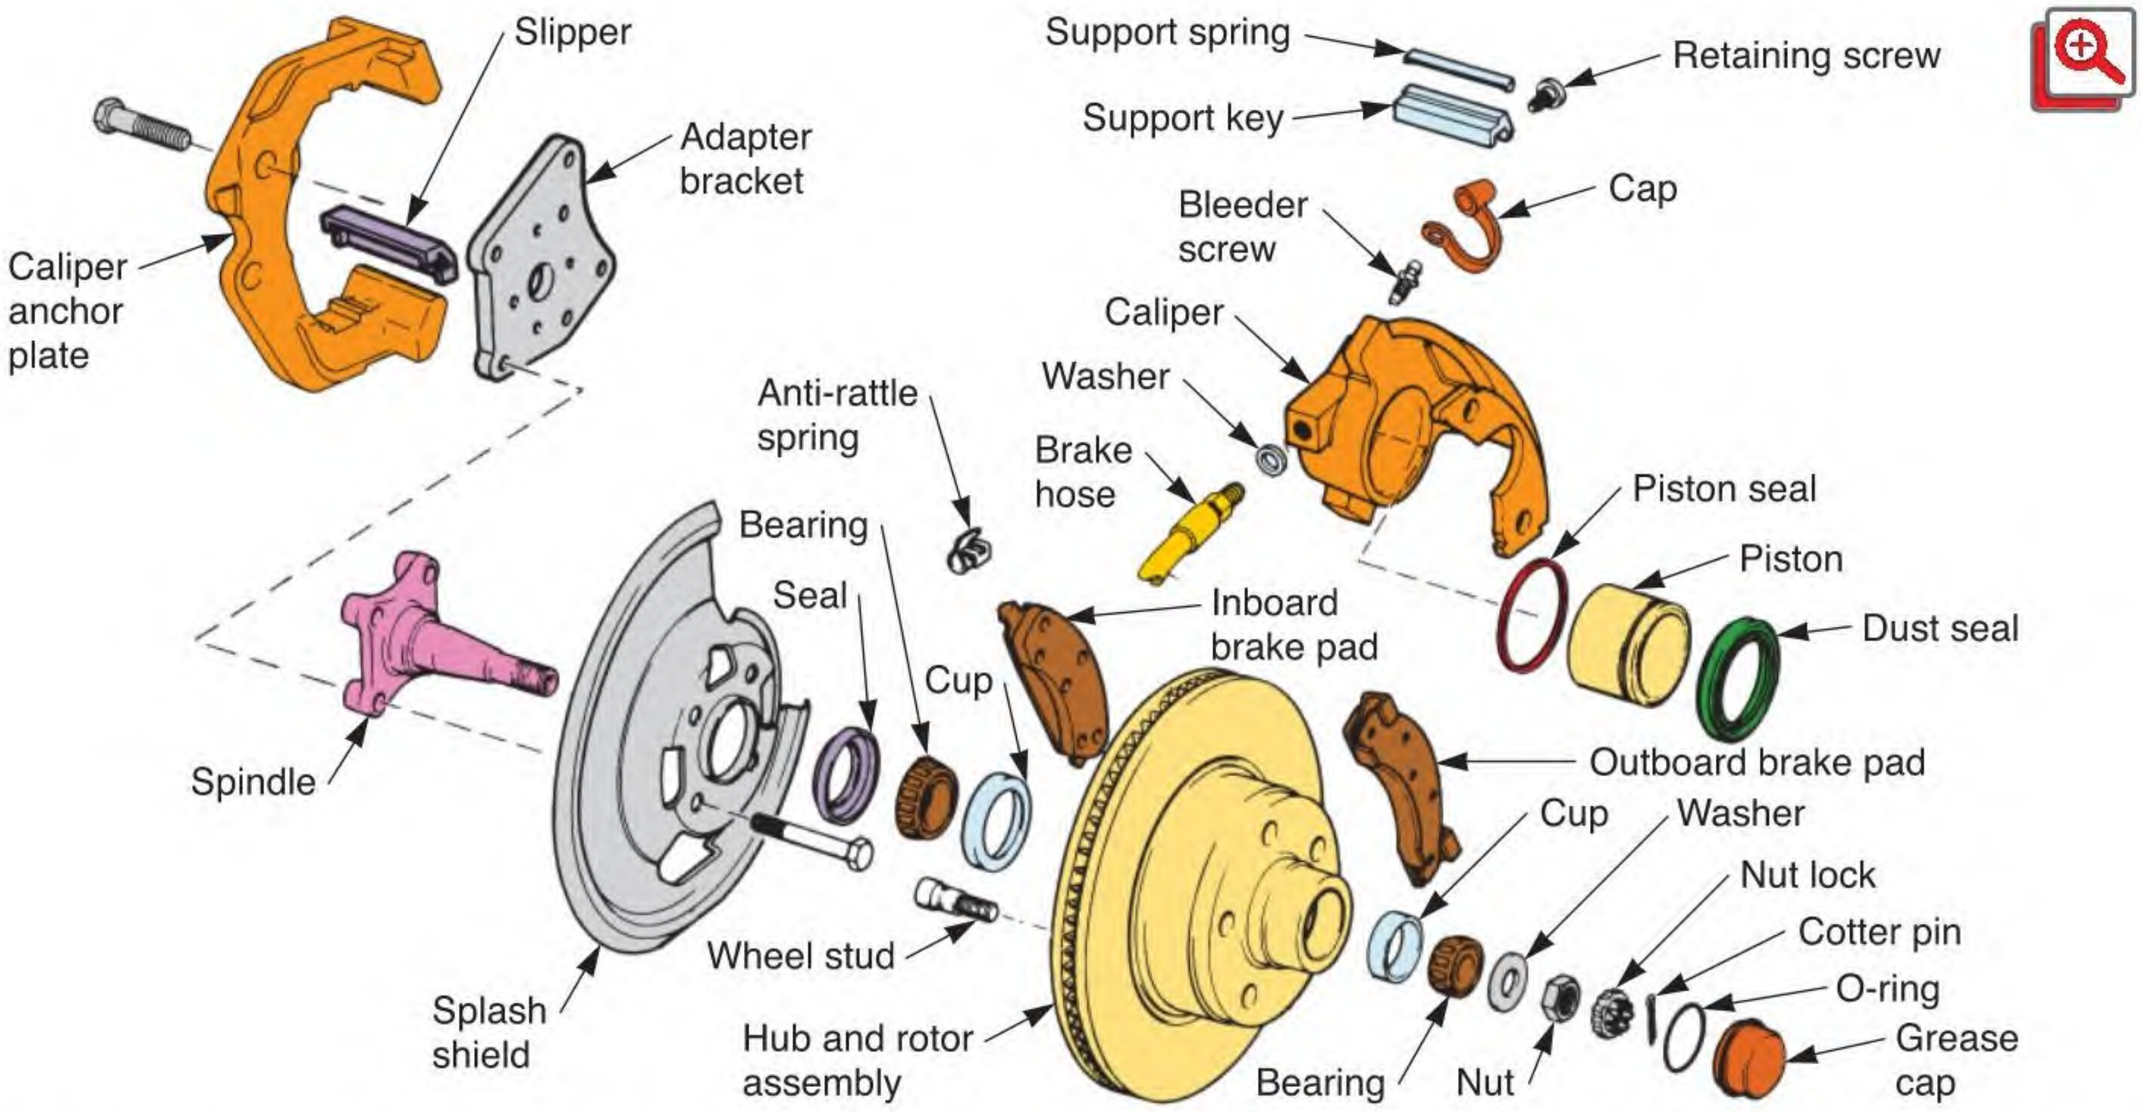
Disc Brake Reassembly

Reassemble the disc brake in the opposite order of disassembly, **Figure 81-22**.

After installing the brake disc, fit the caliper assembly into place. Make sure the new pads are properly installed. In some cases, high-temperature silicone is used on the backs of the pads to help prevent brake rattle and squeal.

If recommended, apply a small amount of grease to the caliper mounting bolt threads. This will ensure proper tightening and secure mounting of the caliper, **Figure 81-23**. Torque all caliper fasteners to specifications.

During assembly, keep your hands off the surface of the disc and the brake pad linings. Grease will burn and harden on the friction lining, causing brake squeak. Refer to **Figure 81-24**.



A B

Hunter Engineering

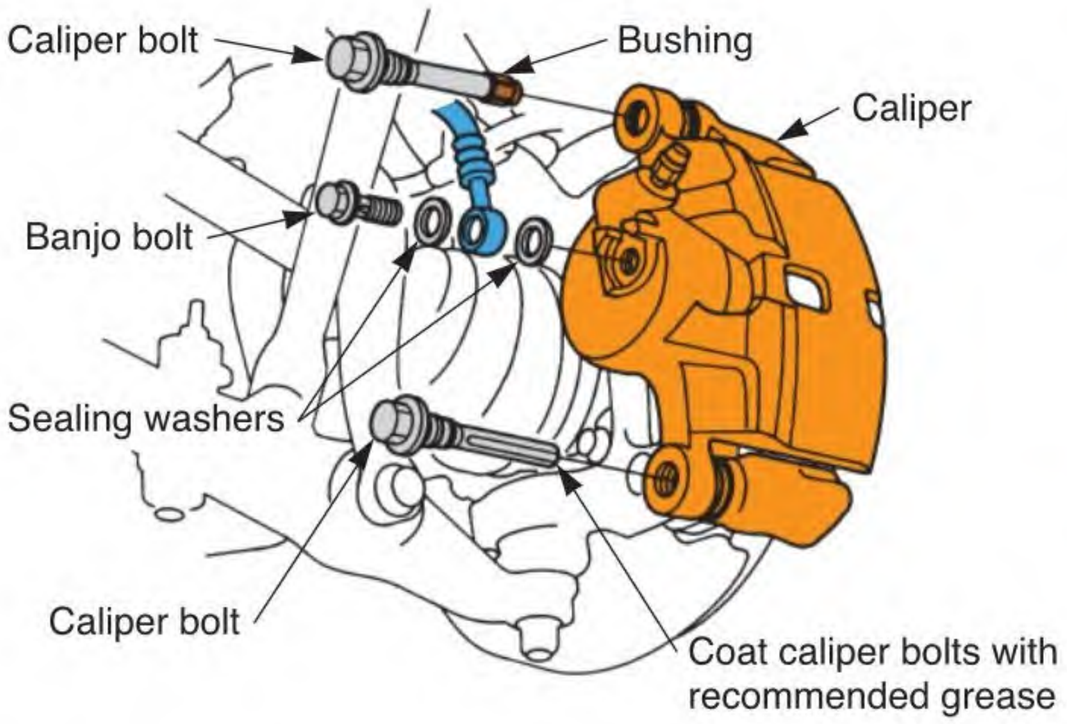


Figure 81-21. An on-car brake lathe is handy when rotors are difficult to remove from a vehicle. A—Mount the hub adapter on the vehicle. Move lathe into position and adjust its height so that the adapter engages the drive head on the machine squarely. Then adjust cutters up against the disc for machining. B—The on-car lathe assembly has controls for feeding cutters into the disc surface. Understand all of the control functions before operating the machine.

Chrysler

Figure 81-22. Study parts of a disassembled disc brake assembly. Study how the parts fit together.

Honda

Figure 81-23. When reinstalling a caliper, lubricate the bolt threads. Make sure the special washers are in place on the brake hose, if used.

Tech Tip

Some disc brake rotors have their fins arranged to pull air through the inside of the rotor in only one direction. The spinning action of the rotor aids cooling. With these designs, the rotors are different on the right and left sides of the vehicle. If you accidentally reverse sides or purchase a rotor for the wrong side, rotor overheating and damage can result. Not enough air will be pulled through the rotor to prevent heat-related warpage during hard braking.

Drum Brake Service

Although specific procedures vary, you should understand the most important methods for servicing a drum brake. Service is needed anytime your diagnosis finds faulty drum brake components. A leaking wheel cylinder, worn or contaminated linings, scored drum, or other troubles require immediate repairs.

Complete ***drum brake service*** typically involves:

- Removing parts from the backing plate.
- Cleaning and inspecting the parts.
- Replacing the brake shoes.
- Replacing or rebuilding the wheel cylinders.
- Turning (resurfacing) the brake drums.
- Lubricating and reassembling the brake parts.
- Preadjusting, bleeding, and testing the brakes.

Copyright Goodheart-Willcox Co., Inc.

Volvo

Figure 81-24. Rotor and lining surfaces should be perfectly clean after repairs are complete. If you accidentally get greasy fingerprints on the rotor, wipe off the surfaces with an approved solvent.

Figure 81-25 shows some special brake service tools.

Drum Brake Disassembly

To disassemble drum brakes, remove the tire-and-wheel assemblies and the brake drums, **Figure 81-26**.

If the drum is rusted to the axle flange, light taps with a hammer may be needed. Hammer on the outside edge of the drum. Do not hammer on the inner lip of the drum, or it can break. You may also need to back off the adjuster if the drum is worn. This is shown in **Figure 81-27**.

Use a brake spring tool to remove the upper shoe return springs, **Figure 81-28A**. Organize the springs so that they can be installed in the same location. The primary and secondary springs are usually a different color and tension. Use a hold-down spring tool to remove the hold-down springs, **Figure 81-28B**.

Lift the brake shoes off the backing plate. Remove the automatic adjuster mechanism. See **Figure 81-29**.

Before disassembling the wheel cylinder, clean the backing plate. Wipe off the plate with a shop rag. If the backing plate is coated with brake fluid or axle lubricant, wash the plate with an approved cleaner.

Servicing Wheel Cylinders

Pull back the wheel cylinder boots. The wheel cylinder should be rebuilt or replaced if it shows signs of leakage or sticking. In fact, many shops service the wheel cylinders anytime the linings are replaced, **Figure 81-29**.

To service a wheel cylinder, remove the boots, the pistons, the cups, and the spring. Usually, the wheel cylinder can be serviced while bolted to the backing plate. Sometimes, however, the wheel cylinder must be removed before disassembly.

A ***wheel cylinder rebuild*** normally involves honing the cylinder and replacing the rubber cups and boots.

It is very important that the inside of the cylinder be in good condition. Cylinders that are deeply scratched, scored, or pitted must be replaced.

To hone a wheel cylinder, mount the small hone in an electric drill. Insert the hone in the cylinder. Turn on the drill while moving the hone back and forth in the cylinder. Keep the hone lubricated with brake fluid.

Warning

When honing a wheel cylinder, do not pull the hone out of the cylinder. The spinning hone could fly apart. Wear eye protection!

After honing, wash the wheel cylinder thoroughly with brake fluid or an approved cleaning solvent. Dry the cylinder with clean shop rags. Make sure the cylinder is clean and in perfect condition before reassembly. The slightest bit of grit or roughness could cause cup leakage.

Make sure the new wheel cylinder cups are the same size as the old ones. Cup size is normally printed on the face of the cup. Coat the parts with brake fluid and fit them into the cylinder.

Brake Drum Resurfacing

Brake drum resurfacing, also called ***turning***, involves machining the friction surface of the drum on a brake lathe. Look at **Figure 81-30**.

Copyright Goodheart-Willcox Co., Inc.

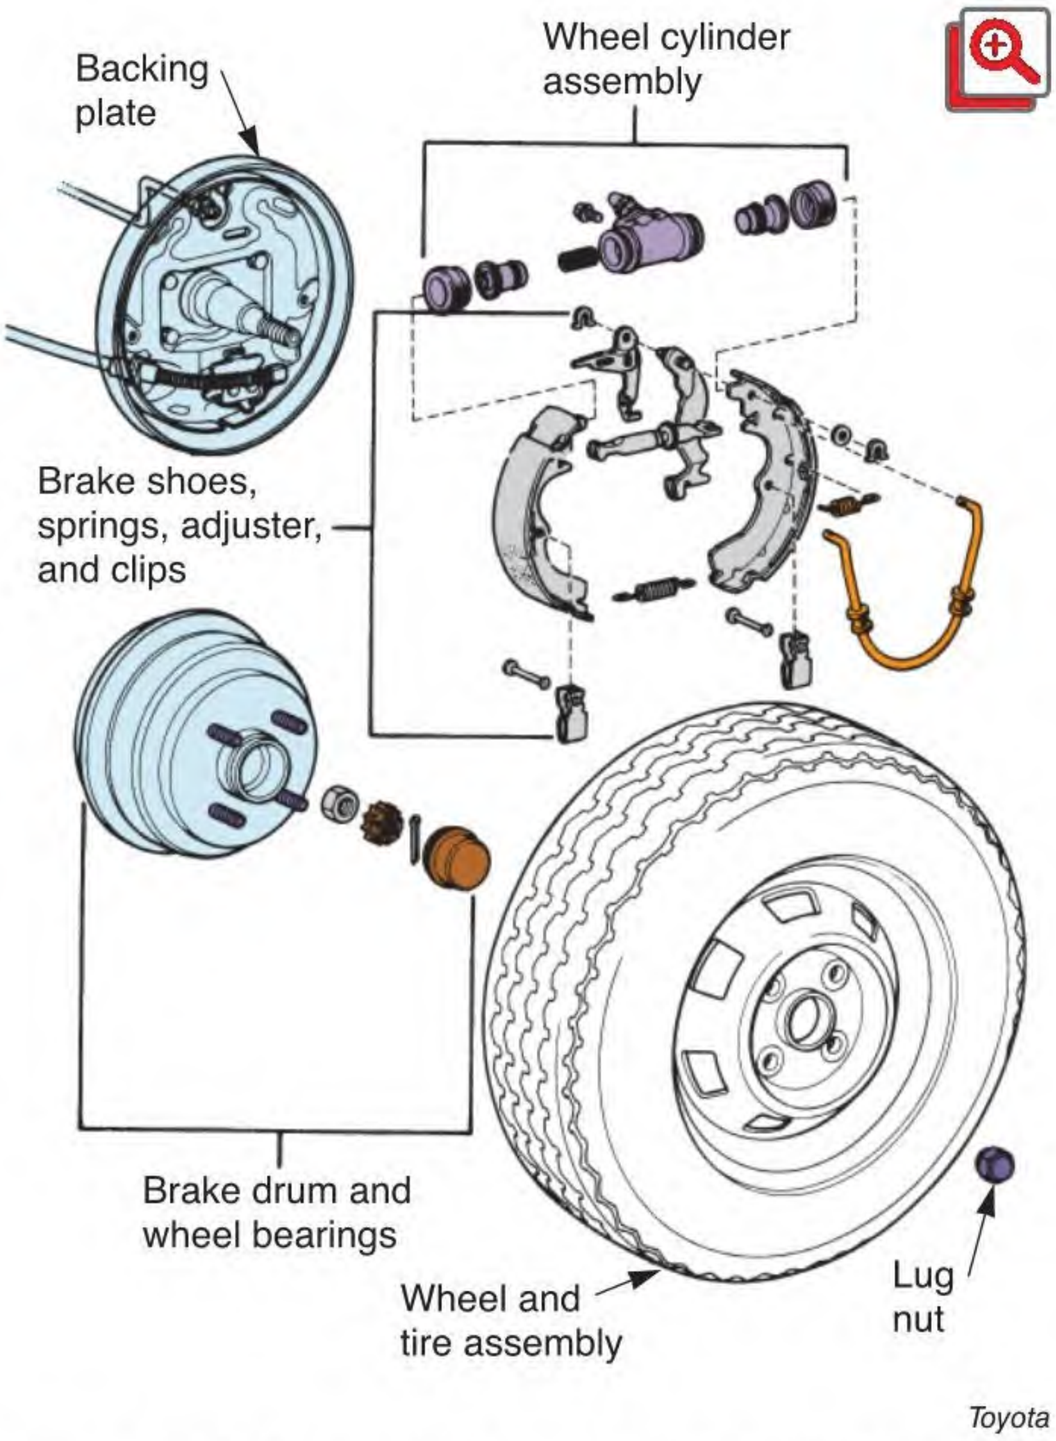
A

Snap-on Tool Corp.; Nilfisk

Figure 81-25. A—Special tools and equipment are available for servicing drum brakes. Small brake tools make the work fast and easy. B—A brake vacuum is used for cleaning off brake assemblies. It helps prevent you from breathing brake lining dust, which can contain asbestos—or a similar heat-resistant material—a possible cancer-causing agent.

Resurfacing is needed when the drum is scored, out-of-round, or worn unevenly. Some shops machine a drum anytime the brake linings are replaced. Other shops only resurface the drum when needed. Refer to auto manufacturer suggestions when in doubt.

To resurface a brake drum, mount the drum on the lathe. Follow the operating instructions for the particular lathe. Wrap a silencing band (rubber or spring strap) around the outside of the drum. The band will prevent vibration that could affect drum surface smoothness, **Figure 81-31**.



Wearing eye protection, feed the cutting tool against the inner surface of the drum. Adjust the depth of the cut to lathe specifications and activate the automatic feed.

When resurfacing a drum, remove as little material as possible. Resurfacing thins the metal around the friction surface. As a result, the drum is more prone to overheating and warping.

Machine the right- and left-hand drums to the same diameter. This will help ensure even, straight-line braking.

A conventional cutting tool will not remove metal from hardened areas of the brake drum. A high spot will remain on the friction surface, and brake vibration will result. ***Brake drum grinding*** is sometimes needed to remove this hardened metal and to true the friction surface. The grinder is mounted on the lathe in place of the cutter arm.

Copyright Goodheart-Willcox Co., Inc.

Toyota

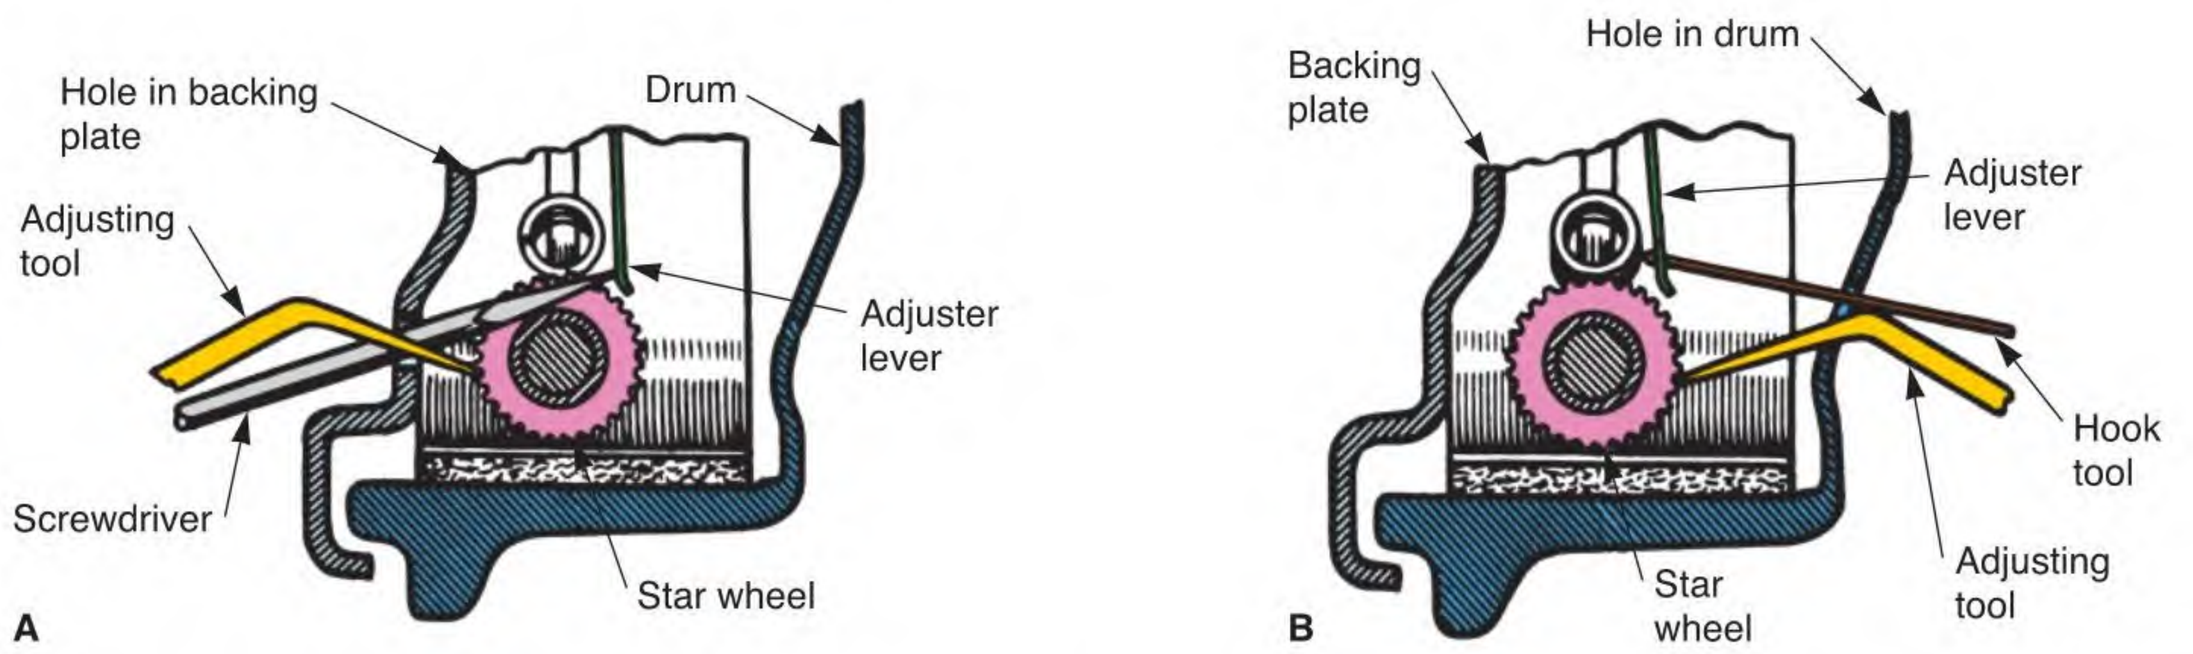
Figure 81-26. Disassembled drum brake assembly. Note the part relationships.

Measuring Brake Drum Diameter

Typically, a brake drum should not be more than 0.060″ (1.5 mm) oversize. Look at **Figures 81-32A** and **81-32B**. For example, a drum that is 9″ (229 mm) in diameter when new must not be over 9.060″ (230 mm) in diameter after resurfacing. If larger in diameter, the drum is dangerously thin.

To measure brake drum diameter, use a special brake drum micrometer. It will measure drum diameter quickly and accurately, **Figure 81-32C**.

Replace the drum if it is worn beyond specifications. Sometimes, maximum diameter is stamped on the side of the brake drum.

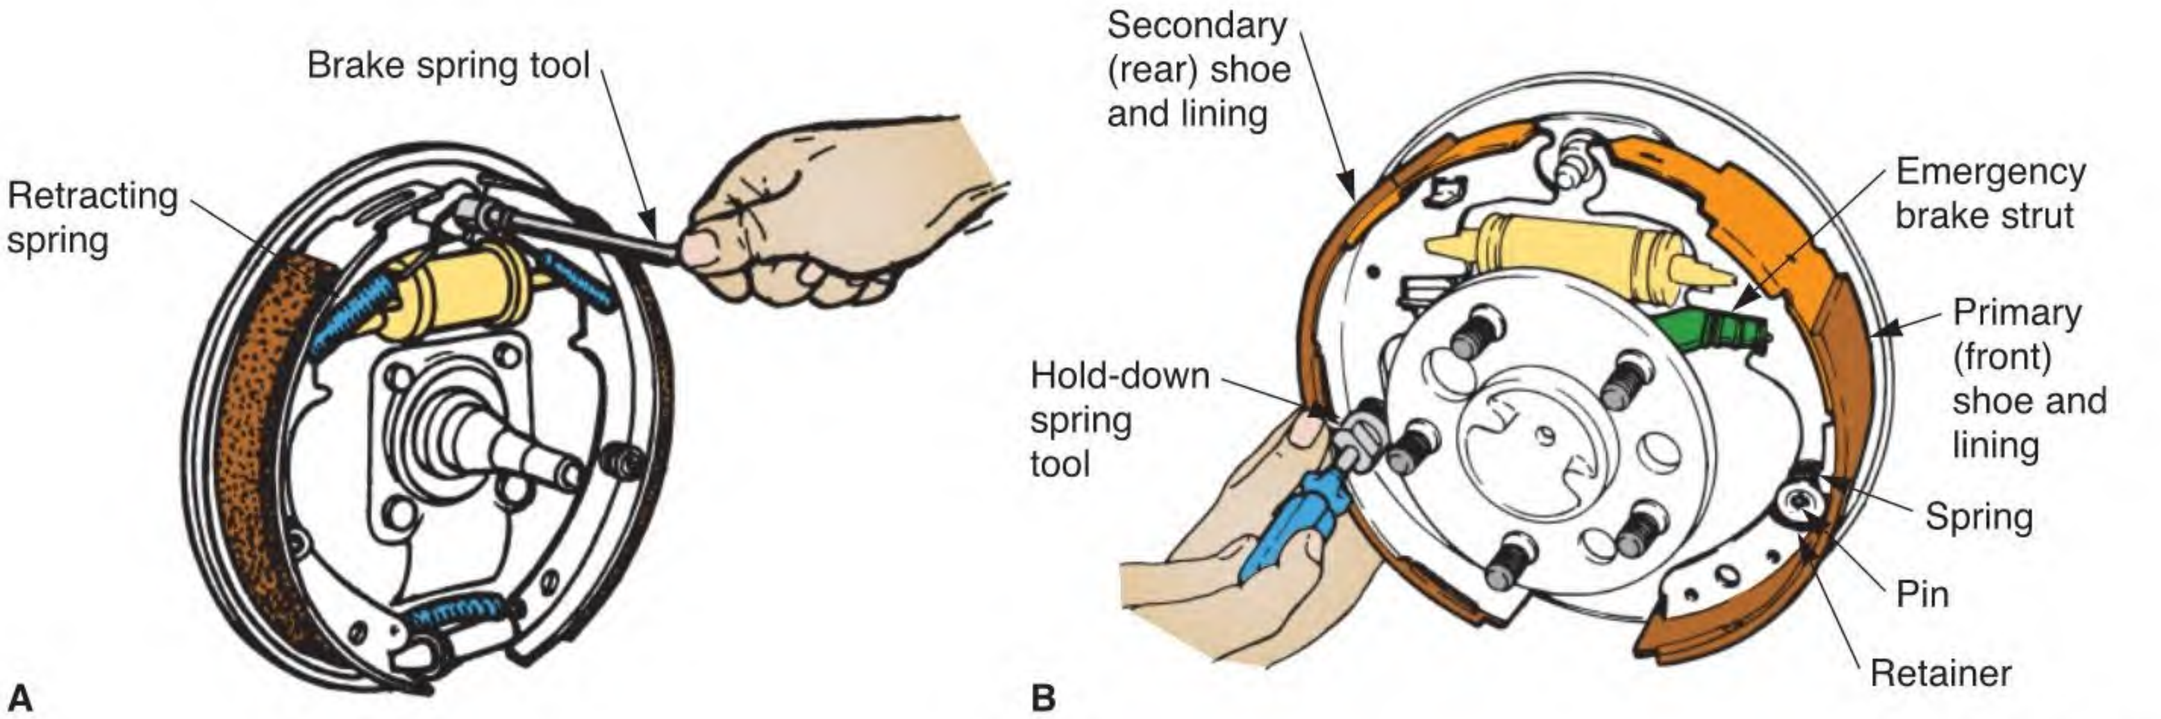


Drum Brake Reassembly

Before reassembling drum brakes, clean the wheel bearings and inspect them for wear or damage. Then, pack the bearings with grease and install new grease seals.

Lubricate the small pads or bumps on the backing plate. This will keep the shoes from squeaking. Avoid using too much lubricant, or the linings can become contaminated and ruined, **Figure 81-33**. Also, lubricate the threads on the star wheel screw, if there is one.

Before installing the new shoes, check their fit inside the brake drum. There should be a small clearance between the ends of the lining and the drums. The shoes should rock slightly when moved in the drum. If the centers of the linings are not touching the drum, the linings should be arced (ground).



When arcing brake shoe linings, follow the instructions provided by the equipment and vehicle manufacturer. Basically, you must grind the linings so that they are 0.35″ (0.89 mm) smaller in diameter than the drum. Without this clearance, the linings could chatter and vibrate when returned to service.

Bendix

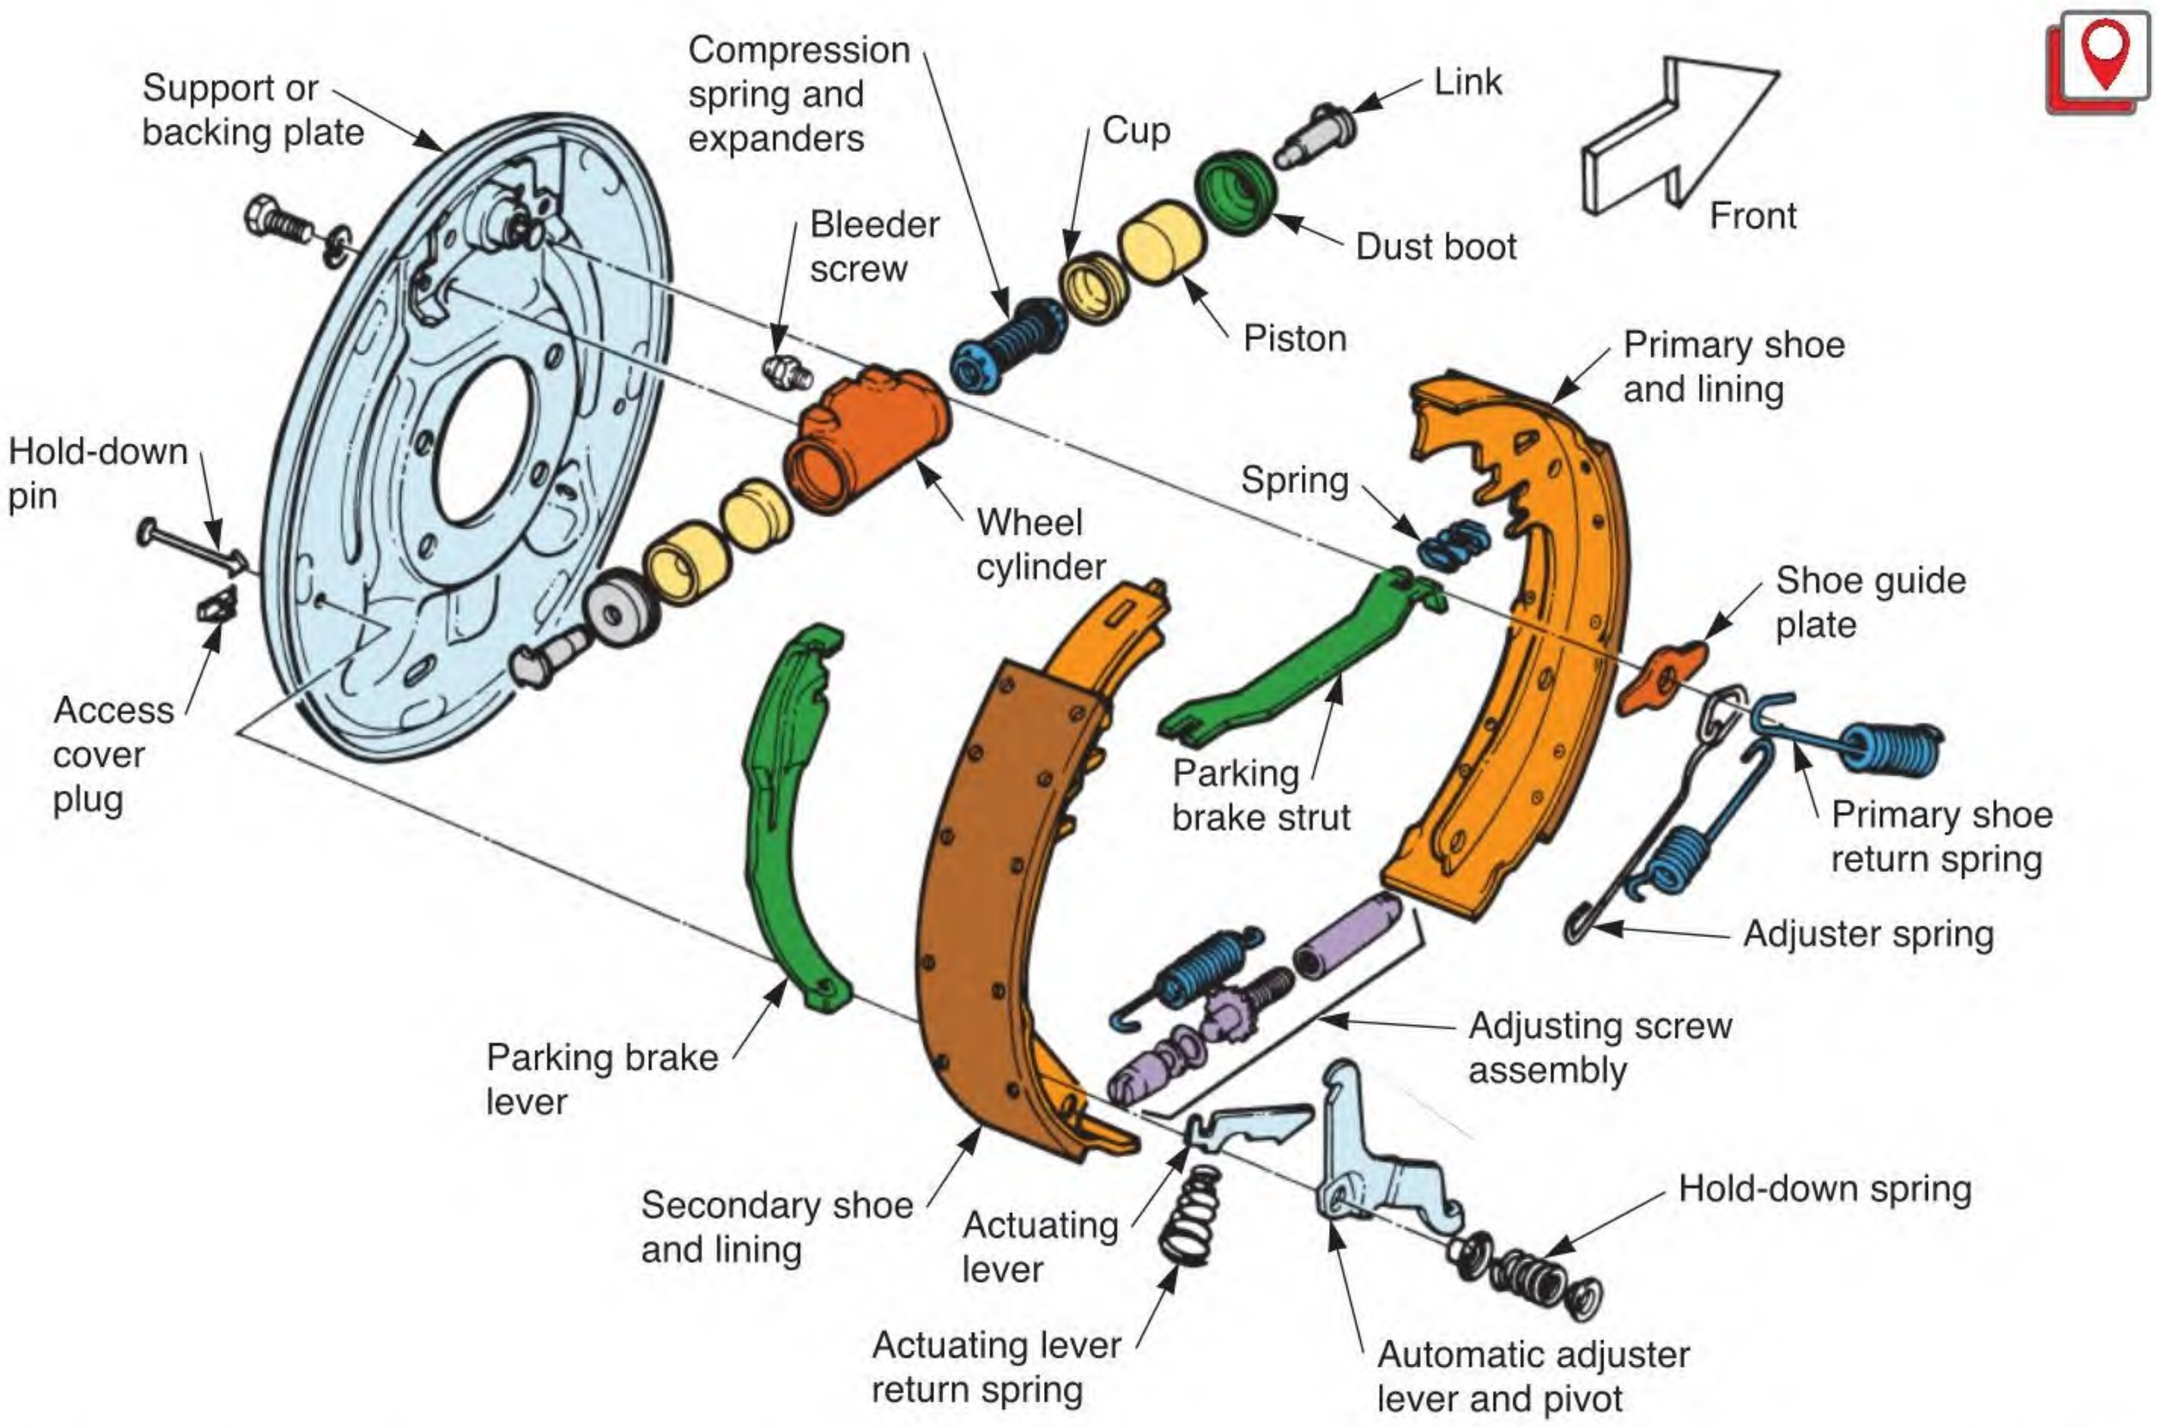


Figure 81-27. Backing off the star wheel will allow drum removal. A—When the access hole is in the backing plate, hold the lever and turn the star wheel as shown. B—Turning the star wheel when the access hole is in the drum.

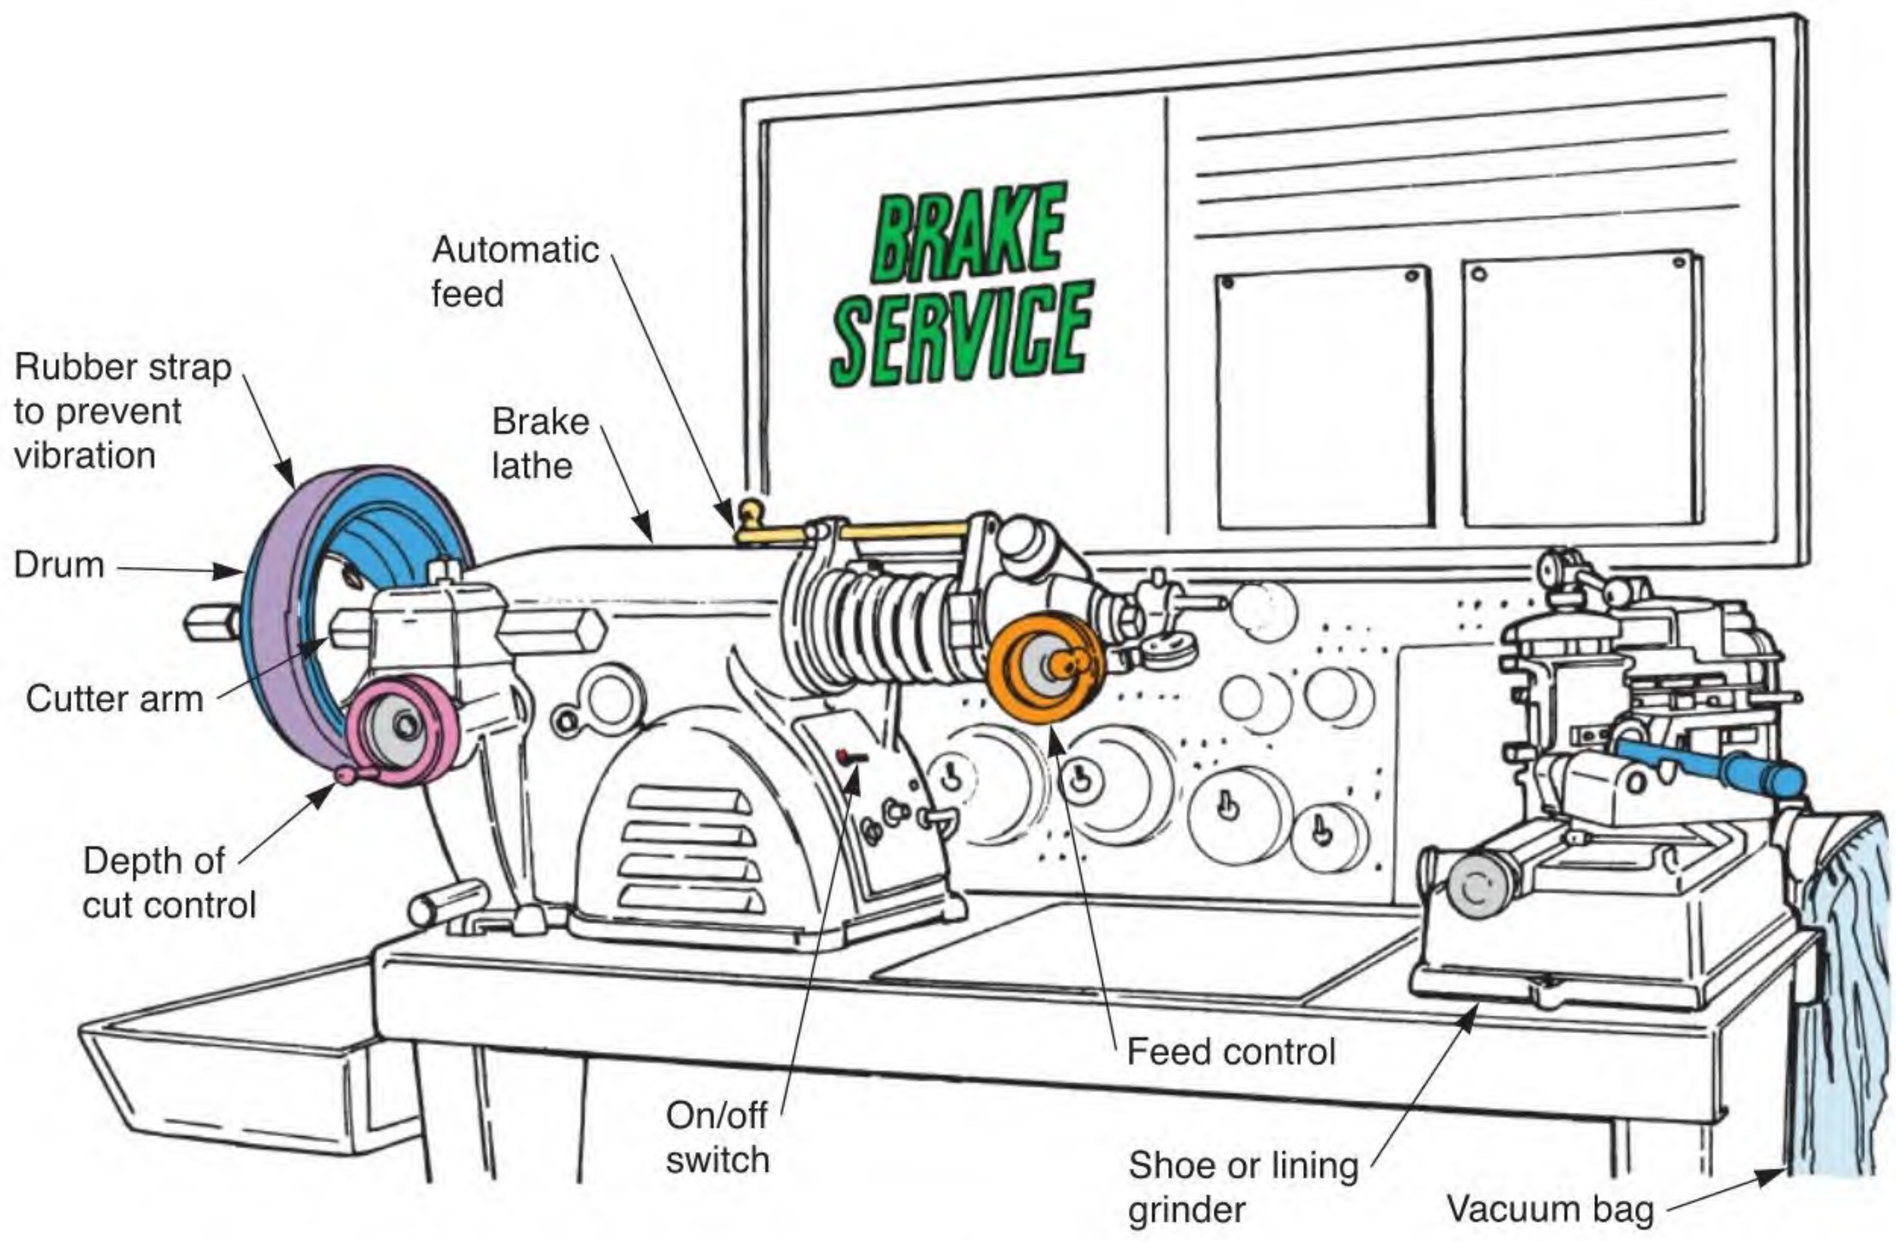
Goodheart-Willcox Publisher

Figure 81-30. When installing a brake drum on a lathe (similar to a rotor), you must use the correct cones, spacers and hubs. The cone is slid on the lathe shaft ahead of the drum and rests against the inner side of the drum. These parts will safely secure the drum to the lathe shaft.

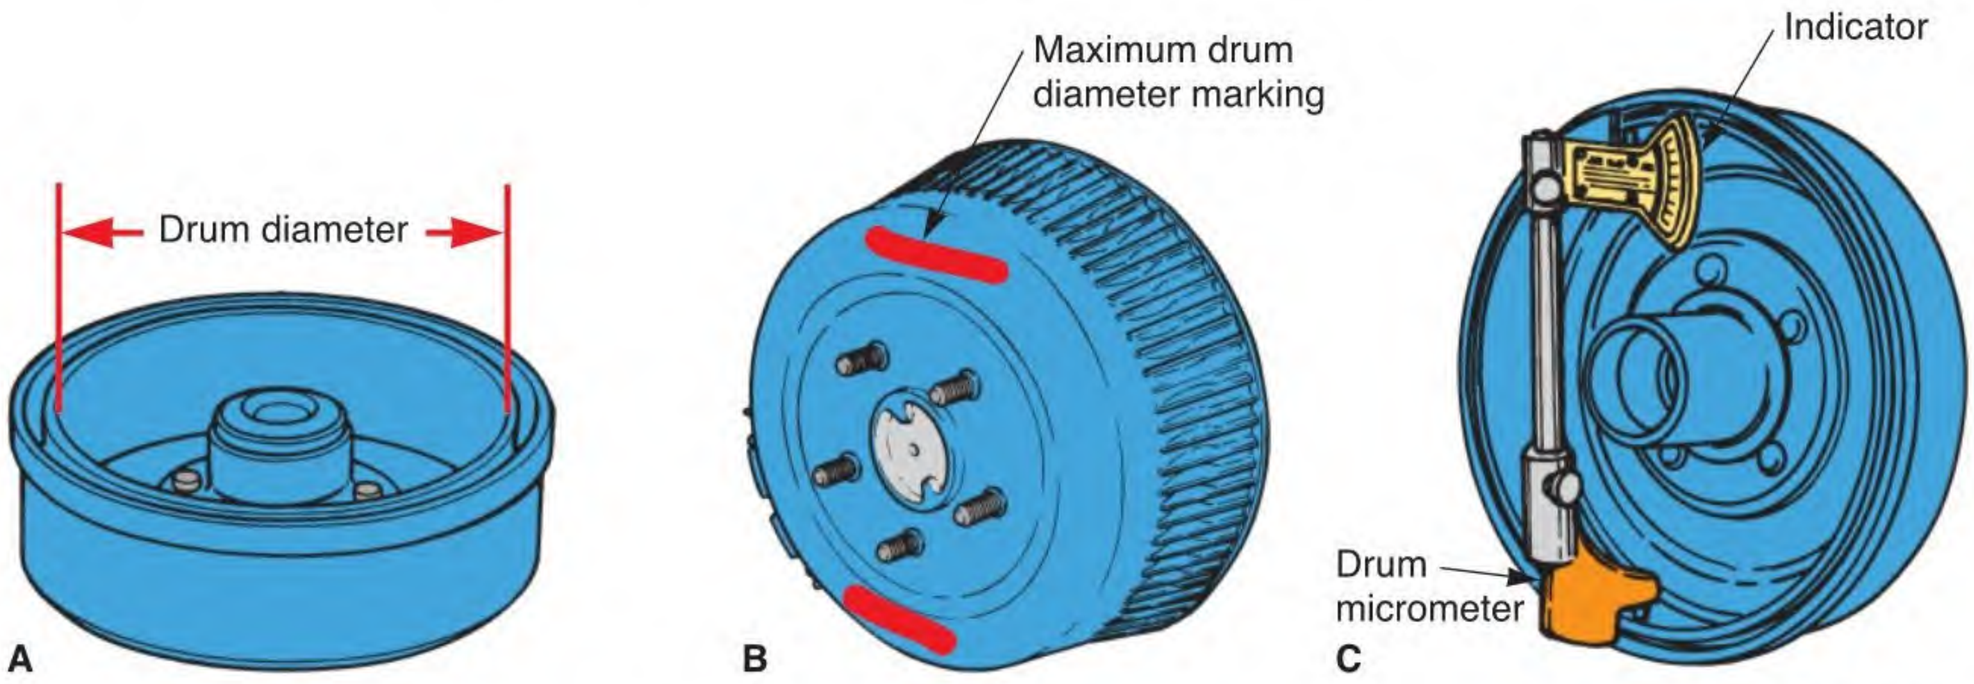


Warning

Make sure the vacuum system on the lining grinder is working properly. Remember that asbestos brake lining dust can cause cancer. Even dust from non-asbestos brake linings is unhealthy to breathe. At a minimum, wear a dust respirator mask when working on friction brakes.

Install the new shoes and the adjuster mechanism on the backing plate. Make sure all the parts are positioned correctly, **Figure 81-34**.

Ask yourself the following brake service questions:



- Are the wheel cylinders in perfect condition and assembled properly?
- Did I lubricate the backing plate and the star wheel?
- Is the primary (smaller) lining facing the front of the vehicle and the secondary (larger) lining facing the rear of the vehicle?

EIS

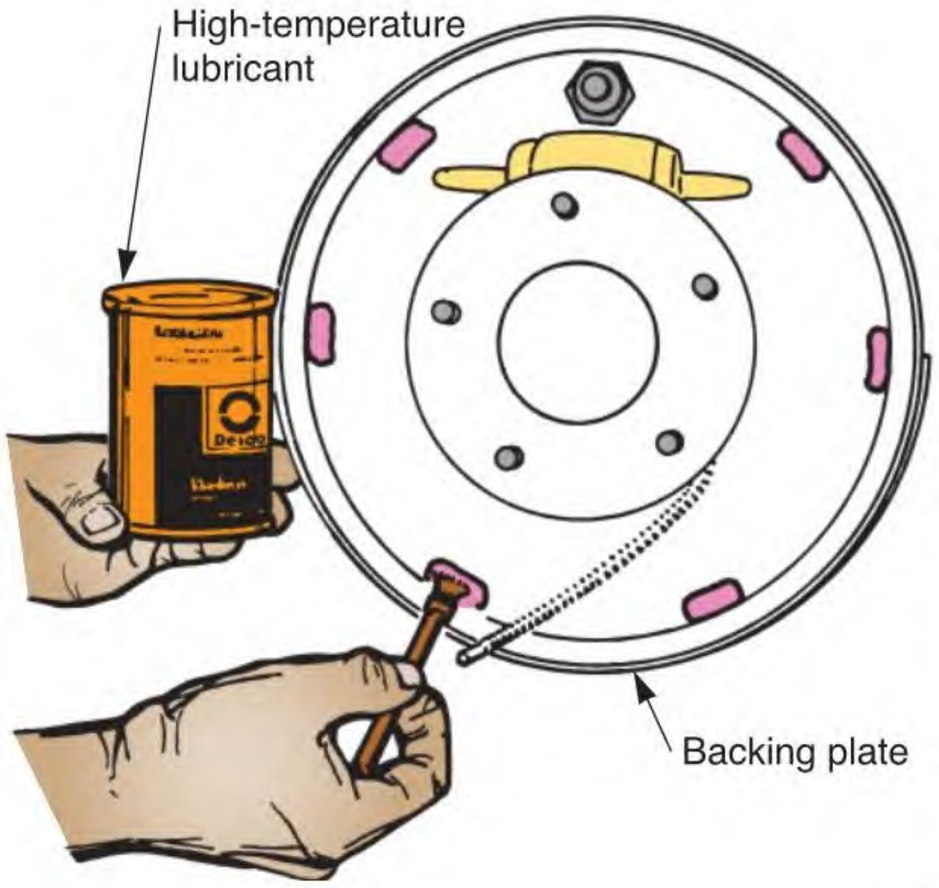


Figure 81-31. Note how this drum is mounted on the brake lathe. A shoe grinder is also shown.

Toyota; Chrysler; FMC

Figure 81-32. Note how to check brake drum wear. A—Drum diameter is the distance across the inside friction surface. B—Drum diameter is normally stamped on the outside of the drum. Oversize limits may also be given. C—A special drum micrometer will quickly and accurately measure drum diameter and wear. Generally, drums should not be more than 0.060″ (1.5 mm) oversize.

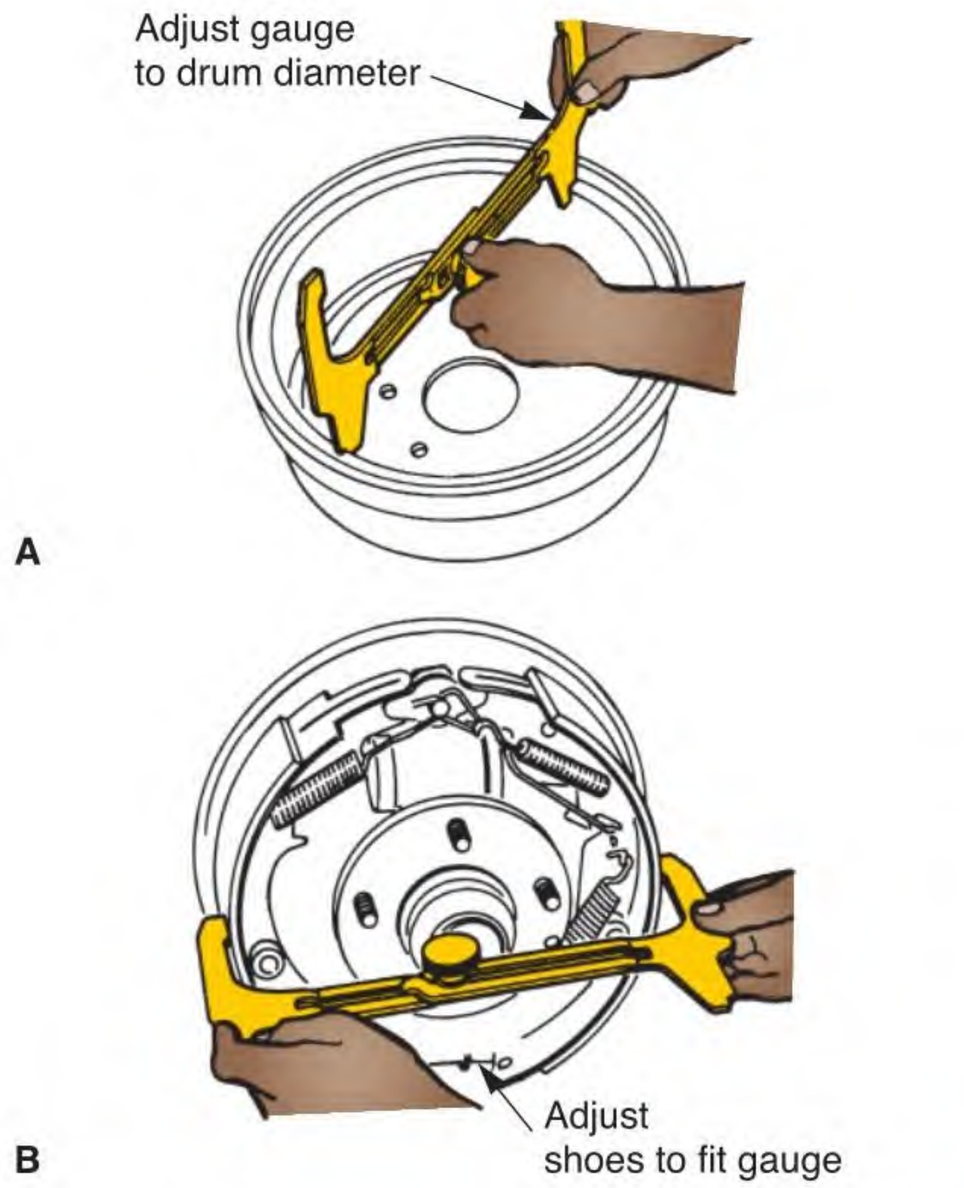
Bendix

Figure 81-33. Wipe high-temperature grease on the raised pads on the backing plate and on the star wheel threads.

Goodheart-Willcox Publisher

Figure 81-34. When assembling brakes, make sure every part is in the proper location. This illustration shows the locations for one specific unit.

- Are the shoes centered on the backing plate?
- Are the shoes contacting the anchor correctly?
- Are all the springs installed properly?
- Does the automatic adjuster work?
- Are the lining surfaces perfectly clean (sand if needed)?
- Do I need to bleed the brakes?



Your service manual will have assembly illustrations for the particular brake design being serviced. Use them to help position the parts on the backing plate correctly.

Preadjusting Drum Brakes

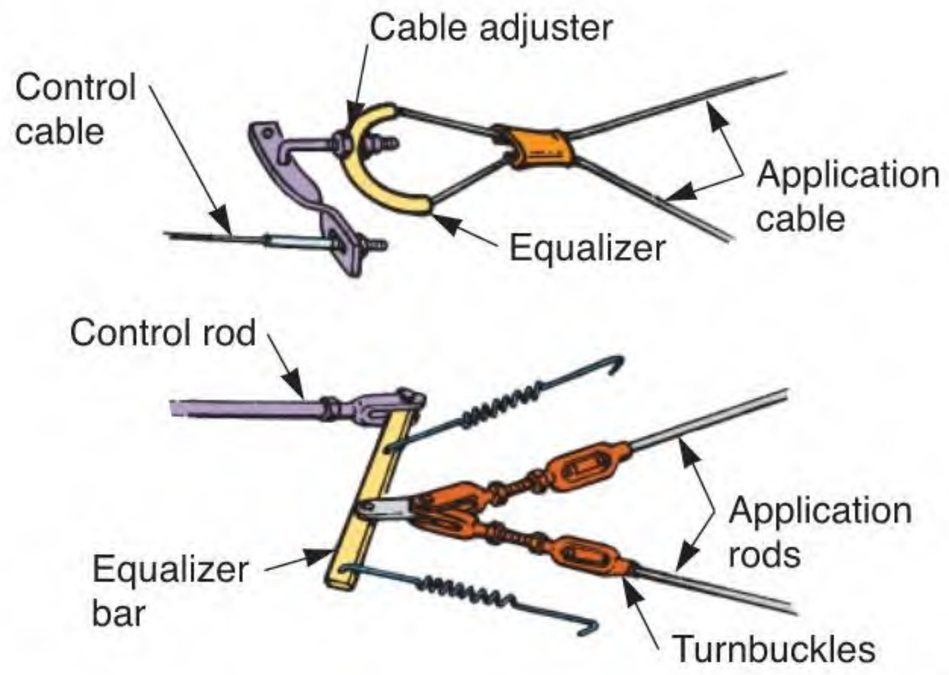
Even though modern brakes have automatic adjusters, you should preadjust the brake shoes. This will ensure proper initial brake system operation.

To preadjust the brake shoes, fit a brake adjusting gauge into the brake drum, **Figure 81-35A**. Set the gauge for the inside diameter of the drum. Tighten the lock on the gauge.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 81-35. Study drum brake preadjustment. A—Fit the gauge into the brake drum and adjust it against the inside diameter of the drum. Lock the unit into position. B—Fit the gauge around the outside of the brake shoes. Adjust the shoes outward until they just touch the gauge.



Next, fit the gauge over the brake shoes, **Figure 81-35B**. Then, turn the star wheel or move the adjuster arm until the linings touch the gauge. This will ensure that the linings are the correct distance from the inside of the drum.

Another way to preadjust drum brakes involves the use of a brake spoon (star wheel tool) to turn the star wheel. Turn the wheel until the brake drums drag lightly when rotated by hand.

Parking Brake Adjustment

To adjust the parking brake, you must normally tighten an adjustment nut on the cable mechanism. Refer to **Figure 81-36**.

During adjustment, release the parking brake lever or pedal. Lubricate cables and linkages. To prevent over adjustment, engage the parking brake lever or pedal one notch. Then, turn the cable adjuster to remove excess slack. Operate the parking brake and make sure the brakes are not dragging when released.

FMC

Figure 81-36. Note how to adjust parking brake. Simply turn the threaded fastener or the turnbuckle until excess slack is out of the cable. Do not overtighten the parking brake, or the brakes can drag and overheat.

Diagnostic Case Study

Concern: Mr. Jenson brings his 2012 Ford F-150 pickup to the shop and says that his brake pedal goes all the way to the floor at stoplights. He says that new brake pads were installed only a few weeks earlier.

Cause: Duff checks the fluid level in the master cylinder and finds it to be normal. He tests the brake pedal action and finds that it feels soft and bleeds down to the floor with constant foot pressure. Since fluid is not leaking from the system, this indicates internal leakage in the master cylinder. Duff turns the repair over to the shop's brakes specialist.

Correction: The technician removes the old master cylinder. She fills the new master cylinder with brake fluid and bench bleeds it before installing it on the vehicle. After the new master cylinder is installed in the vehicle, the technician uses a pressure bleeder to bleed air out of the entire brake system. She checks the brakes for proper operation and then releases the vehicle to the customer.

Copyright Goodheart-Willcox Co., Inc.

Summary

- Use symptoms (noises, smells, abnormal brake pedal movements, improper braking action) when diagnosing brake system problems.
- Modern brake systems, primarily those with anti-lock brake systems, have self-diagnostic capabilities.
- Brake vibration shows up as a chatter, pulsing, or shake. It happens only when the brake pedal is applied.
- Grabbing is a condition in which the brakes apply too quickly, with only light brake pedal application.
- Pulling brakes is a symptom in which the vehicle veers to the right or left when braking.
- A spongy brake pedal is a condition which causes the brake pedal to feel like it is connected to a spring or rubber band.
- A dropping brake pedal is a symptom in which the brake pedal slowly moves all the way to the floor when steady pressure is applied to it.
- Dragging brakes are brakes that remain partially applied even though the brake pedal is released.
- Brake pedal height is the distance from the pedal to the floor fully released.
- Brake pedal free play is the amount of pedal movement before the beginning of brake application.
- Typically, the brake fluid level should be 1/4″ (6 mm) from the top of the reservoir.
- When the fluid level in the master cylinder is low, you should inspect the brake system for leaks.
- When inspecting disc brakes, check the thickness of the brake pad linings. Pads should be replaced when the thinnest (most worn) part of the lining is no thicker than the metal shoe (approximately 1/8″ or 3 mm).
- A faulty master cylinder usually leaks fluid past the rear piston or leaks internally.
- A master cylinder is bench bled to remove air from inside the cylinder.
- Brake system bleeding is the use of fluid pressure to force air out of the brake line connections or wheel cylinder bleeder screws.
- Pressure bleeding a brake system is done using a pressure bleeder tank which contains pressurized brake fluid.
- Vacuum bleeding a brake system requires a special vacuum tool connected to shop air pressure and to the bleeder screw of each wheel brake assembly.
- Brake disc runout is the amount of side-to-side movement measured on the outer friction surface of the rotor.
- Brake disc thickness is measured across the two friction surfaces in several locations.
- A wheel cylinder rebuild normally involves honing the cylinder and replacing the rubber cups and boots.
- Parking brake service includes inspecting, adjusting, and lubricating the mechanical cables and linkages of the system.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

bench bleeding
brake disc resurfacing
brake disc runout
brake disc thickness
brake drum grinding
brake drum resurfacing
brake fluid level
brake pedal check
brake pedal free play
brake pedal height
brake pedal reserve distance
brake system bleeding
brake system flushing
brake vibration
brake warning light
braking noise
disc brake service
dragging brakes
dropping brake pedal
drum brake service
excessive brake pedal effort
grabbing brakes
heat checked
low brake pedal
manual bleeding
master cylinder filling tool
no brake pedal
pressure bleeding
pulling brakes
spongy brake pedal
turning
vacuum bleeder tool
vacuum bleeding
vibration damper
wheel cylinder rebuild

Activities

1. Demonstrate the safe method of removing asbestos laden dust from a brake assembly.
2. Bleed a set of brakes and explain your procedure.

Copyright Goodheart-Willcox Co., Inc.

3. Using a flat rate manual and a parts catalog, prepare a bill for a brake job.
4. Using a labor rate set by your instructor and a price list for parts, add up the cost of the brake job. Fill in the price on the bill prepared in Activity 3.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What usually causes brake pedal vibration?
2. _____ brakes apply too quickly, even with light pedal application.
3. _____ brakes cause the vehicle to steer to the right or left when braking.
4. A spongy brake pedal is normally caused by air in the brake system. True or False?
5. A driver complains that the brake pedal slowly moves toward the floor when the vehicle is stopped at traffic lights. Pumping the pedal temporarily returns the pedal to the proper height. Also, the brake fluid has been checked and is at a normal height in the reservoir. Technician A says that a bad master cylinder could be the cause of the problem. Fluid could be leaking internally in the cylinder. Technician B says that a leaking wheel cylinder could be allowing pressure to drop. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. List and explain three types of brake noise.
7. Which of the following is *not* a brake pedal measurement?
   (A) Brake pedal free play.
   (B) Brake pedal pressure.
   (C) Brake pedal height.
   (D) Brake pedal reserve distance.
8. How much fluid should typically be in a master cylinder?
9. How do you check brake pad lining wear and brake shoe lining wear?
10. How do you quickly test the basic operation of a vacuum brake booster?
11. Most technicians replace faulty master cylinders with new or factory rebuilt units. True or False?
12. Cleaning hydraulic brake system parts in cold soak solvent is recommended. True or False?
13. A master cylinder should be _____ before installation to remove air from the unit.
14. What are the three methods for bleeding a vehicle brake system?
15. List the four major operations done during disc brake service.
16. _____ is the amount of side-to-side movement measured near the outer friction surface of a disc.
17. What can happen if a brake disc is too thin?
18. List the seven major steps for drum brake service.
19. Typically, a brake drum should *not* be _____ oversize, or it can warp or break.
20. Summarize the preadjustment procedure for drum brakes.
21. A technician determines that an automobile's front brake pad linings are 0.025″ thick. Specifications call for a minimum thickness of 0.020″. How much are the pads in or out of specifications?
   (A) 0.005″ out of specifications.
   (B) 0.005″ within specifications.
   (C) 0.045″ out of specifications.
   (D) 0.045″ within specifications.

ASE-Type Questions

1. A service writer says a customer's car has a brake system problem. Technician A road tests the car to detect any strange noises. Technician B checks the car around the master cylinder, brake lines, and wheel assemblies for any unusual odors. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. A customer complains that his car vibrates when the brake pedal is applied. Technician A looks for a warped disc. Technician B checks for "hard spots" on the brake disc. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

3. A car is brought into the shop with grabbing brakes. Technician A looks for worn brake linings. Technician B looks for a faulty metering valve. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. A customer tells the shop service writer that there has been a noticeable increase in the amount of foot pressure needed to apply the brakes on her car. Technician A checks for a frozen wheel cylinder. Technician B checks the car's front end alignment. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. A car veers to the right when the brakes are applied. Technician A checks the vehicle's front end alignment. Technician B looks for a frozen caliper. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. An automobile's brake system has a soft, spongy pedal. Technician A checks the fluid level in the master cylinder. Technician B checks the operation of the brake caliper pistons. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. An automobile has a dropping brake pedal. Technician A looks for an internal master cylinder leak. Technician B checks for a scored or gouged brake rotor. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. A car has a low brake pedal problem. Technician A inspects the brake adjusters. Technician B looks for a maladjusted master cylinder push rod. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. An automobile's brakes are dragging. Technician A checks the parking brake adjustment. Technician B checks for a master cylinder malfunction. Who is right?
   (A) A only.
   (B) B only.

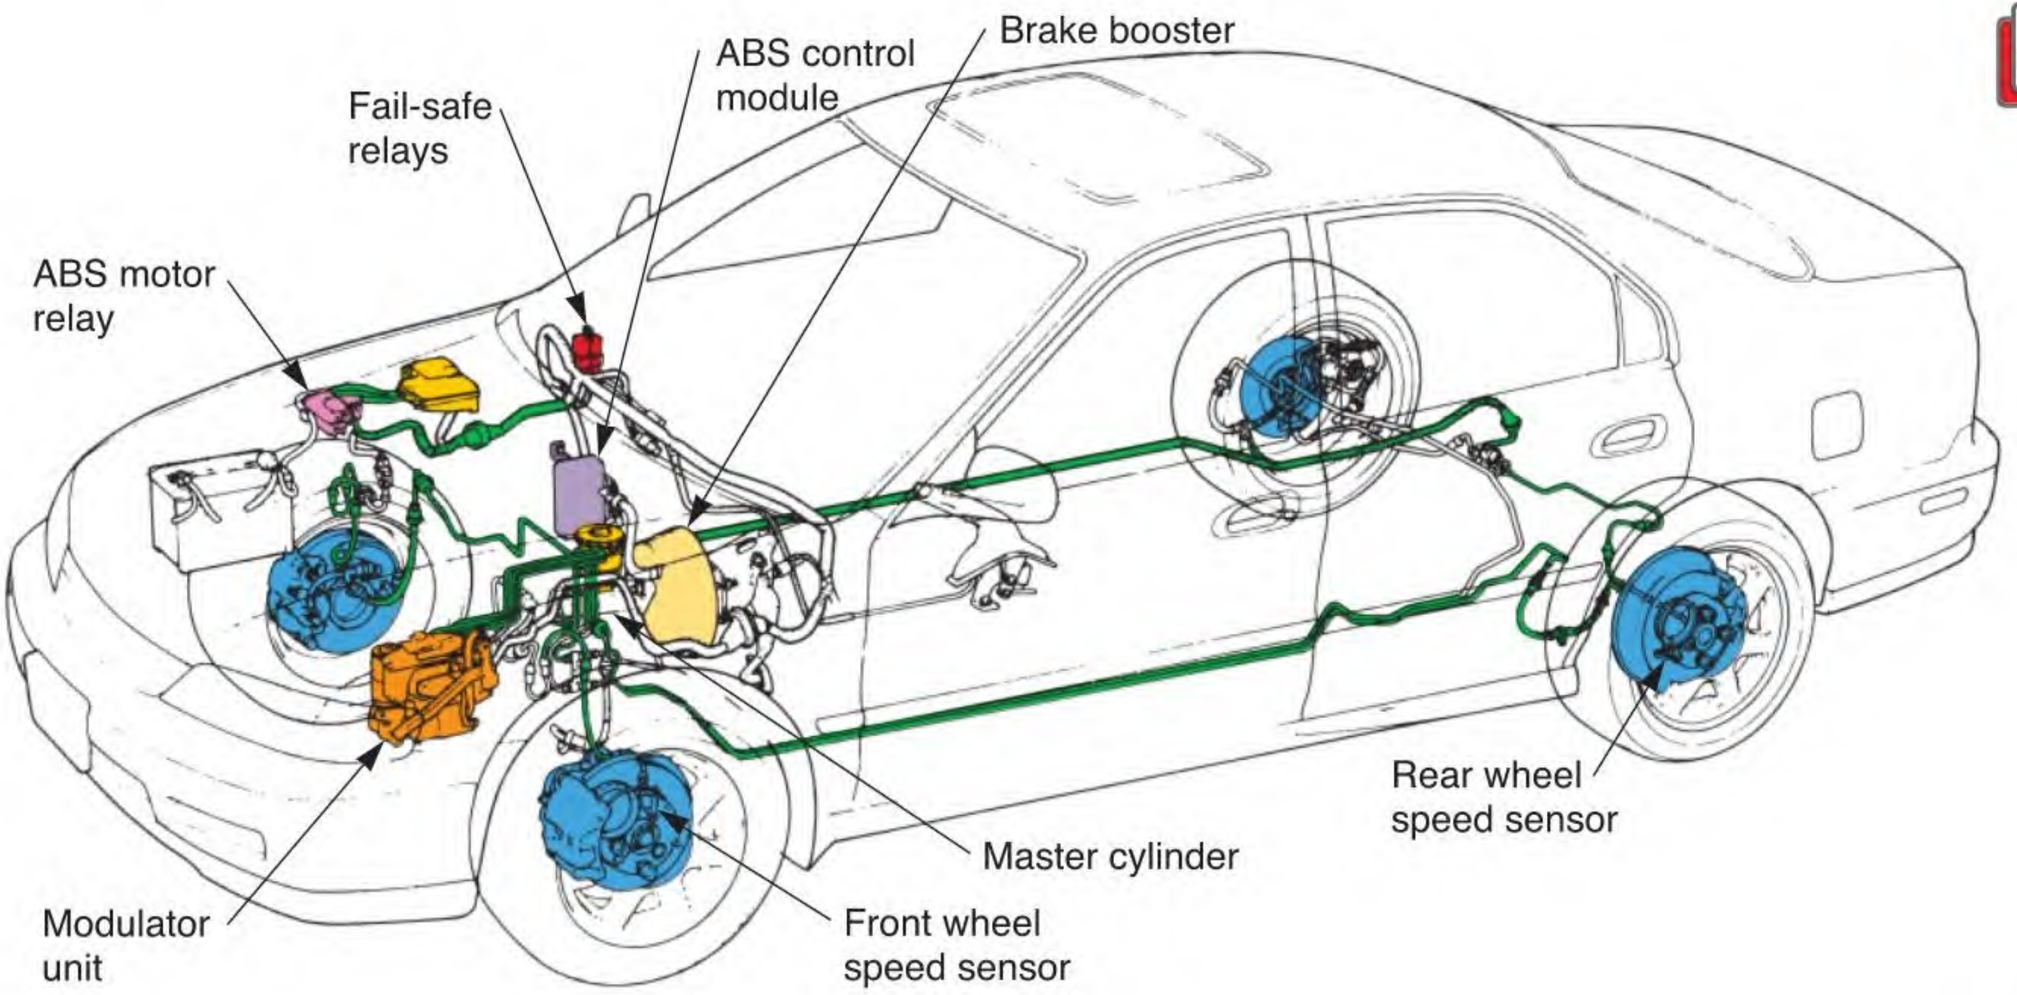
Chapter 82
Anti-Lock Brakes, Traction, and Stability Control

After studying this chapter, you will be able to:

- Identify the major parts of a typical anti-lock brake system.
- Describe the operation of anti-lock brake systems.
- Compare anti-lock brake design variations.
- Describe the purpose and operation of traction control and stability control systems.
- Diagnose problems in anti-lock brake systems.
- Repair anti-lock brake systems.
- Diagnose and repair traction control and stability control systems.
- Correctly answer ASE certification test questions requiring knowledge of anti-lock brake systems, traction control systems, and stability control systems.

Anti-lock brake systems, or ***ABS***, are standard equipment on economy cars, luxury cars, minivans, and even pickup trucks. The major parts of a modern anti-lock brake system are illustrated in **Figure 82-1**.

ABS increases safety by reducing stopping distances compared to manual brakes on both wet and dry pavement. The ABS control module can cycle hydraulic pressure to each caliper or wheel cylinder to prevent wheel lockup. When a wheel locks up, its tire begins to skid and the coefficient of friction between the tire's tread and the road surface is diminished.



Traction control systems (TCS) electronically control the brakes, differential, engine, and transaxle to help reduce tire spin upon acceleration on slippery pavement. Again, when a tire skids on a road surface, it loses traction or adhesion. By preventing a wheel and tire from spinning too rapidly, a car with a TCS can drive up a snowy hill better than a car with rapidly spinning, skidding tires.

Stability control systems electronically link the steering, suspension, braking, and traction control systems together to prevent a loss of vehicle control and skidding when cornering at high speed. Almost every sensor on the car will provide feedback on the car's performance: vehicle speed, transmission gear selection, braking force applied to pedal, degree and speed of steering wheel rotation, etc. Various control modules can then adjust shock stiffness, sway bar tension, brake application at each wheel, engine power output, transmission operation, and even differential lockup to keep the vehicle level and stable when braking and cornering.

This chapter will build on the information you learned in previous chapters. It will introduce the additional parts needed to provide computer control of the complete chassis and driveline.

The chapter also summarizes the operation and repair of traction control and stability control systems.

Honda

Figure 82-1. A modern anti-lock brake system uses a control module (computer), sensors, and a modulator to aid panic stops or stops on slick pavement. Also, note the locations of the relays.

These systems often use parts of the anti-lock brake system to help prevent tire spin and skidding to increase driver safety during emergency maneuvers.

Anti-Lock Brake Systems (ABS)

ABS uses wheel speed sensors, an ABS control module (computer), an electro-hydraulic brake actuator, and conventional hydraulic brake circuits to prevent wheel lockup during hard braking.

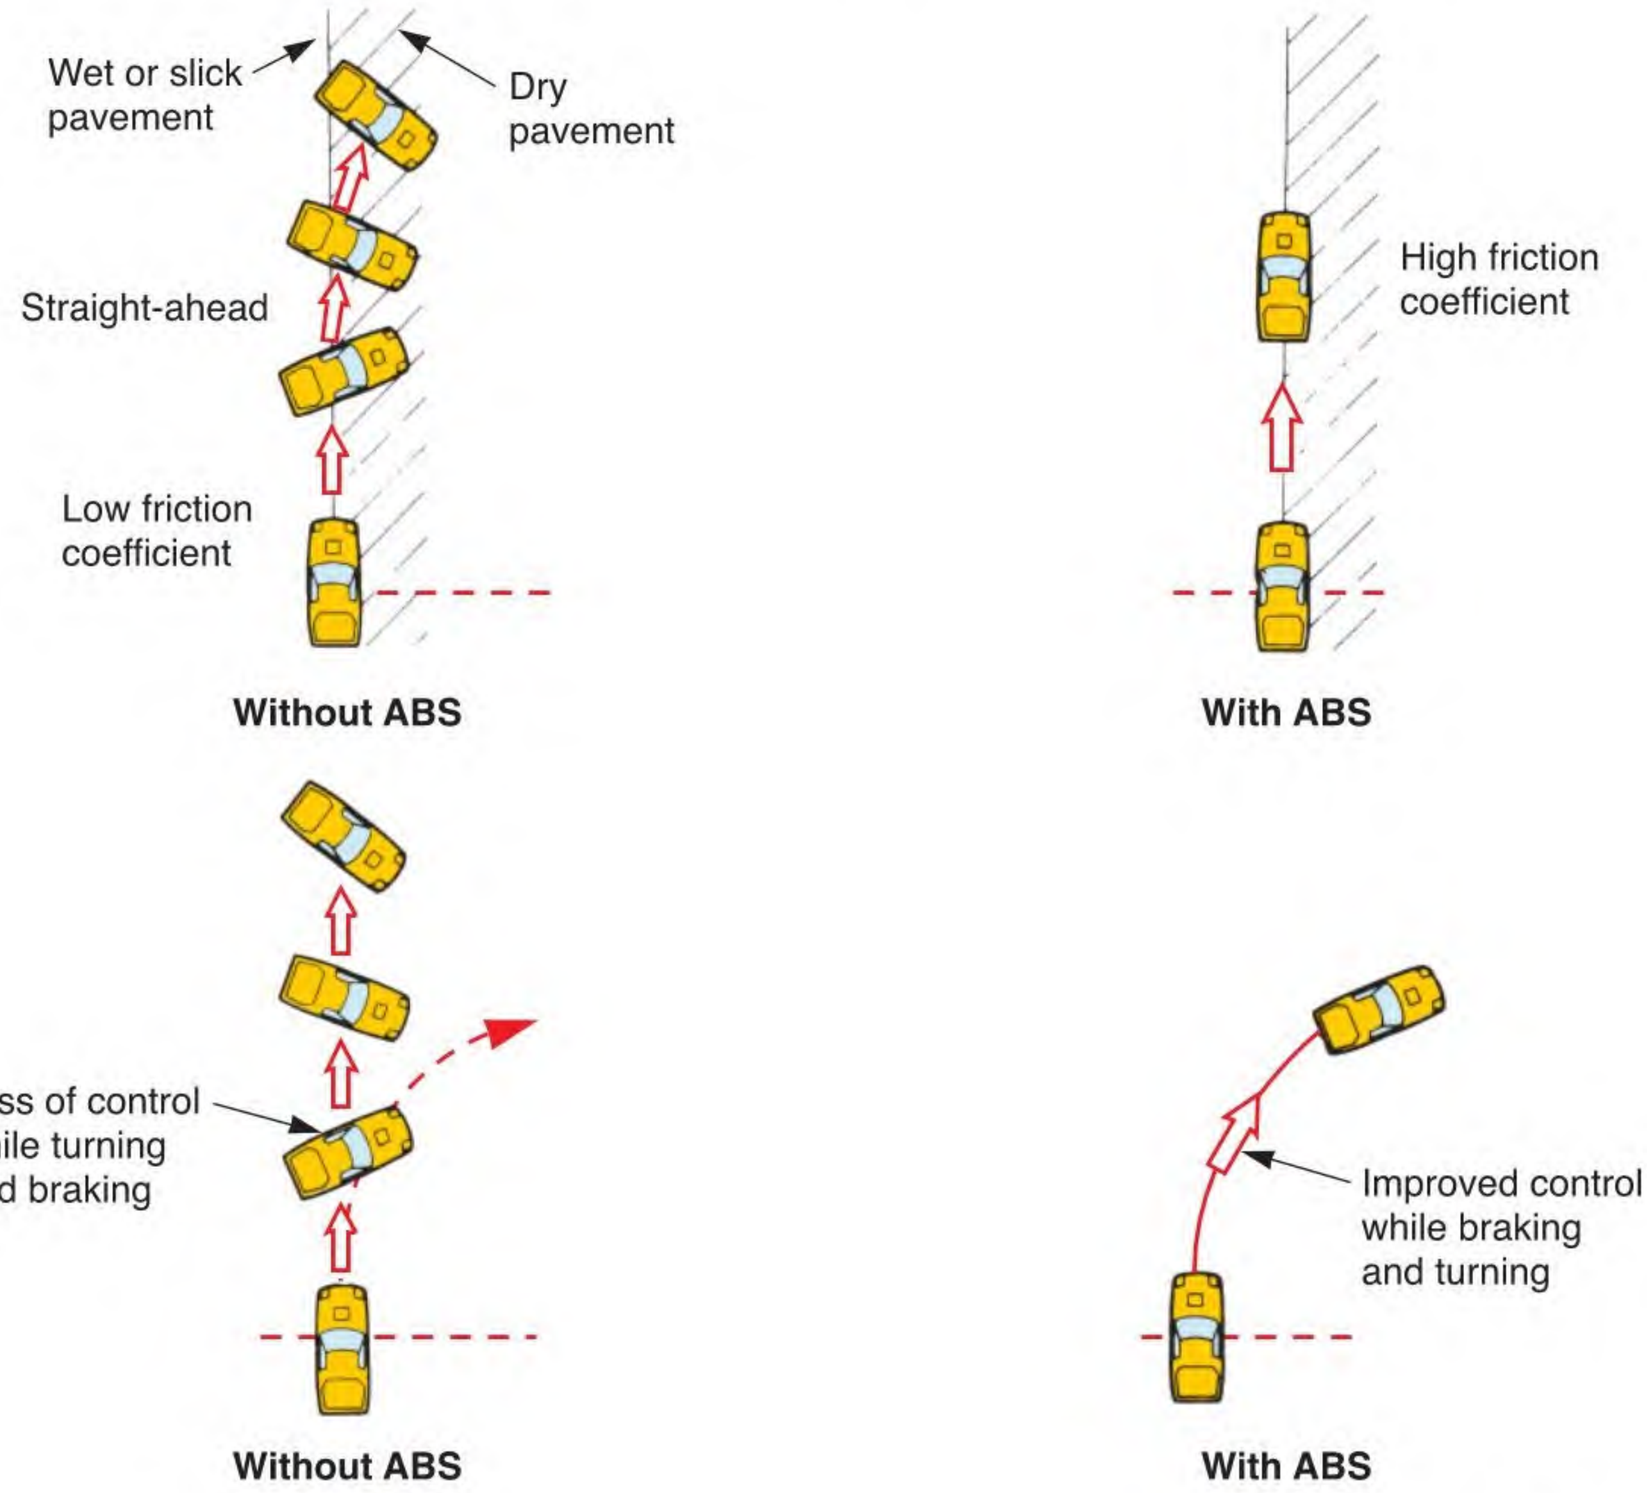
If a wheel locks up and the tire skids on the road surface, braking distance will increase and steering control can be lost. In a panic stop situation, the driver will often press down hard on the brake pedal to try to avoid a collision. This will normally send too much hydraulic pressure to the wheel cylinders, locking the wheels on vehicles without ABS. The tires will begin to squeal as they slide over the road surface. When the tires skid, they actually lose traction or friction with the road surface. This can increase stopping distance and reduce vehicle control in some situations.

On dry pavement, good drivers only apply enough pedal pressure to almost reach tire skid. They will release pedal pressure slightly when the squeal of tire skid is heard or felt. On slick pavement (water, snow, or ice on road surface), good drivers might pump the brake pedal manually to reduce skidding and stopping distance.

This is the principle of anti-lock brakes. For maximum stopping power, you want the tires to almost, but not quite, skid. When the tire skids, its friction with the road surface drops and stopping distance increases, which could cause an accident.

The anti-lock brake system improves driver and passenger safety by reducing stopping distances and increasing directional stability under panic stop conditions.

Figure 82-2 shows the advantages of ABS. In this example, one side of the road is very slippery and the other side is dry. This poses a problem if a panic stop is required.



Without ABS, the car would tend to skid to the right because of higher tire adhesion on the right. With ABS, the car would still travel straight-ahead with hard braking. The brake units would be cycled to prevent tire skid and a loss of control. Also note that the car can be steered while braking with ABS.

ABS Components

The major parts of an anti-lock braking system, **Figure 82-3**, include:

- Wheel speed sensors—The wheel speed sensors are magnetic pickups for detecting the rotating speed of each tire and wheel assembly.
- Sensor trigger wheels—Sensor trigger wheels are toothed wheels that rotate at the same speed as the wheel and tire.

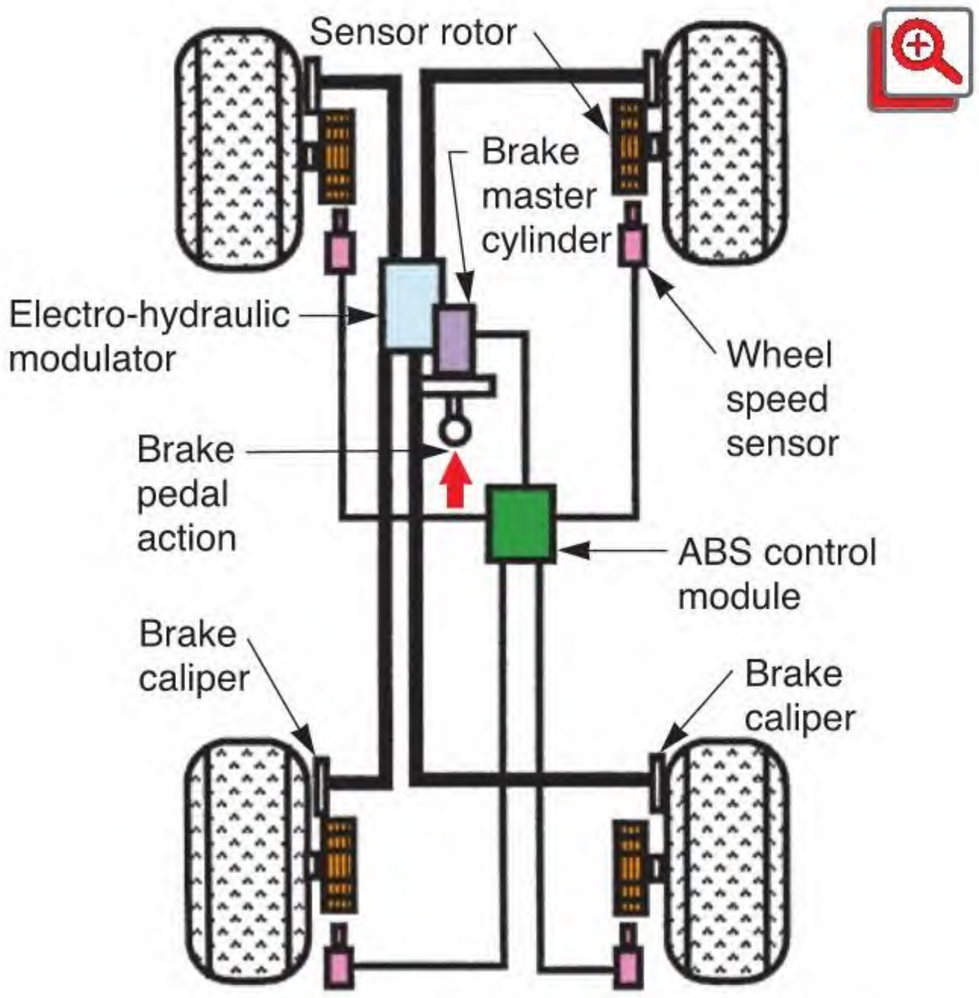
Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 82-2. Without ABS, tires can lock up and lose adhesion with the road. This can cause a loss of control during hard braking or when braking and trying to steer. Even if one side of the road is slick, the brakes will be cycled so that none of the tires skid. Maximum braking results when tires are just about ready to skid; traction is reduced if the wheels lock up.

- ABS control module—This module is a small computer, or processor, that uses sensor inputs to control the electro-hydraulic modulator.
- Electro-hydraulic modulator—The electro-hydraulic modulator is a control module-operated solenoid valve and electric pump module that cycles pressure to each wheel brake cylinder if its speed begins to slow down too much, indicating tire skid or wheel lockup.
- Brake warning light—This light, which is located in the instrument cluster, informs the driver of problems in the anti-lock brake system circuits.

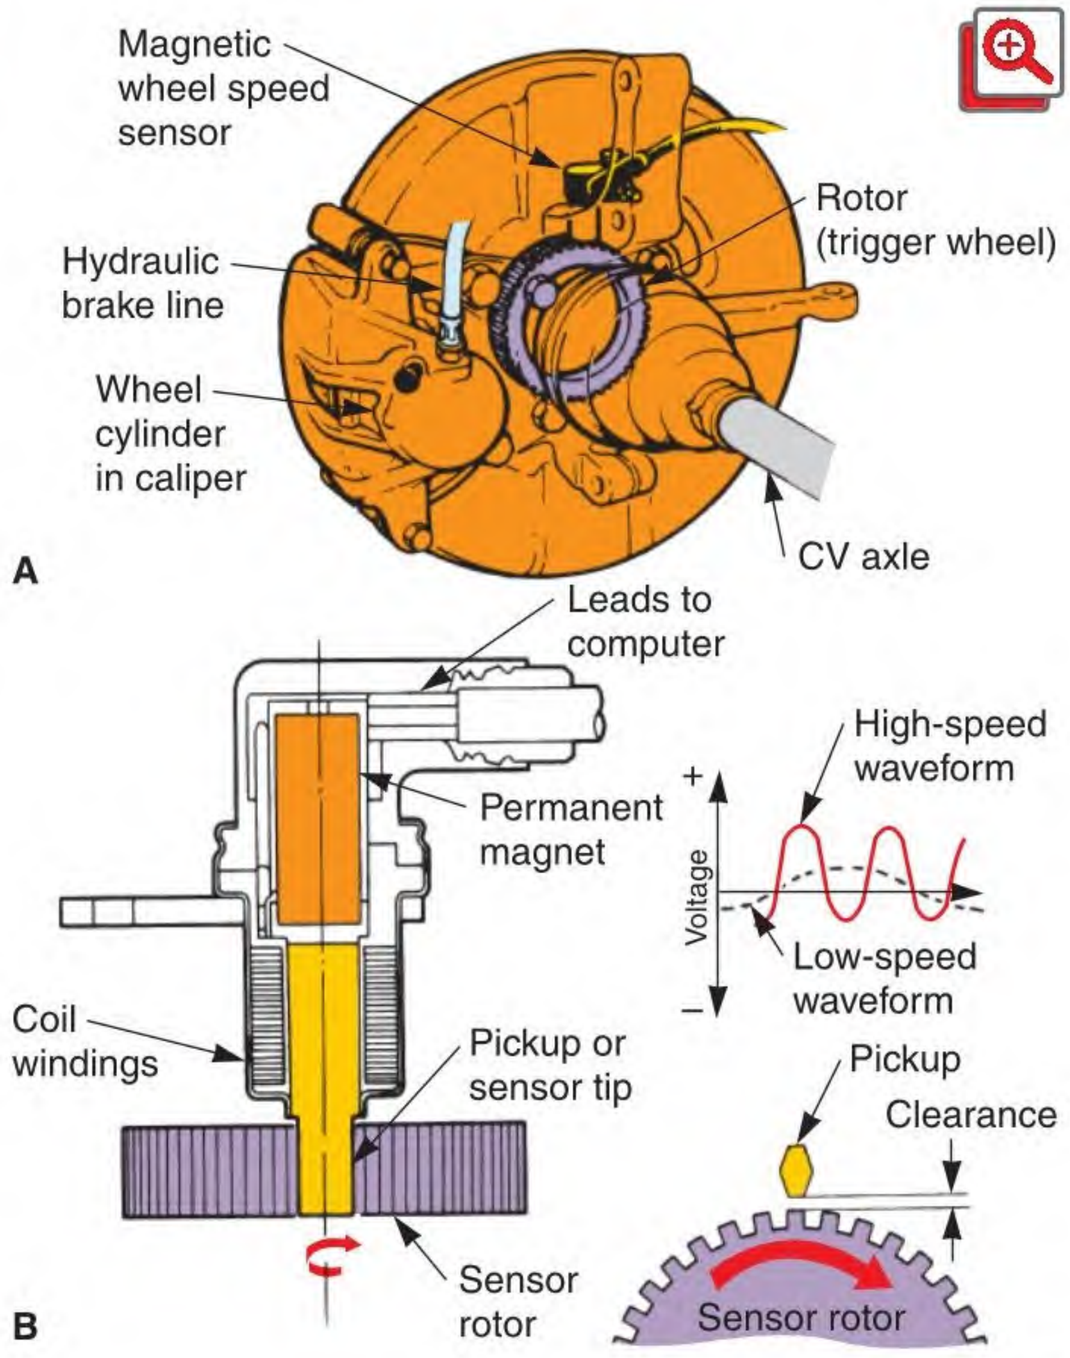
Wheel Speed Sensors



The ***wheel speed sensors*** produce ac signals that correspond to wheel and tire speed. These signals are fed into the ABS control module. With rear-wheel anti-lock brakes, wheel speed sensors are only used on the rear wheels. With four-wheel anti-lock brakes, wheel speed sensors are needed on all wheels. Refer to **Figure 82-4**.

The ***sensor rotor***, or ***trigger wheel***, is a toothed ring that rotates with the wheel hub. The magnetic sensor tip is located next to the sensor rotor teeth. Only a small ***air gap*** separates the sensor tip from the spinning teeth.

As the tire and wheel rotates, the sensor rotor spins. As each rotor tooth passes the sensor, the magnetic field around the sensor is affected. This induces a weak ac signal in the wheel sensor coil, **Figure 82-4**.



The frequency of this wheel speed sensor's ac signal depends on tire and wheel speed. As the tire rotates faster, a higher frequency signal is sent back to the ABS control module. If tire rotation slows, a lower frequency signal is almost instantly fed to the ABS control module.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 82-3. Note basic parts of an anti-lock brake system. Sensor rotors are mounted on each spindle. Magnetic sensor coils produce an ac signal that equals wheel speed. The ABS control module can detect if one or more wheels are skidding because the sensor signal will decrease in frequency. The control module can then trigger the electro-hydraulic modulator to cycle hydraulic pressure to keep the tires from skidding and losing traction.

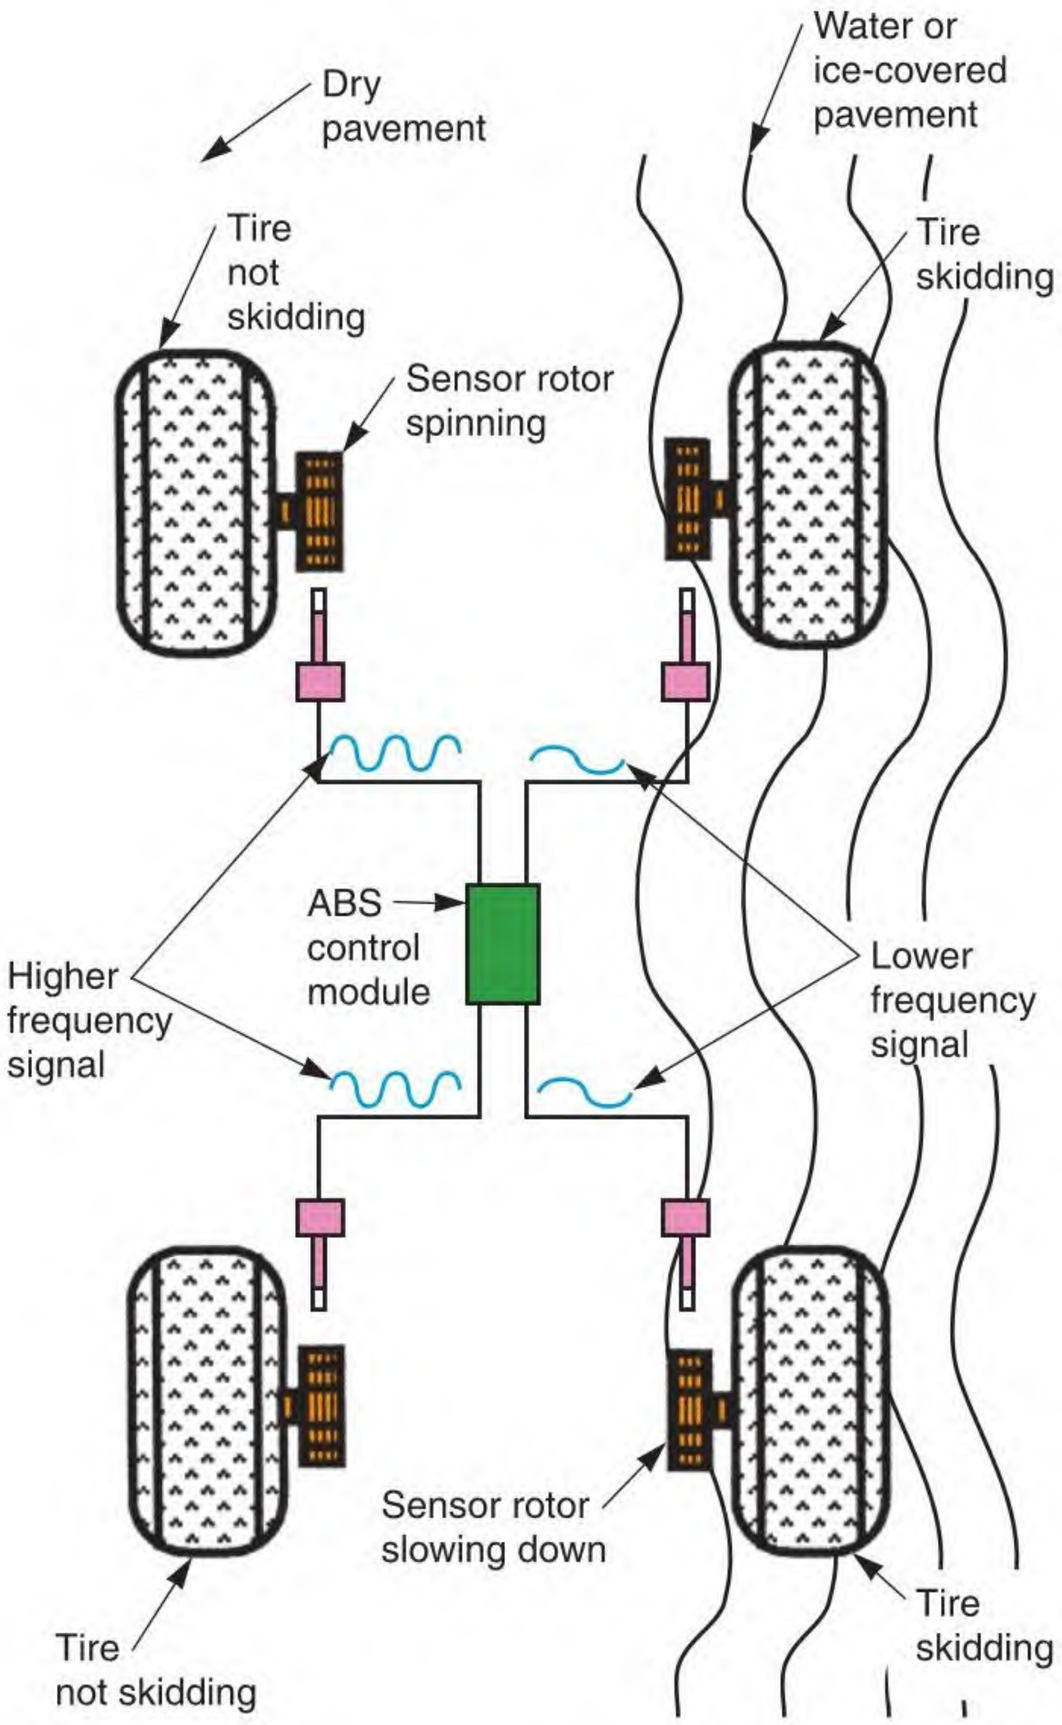
Saab

Figure 82-4. Study how a wheel speed sensor generates weak ac signal for the ABS control module. A—Wheel speed sensor is mounted next to the sensor rotor. As the tire rotates, teeth on the rotor make the magnetic sensor produce a 1.5-volt ac signal for the ABS control module. B—Current is induced in the sensor windings as teeth pass the sensor. Note the waveform. Specific clearance is needed between the sensor and rotor teeth if the sensor is to generate the proper voltage signal.

The ac signal is used by the ABS control module to check for tire skid. A rapid decrease in sensor ac signal frequency would indicate that a tire is starting to lock up and skid. The control module would then send an electrical signal to the electro-hydraulic modulator to pulsate hydraulic pressure to the affected wheel cylinder. Study **Figure 82-5**.

ABS Control Module

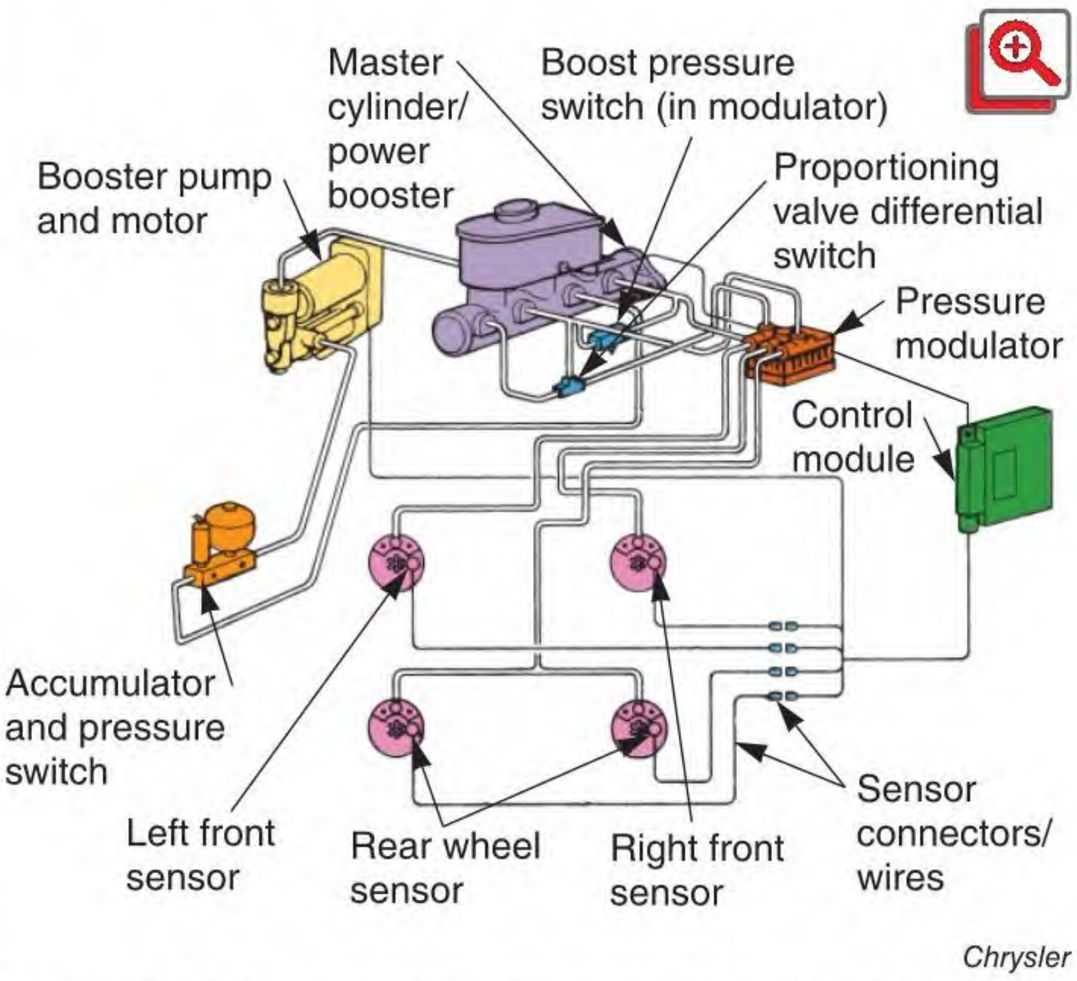
The ***ABS control module*** is a small computer that uses wheel speed sensor inputs to control the operation of the electro-hydraulic modulator. It is constructed and operates like the other control modules discussed in this book. See **Figure 82-6**.



ABS Electro-Hydraulic Modulator

The ***ABS electro-hydraulic modulator***, also called an ***ABS actuator***, regulates the fluid pressure applied to each wheel brake assembly during periods of hard braking. The modulator is controlled by the ABS control module. It is often mounted on the firewall in the engine compartment or somewhere in the passenger compartment, **Figure 82-7**.

The following are major parts of an ABS modulator:



- ***Brake fluid reservoir***—The brake fluid reservoir is a container for holding an extra supply of brake fluid. See **Figure 82-8**.
- ***Brake solenoid valve block***—The brake solenoid valve block is an electro-hydraulic device that contains coil-operated valves that control brake fluid flow to each wheel brake cylinder.
- ***Brake accumulator***—The brake accumulator is a chamber for storing extra fluid under high pressure.
- ***Brake fluid pump and motor***—The brake fluid pump is a high-pressure pump operated by a small electric motor; it provides brake fluid pressure for the ABS system.
- ***Brake pressure switch***—The brake pressure switch is a sensor that monitors brake fluid pres-

Figure 82-5. Study how the frequency of the signal from the skidding tires is lower than the frequency from the tires that are rotating on dry pavement. This is how the ABS control module detects when a tire or tires are skidding to control hydraulic pressure to those wheel cylinders.

Chrysler

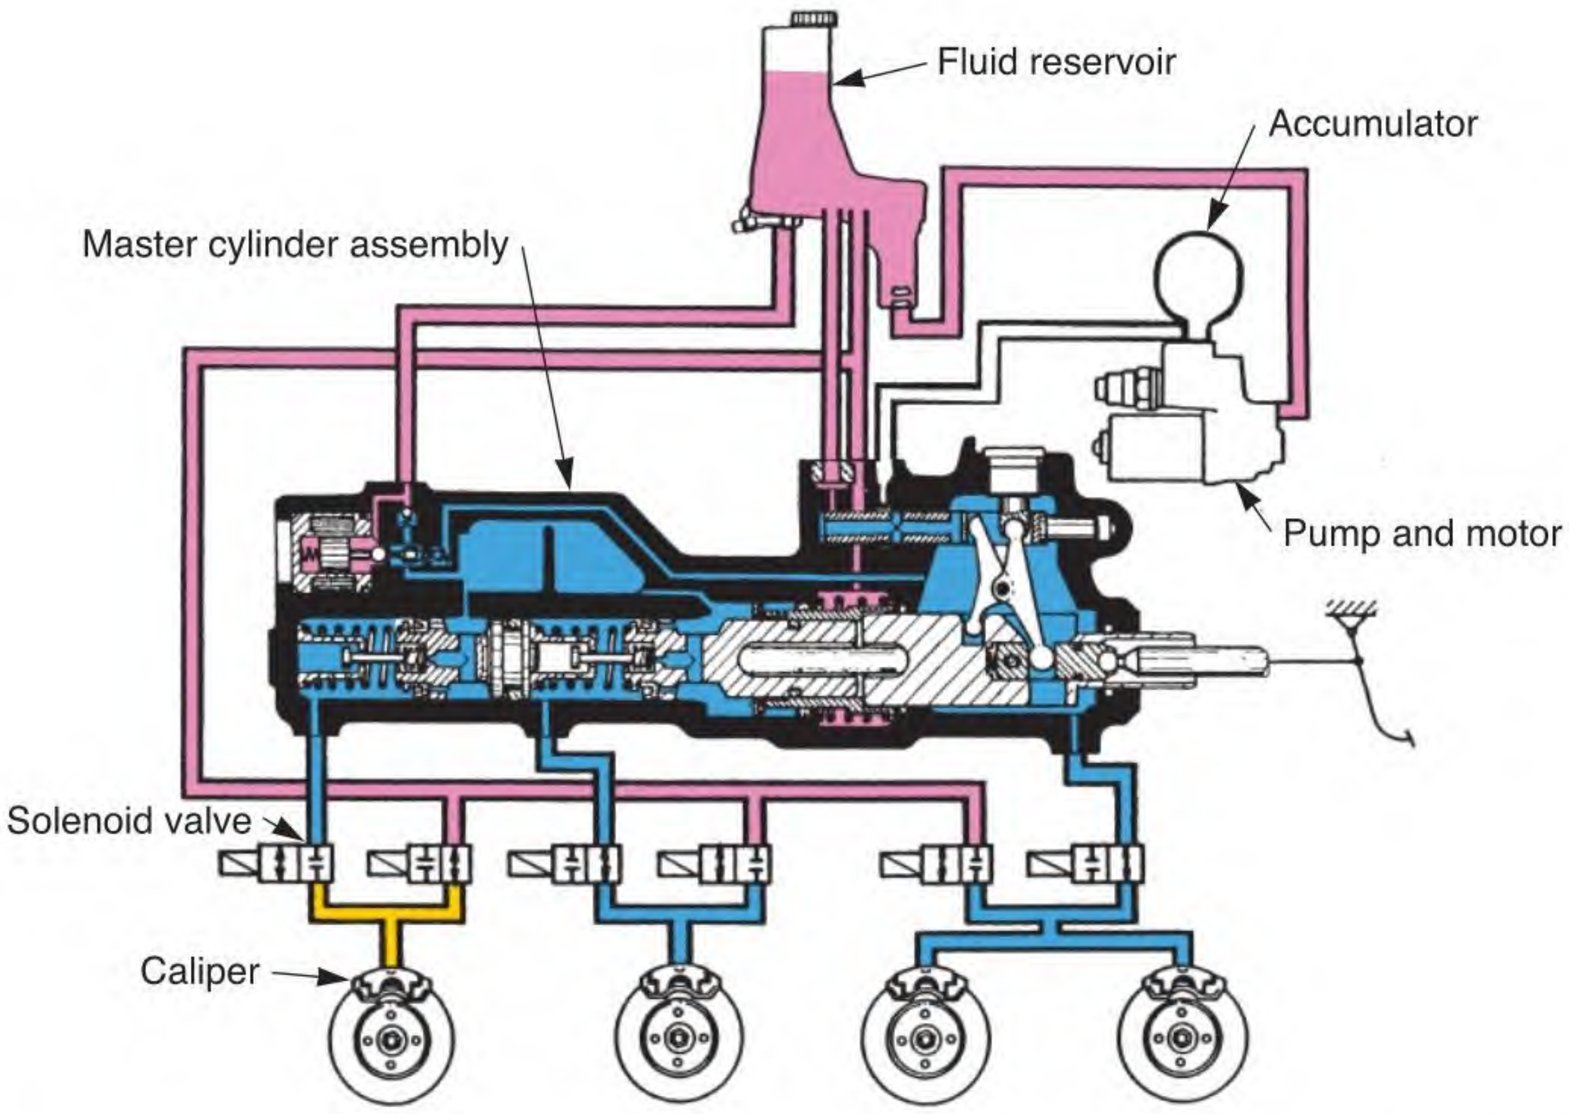
Figure 82-6. An accumulator stores an extra supply of fluid under pressure to increase fluid cycling rates and volume. An electric motor–driven pump produces pressure assist for this ABS system.

Snap-on Tool Corp.

Figure 82-7. ABS modulator, or electro-hydraulic unit, in an engine compartment. Note the wire connections and the brake fluid reservoir.

sure and controls operation of the electric motor for the hydraulic pump.

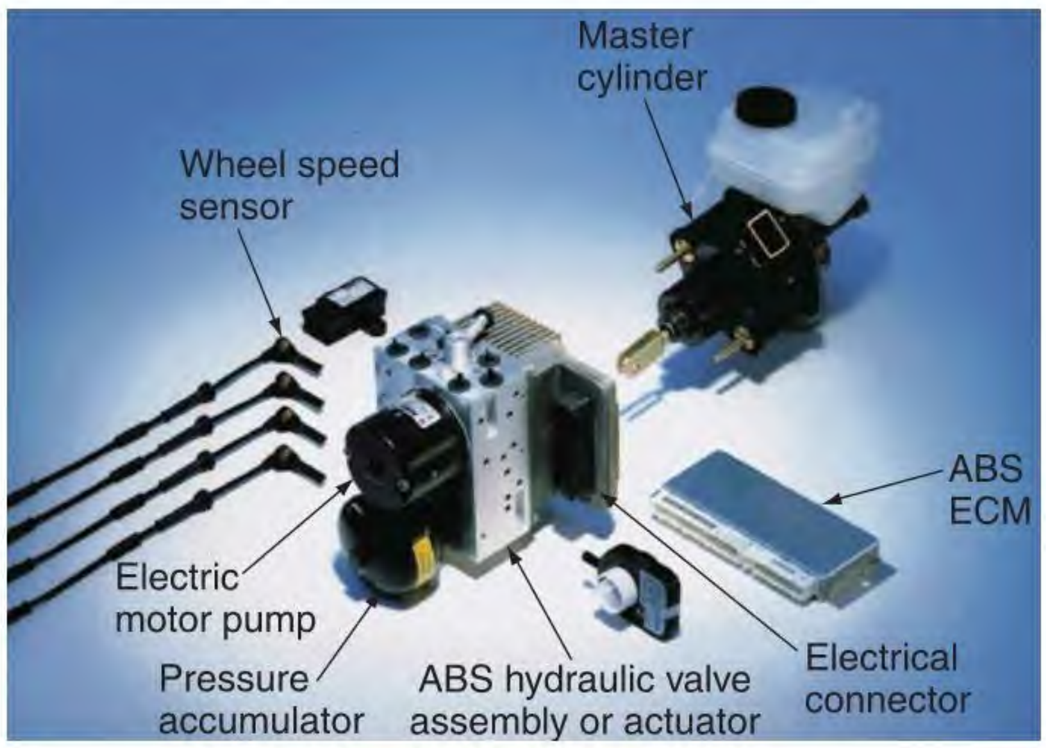
- ***Brake master cylinder-booster assembly***—The brake master cylinder-booster assembly is a conventional master cylinder with power assist for operating brakes under normal conditions, **Figure 82-9**.



ABS systems and hydraulic modulators vary with the specific make and model of car, van, or truck. However, their operating principles are very similar.

The primary purpose of the electro-hydraulic modulator is to produce hydraulic pressure pulses, or modulations.

An ***integrated ABS*** combines the power booster, master cylinder, and modulator units into one assembly. All these units are mounted together.



In a ***nonintegrated ABS***, the major units are separated. A conventional booster and master cylinder are used with a separate electro-hydraulic modulator.

Copyright Goodheart-Willcox Co., Inc.

Saab

Figure 82-8. Study this variation of an ABS system. Note how the system is blocking pressure to one of the wheel cylinders to keep the brakes from locking and causing the tires to skid. Solenoid valves are positioned in the brake lines to the wheel cylinders.

Bosch

Figure 82-9. Study the major parts of an anti-lock brake system. The hydraulic actuator has solenoid-operated valves that can reduce pressure to each wheel brake assembly. It is frequently mounted on the brake master cylinder assembly.

Hydraulic pressure modulation refers to the electro-hydraulic unit's ability to rapidly cycle pressure to the wheel cylinders or calipers on and off, preventing wheel lockup and skidding. Anti-lock systems can modulate the brakes about 15 to 20 times per second.

There are three modes of ABS pressure modulation: the isolation mode, the dump mode, and the reapply mode. In the ***isolation mode***, the ABS control module detects that a tire is starting to skid and energizes the modulator to isolate that hydraulic circuit from the other brake lines. The nonskidding wheel circuits work normally, but the ABS takes over the one hydraulic circuit with the slowing wheel.

In the ***dump mode***, the ABS releases hydraulic pressure to one or more of the brake wheel cylinders or calipers. This is done to stop tire skidding. Wheel circuits work normally, but the ABS takes over. The ECM will energize a solenoid that redirects brake fluid pressure away from the wheel brake assembly.

In the ***reapply mode***, the ABS applies hydraulic pressure to one or more of the wheel brake assemblies. This is done to reapply the brakes during pressure modulation.

These three control modes (isolation, dump, and reapply) happen in milliseconds (thousandths of a second). Several brake pumping cycles occur each second. This is much faster than a human could manually pump the brakes.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

With hydraulic pressure modulation, the driver can actually feel and sometimes hear the brake pedal pulsing up and down or vibrating. This is caused by the modulator unit cycling pressure on and off, trying to reduce tire skid. This is a basic way to check to see if the system is functioning.

ABS Warning Light

An ***ABS warning light*** is mounted in the dash. This light is used to alert the driver to an ABS malfunction. It is important to note that the light generally glows during engine cranking and stays on for several seconds after the engine starts. This lets you know that the system is armed and functioning.

ABS Channels

An ABS ***channel*** is a separate hydraulic circuit that feeds out to one or more wheel cylinders or caliper pistons. Anti-lock brake systems can have from one to four channels.

A ***one-channel ABS*** normally operates the rear wheel brakes together. Only one channel is provided for both rear wheels. The front wheel brakes are not controlled by the ABS in a one-channel system. This was one of the earliest types of ABS.

A ***two-channel ABS*** has two separate hydraulic circuits controlled by the electro-hydraulic modulator. For example, with rear-wheel ABS, each rear brake has its own hydraulic control circuit. Pickup trucks sometimes use two-channel ABS, because the rear of the vehicle is considerably lighter than the front. Help is needed to keep the rear wheels from skidding because there is less weight pressing down on the rear tires.

A ***four-channel ABS*** has a separate hydraulic control circuit for each wheel. This is the most effective and common anti-lock brake system found on late-model vehicles. It can keep any one of the four tires from skidding.

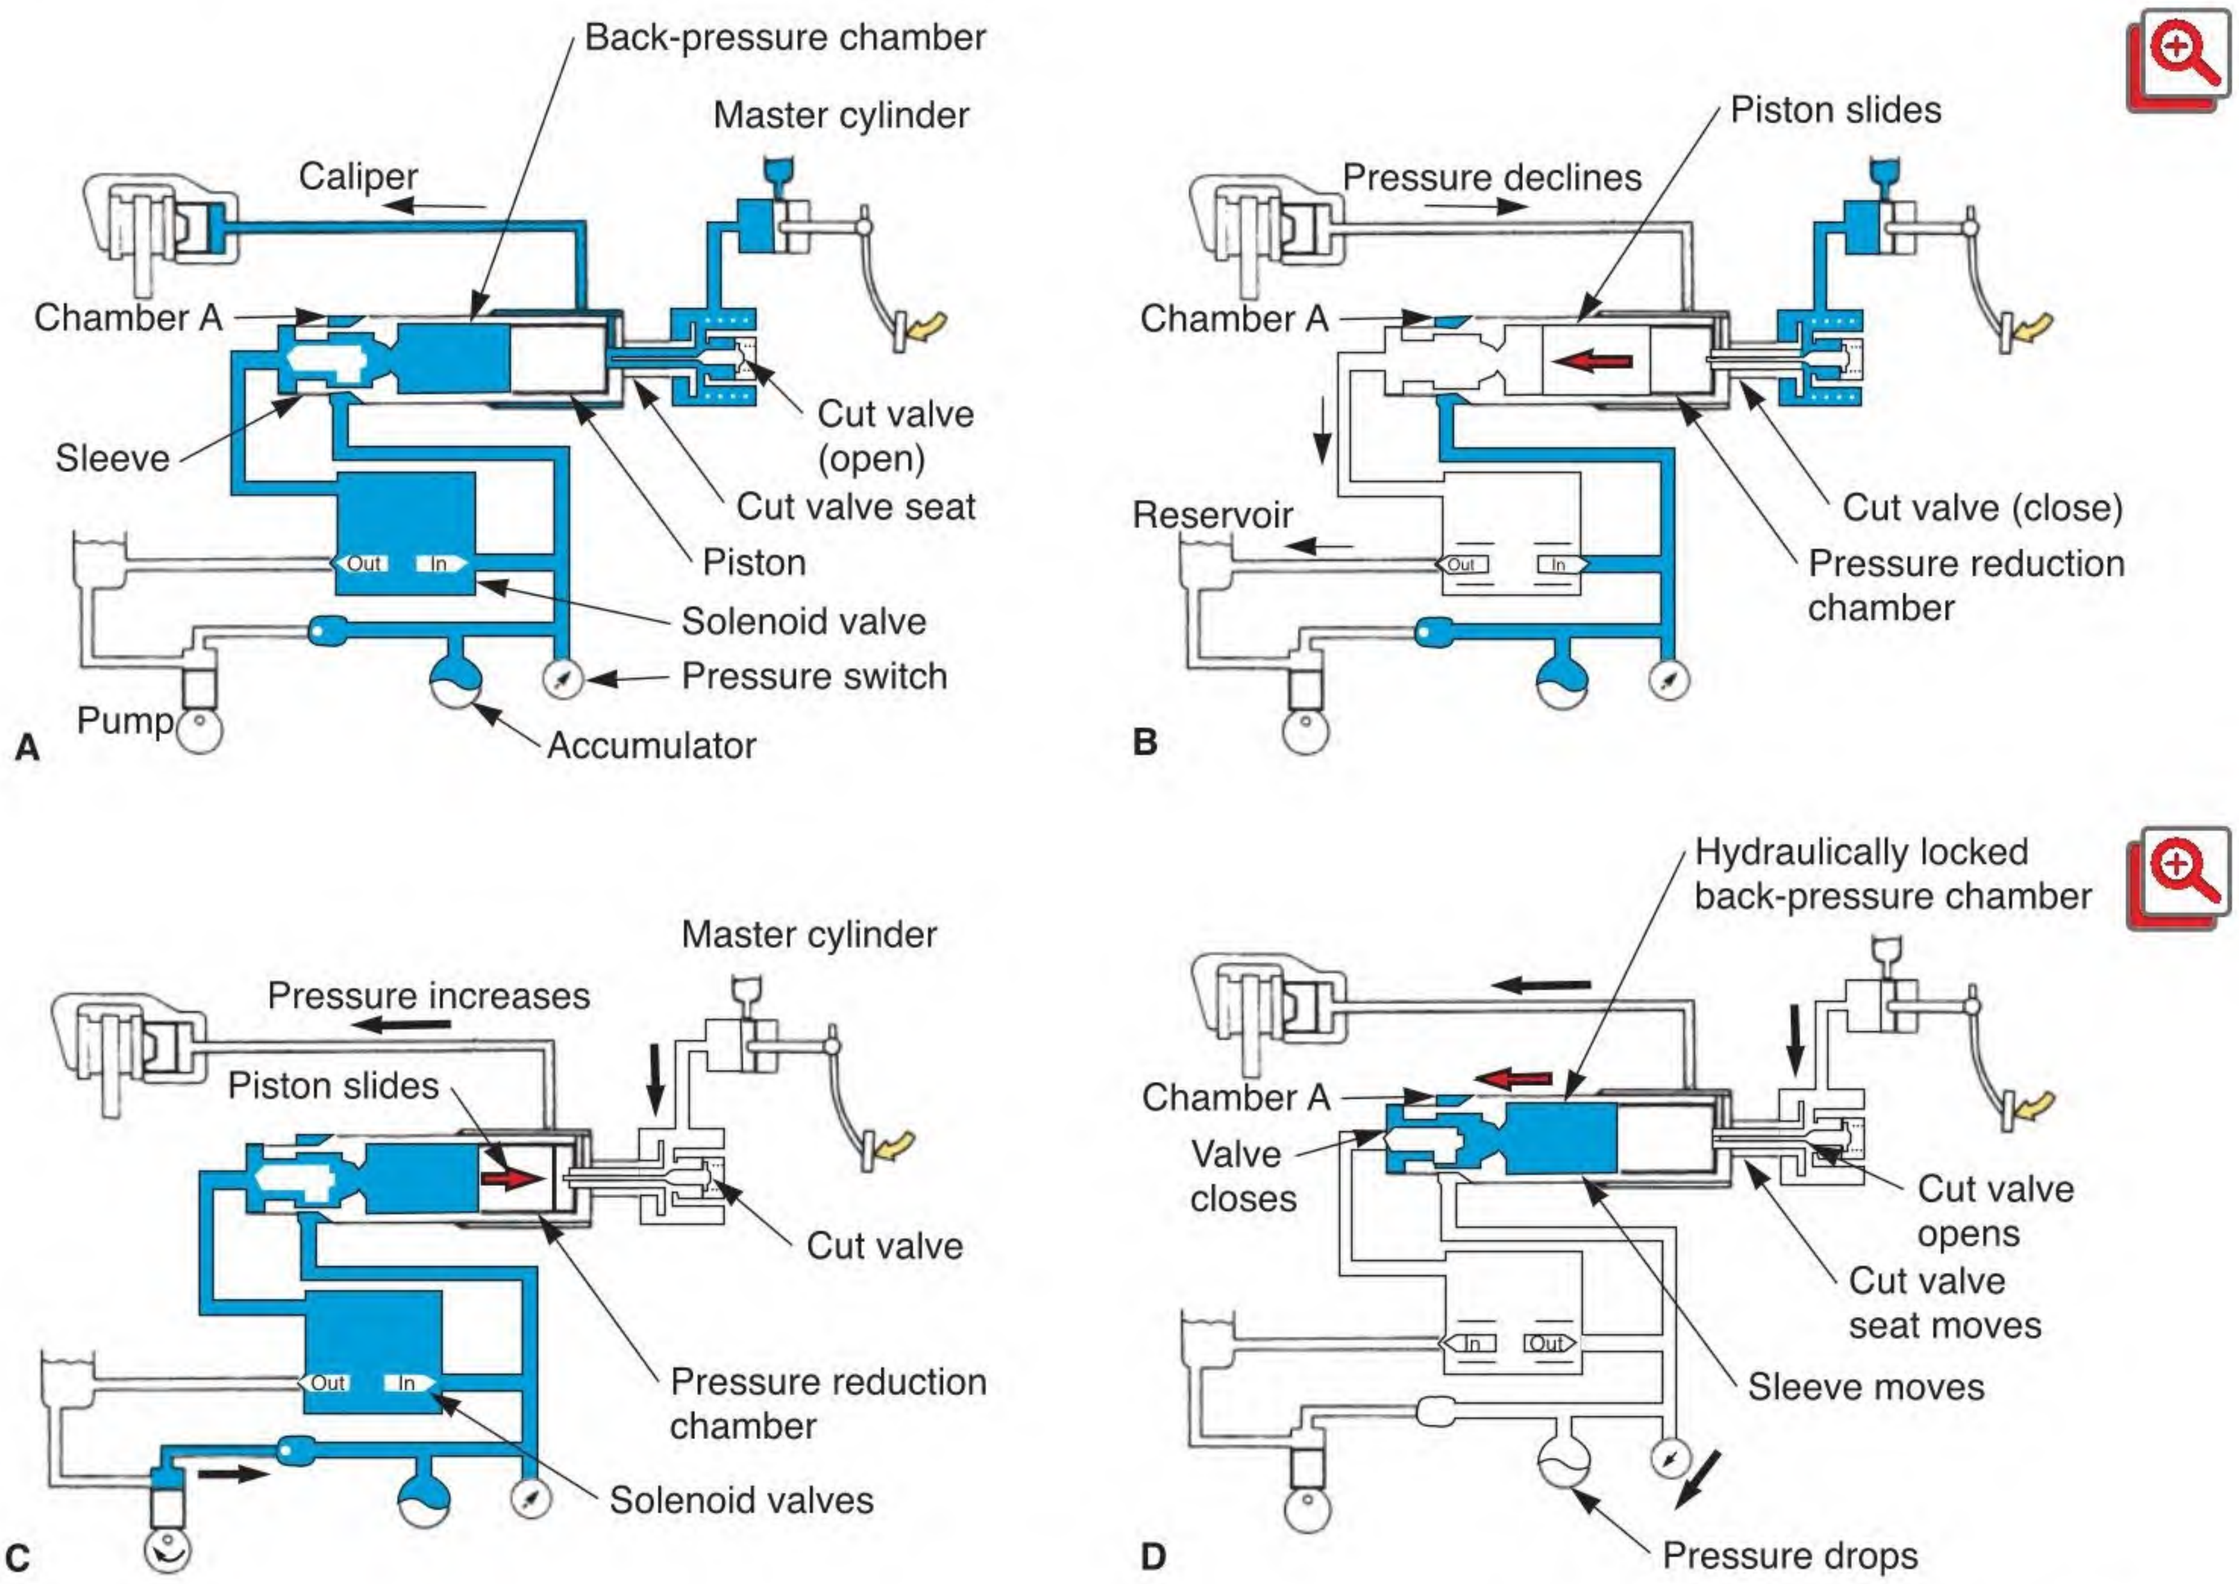
ABS Operation

Under normal braking conditions, ABS is not used. The master cylinder reacts to brake pedal movement. It sends fluid pressure to each wheel cylinder without ABS intervention. A proportioning valve, like the one found in conventional braking systems, is commonly used to reduce pressure to the rear brakes.

If the brakes are applied in a panic stop and a wheel begins to lock up, the ABS is activated. The wheel sensor on the slowing wheel instantly reduces the frequency of the ac signal sent to the ABS control module. The control module detects that the wheel is slowing down more than the others and is getting ready to slide or skid. The module then sends an electrical current to the correct solenoid on the electro-hydraulic modulator assembly to bleed pressure from that channel.

With many designs, when current is sent to the solenoid, the solenoid opens a valve to reduce the pressure to the brake cylinder with the slowing wheel. The ABS control module quickly cycles the current to the solenoid on and off, artificially "pumping the brakes" to keep the tire from skidding and losing traction.

When ABS takes over, the brake pedal will usually rise or drop and vibrate slightly. This is due to the pressure entering the system from the accumulator or pump and from the cycling of the solenoid valves. This is normal and will stop when ABS is no longer functioning.



When hydraulic pressure in the system drops below a specific point, the pressure switch closes and energizes the electric motor. This drives the pump to build pressure back up. Once pressure is normal, the pressure switch opens and the motor and pump shut off.

If an ABS component malfunctions, the ABS control module will detect an abnormal condition. It will then light the ABS warning light in the dash and deactivate the ABS. The brake system will still function normally, but without the anti-lock feature. The operation of an anti-lock brake system is shown in **Figure 82-10**.

Tech Tip

Warn new drivers that they should not pump the brake pedal on a vehicle equipped with ABS. This can prevent the system from functioning. Instruct them to apply hard, steady pedal pressure so that the ABS can modulate, or "pump," the brakes. For the experienced driver, this can take time to learn.

Copyright Goodheart-Willcox Co., Inc.

Honda

Figure 82-10. Study the operation of an anti-lock brake system. A—ABS is not functioning. Master cylinder pressure flows to the caliper normally. B—ABS starts working to avoid a skid. The system operates the solenoid valve to close the inlet valve and open the outlet valve. High pressure is released to the reservoir. This reduces pressure to caliper, allowing that wheel to turn and not skid. C—ABS increases caliper pressure to maintain stopping action. The solenoid inlet valve is opened and the outlet valve is closed. High-pressure brake fluid is then sent to the back-pressure chamber and the piston slides to increase pressure to brake caliper. D—The ABS control unit monitors pressure in the high-pressure passage by means of a pressure switch. The control unit turns on the ABS warning light. The sleeve moves and hydraulically locks the back-pressure chamber. This connects the master cylinder to the caliper for normal braking again.

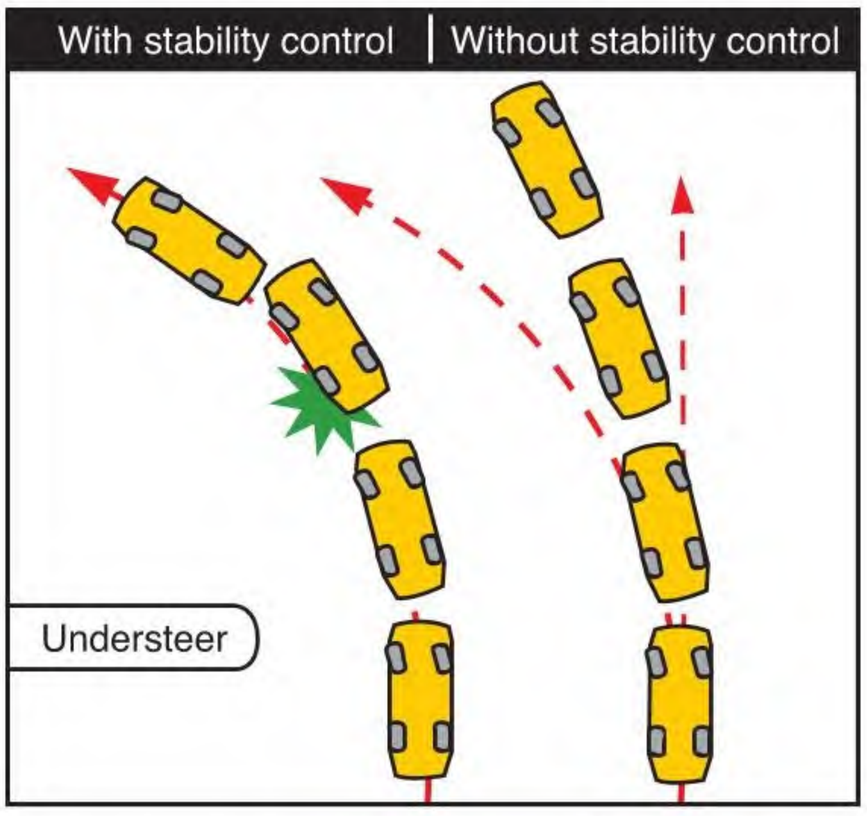
Traction and Stability Control Systems

As mentioned, traction control systems are designed to prevent the vehicle's wheels from spinning and losing traction under hard acceleration. Most traction control systems work with the anti-lock brake system to cycle hydraulic pressure to the wheel spinning the fastest. The control module is capable of applying one wheel brake at a time. Some systems also reduce engine power output to reduce skidding.

An indicator light comes on anytime the traction control system is activated. This warns the driver that the tires are losing traction and slipping on the road surface. He or she then knows that the traction control system is trying to limit or prevent this problem.

A stability control system is an advanced system that reduces tire spin upon acceleration and prevents tire skid when cornering too quickly. This system uses more input signals from various sensors to provide greater control over vehicle handling under severe cornering, braking, and acceleration conditions. It is designed to make the vehicle more stable under

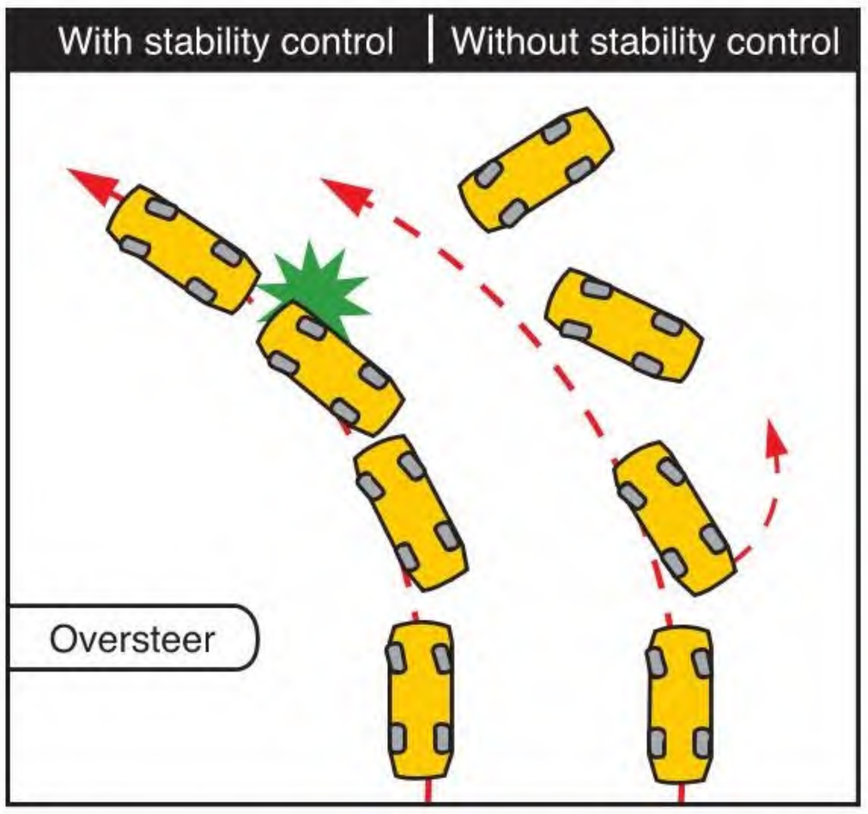
Copyright Goodheart-Willcox Co., Inc.



emergency handling situations, such as when trying to avoid a collision.

If ***understeer*** is detected (front tires lose adhesion with the road in a turn), the control module will apply braking force to the inside rear wheel. This will help bring the front of the vehicle back under control for making the turn. See **Figure 82-11**.

If the stability control system detects ***oversteer*** (rear tires lose adhesion with the road surface and slide sideways), additional braking force is automatically applied to the outside front wheel. This helps correct the oversteer so the rear of the vehicle does not spin out or slide sideways in a sharp turn. Refer to **Figure 82-12**.



In addition to the wheel speed sensors, a stability control system may use inputs from the following sensors:

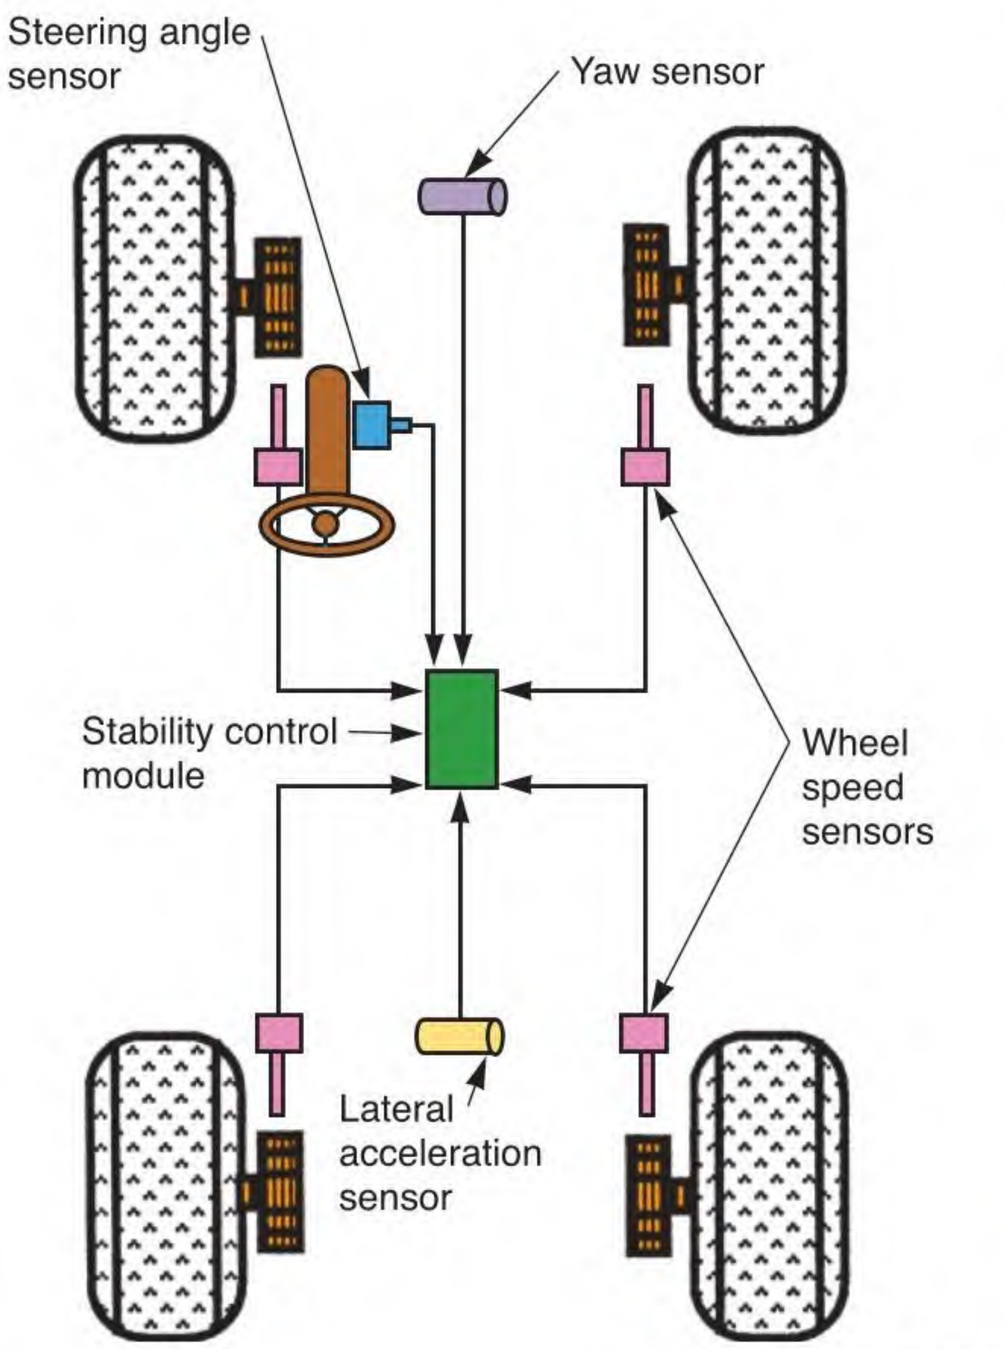
- ***Steering angle sensor***—The steering angle sensor measures how sharply the steering wheel is rotated to the right or left.
- ***Lateral acceleration sensor***—The lateral acceleration sensor measures how much side force is generated by a turn.
- ***Yaw sensor***—This sensor measures the direction of the thrust generated by vehicle movement.
- ***Throttle position sensor***—The throttle position sensor measures how far the driver has pressed down on the accelerator to control engine power output.
- ***Brake pressure sensor***—This sensor measures the amount of hydraulic pressure produced by the driver pressing on the brake pedal.

Goodheart-Willcox Publisher

Figure 82-11. With an understeer problem, the stability control system might apply the left rear brake to keep the front of the vehicle from sliding or drifting to the right in a left-hand turn.

Goodheart-Willcox Publisher

Figure 82-12. With an oversteer problem, the stability control system can apply the right front brake to keep the rear of the vehicle from sliding around in a left-hand turn.



- ***Other sensors***—These sensors give the control module information about the driver's actions and the resulting vehicle motion.

These sensors help the control module determine if the vehicle is skidding out of control, so corrective action can be taken. The control module is programmed to know when the vehicle is near its maximum rate of directional change. If this limit is reached, the system activates, **Figure 82-13**.

The control module is preprogrammed to apply one or more of the wheel brakes. It can also decrease or increase engine power to maintain vehicle control. If the driver rotates the steering wheel hard right for a sharp turn, the steering angle sensor signals the stability control module. The control module calculates how fast each wheel should be turning. The inside wheels should be spinning more slowly than the outside wheels because they are traveling less distance in the turn.

For example, the control module can use sensor signals to determine if the vehicle is following its intended direction of travel. The module calculates the frequency that each speed sensor should produce as the steering wheel is turned. If one or more of the wheels are not spinning at the right speed (skidding on road surface), the control module can react within 40 milliseconds to take corrective action. It might cut engine power slightly and apply one of the wheel brake calipers to reduce skidding.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 82-13. Note the extra sensors that are used in a stability control system.

Tech Tip

When driving a vehicle equipped with a stability control system, a common mistake is to try to counter-steer the vehicle out of a skid when turning. This often causes overcorrection. It is best to continue steering in the desired direction of travel, allowing the system to correct the skid. This is similar to getting used to driving a vehicle with anti-lock brakes.

ABS Service

Before servicing an anti-lock brake system, you should be familiar with how a normally operating system works and feels. Become familiar with the pedal pulsations that occur when the ABS is activated. Test-drive known good vehicles with the same type of ABS. Memorize how the pedal bumps when ABS is first activated and how it vibrates as the system modulates. This will let you quickly detect some problems because you will know when the system in question does not "feel right."

You should also be familiar with the exact type of ABS being repaired. Since designs and repair procedures vary, read the service manual for the vehicle at hand. This will give you the information needed (diagnosis charts, part locations, specifications, procedures, etc.) to perform competent repair work.

Warning

ABS systems can retain high hydraulic pressure even when the vehicle is shut off. To prevent injury, you must relieve this pressure before disconnecting any part of the hydraulic system! Many manufacturers recommend pumping the brake pedal a minimum of 40 times with the ignition key in the off position to release the pressure. Other manufacturers require the use of a dedicated tool to relieve system pressure. Refer to the service manual for factory recommended procedures.

ABS Inspection

To begin anti-lock brake system diagnosis, make a visual inspection of all the major parts. Look for obvious problems that could affect braking action. In addition to inspecting for conventional troubles, check for the following:

- ABS indicator light on.
- Low or contaminated brake fluid.
- Brake fluid leaks, especially at the modulator seals, gaskets, and lines.
- Worn or damaged brake pad linings and rotors.
- Tires that will not rotate freely.
- Loose or worn wheel bearings, which could affect wheel speed sensor operation.
- Badly worn tires or tires of unequal size, which could upset ABS operation.
- Damaged or improperly mounted speed sensors and trigger wheels.

Based on your findings, determine what step should be taken next. If the fluid level is low, check more closely for leaks. If one set of brake pads is worn down, make sure that the corresponding wheel is not dragging. Use common sense and your knowledge of ABS operation to help find the source of the trouble.

Copyright Goodheart-Willcox Co., Inc.

Scanning ABS

Late-model anti-lock brake systems have very sophisticated on-board diagnostics. Manufacturers have developed these elaborate self-test capabilities so the technician can troubleshoot and repair ABS with minimum difficulty. A typical ABS diagnostic system can produce over 50 trouble codes to help you find the cause of a malfunction.

When the ignition key is turned, an ABS warning light should glow for several seconds after the vehicle is started and then go off. This lets you know that the system is armed and functioning.

If the ABS light stays on, the ABS control module has detected an abnormal operating condition. This would signal you to use a scan tool to analyze the system and read trouble codes.

On some older vehicles, manufacturers may have specialized testers, or scanners, for their anti-lock brake systems. Follow the operating and service manual instructions when using these tools.

First, use the scan tool to check for a ***code history*** (list of stored codes with the number of times each has occurred). This will let you know how often the problem occurs. It will also let you determine how many different codes have been set in the past.

Next, review all the trouble codes. This may help you quickly find the bad ABS component or circuit. Trouble codes are provided for all major electrical-electronic parts in the system. The scan tool will normally indicate problems with the following:

- Wheel speed sensor circuits.
- ABS warning light circuit.
- System relays.
- Low system voltage.
- Modulator motors.
- Solenoid circuits.
- Brake switch circuit.
- Calibration memory in the ABS control module.
- Other circuits and components.

With many late-model anti-lock brake systems, the scan tool can be used to perform several manual and automatic tests. You can use the scan tool to manually control motors, relays, solenoids, and other ABS parts. The automatic tests are used to check the operation of the modulator. This will let you make sure every part is functioning properly.

You can also use the scan tool to obtain system values (voltage, current, resistance). However, this is only done when a problem is difficult to locate. You can check to see if any value is almost out of specification, but not tripping a trouble code. This will narrow down your diagnosis on "borderline" circuits and components that are causing intermittent problems.

ABS Pinpoint Tests

If your scan tool indicates a malfunction, you must still use pinpoint tests to determine the exact source of the problem. Use a multimeter to check the circuit or component. Compare your meter readings to factory specifications to verify the trouble.

The service manual will give electrical values for all major ABS circuits and components. One example is given in **Figure 82-14**.

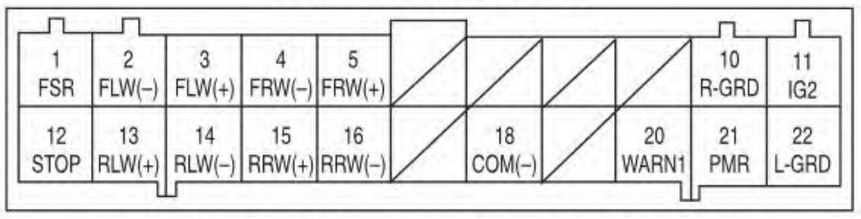
ABS Speed Sensor Service

If your scan tool points to a problem with a wheel speed sensor, make sure the sensor is mounted securely. Check that all wire connectors are tight. Also check for chipped or broken trigger wheel teeth. Road debris and improper repair methods can damage the trigger wheel.

If applicable, check the air gap between the speed sensor and its trigger wheel. Use a nonmetal feeler gauge of the specified thickness. See **Figure 82-15**.

A handheld scope will let you check the exact signal output from a suspicious wheel speed sensor. Unplug the wiring to the sensor and connect the scope to the sensor's output leads. To generate a waveform, spin the wheel by hand. Compare the actual sensor waveform to a known good waveform, **Figure 82-16**.

Tech Tip



If a pinpoint test of a wheel speed sensor shows no problem but the scan tool indicates a problem, check the wiring between the sensor and the ABS control module. If the wiring is not faulty, suspect the control module.

If the sensor is bad, replace it. Small bolts usually secure the sensor to the suspension knuckle. Clips may be used to secure the sensor wire to the body to prevent wiring damage, **Figure 82-17**.

After installing the new wheel speed sensor, adjust its air gap, if needed, using a brass or plastic feeler gauge. Speed sensor trigger wheels often require major part removal for service.

Honda

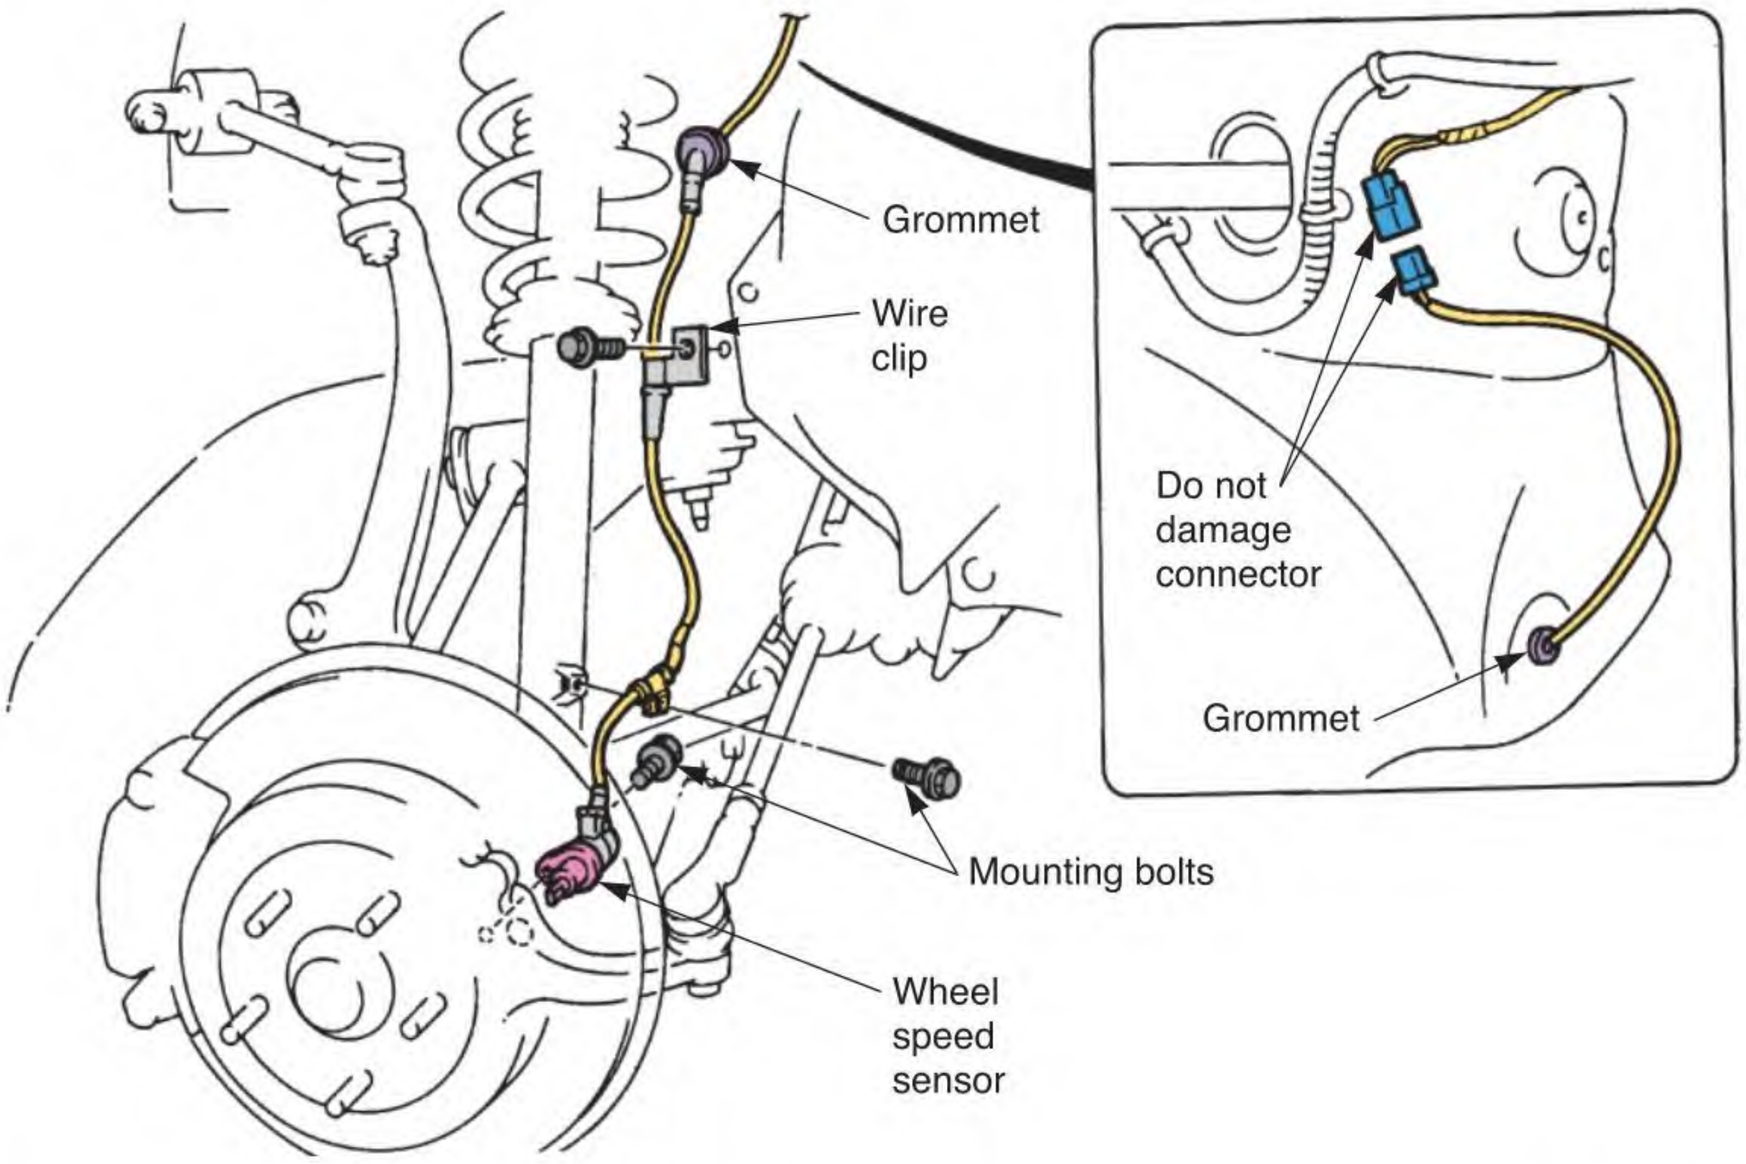
Figure 82-15. Some wheel speed sensors require adjustment of the air gap. The correct size nonmetallic feeler gauge should fit snugly between the sensor tip and the trigger wheel tooth.

Fluke

Figure 82-16. A handheld scope will measure the signal leaving a wheel speed sensor. A—Typical sensor hookup. B—Output signal from a speed sensor. The output should match the reading from the scan tool. If not, a wiring or control module problem is indicated.

Tech Tip

When working on anti-lock brakes, be careful not to damage the wheel speed sensor trigger wheels. When pulling off calipers, axles, and related parts, it is easy to hit and chip one or more of the small teeth on the trigger wheel. When the vehicle is driven again, this would activate a trouble code and require trigger wheel replacement.



ABS Modulator Check

Service Procedure

Most ABS modulator problems will show up when scanning. However, some automakers allow you to check the modulator in the following manner.

1. Place the vehicle on jack stands so all four tires are equally off the ground, **Figure 82-18A**.
2. Release the parking brake.
3. Rotate each wheel by hand. Make sure none of the wheels are dragging. A dragging wheel indicates that the system might not be releasing hydraulic pressure normally. Brake drag can also be caused by a frozen wheel cylinder, a restricted brake line or hose, and similar sources discussed in the previous chapter.
4. Connect a jumper wire to the correct terminals on the vehicle's diagnostic connector or use the scan tool to energize the modulator to apply hydraulic pressure to one of the wheels, **Figure 82-18B**.
5. Press down and hold the brake pedal while you have a helper make sure that the wheel will not rotate.
6. Using service manual instructions, energize the modulator to dump pressure to the wheel. Make sure the modulator relieves pressure from the wheel cylinder so the tire will rotate freely, **Figure 82-18C**.
7. Repeat steps 4–6 on the other wheels.

Copyright Goodheart-Willcox Co., Inc.

Mazda

Figure 82-17. When replacing a wheel speed sensor, do not damage the electrical connectors and replace any clips that hold the wiring on the body.

This test will check the operation of the modulator, brake tubing, brake hoses, solenoids, relays, ECM, and other major parts. Remember, these are general procedures. Refer to the service manual and scan tool manual for specific instructions.

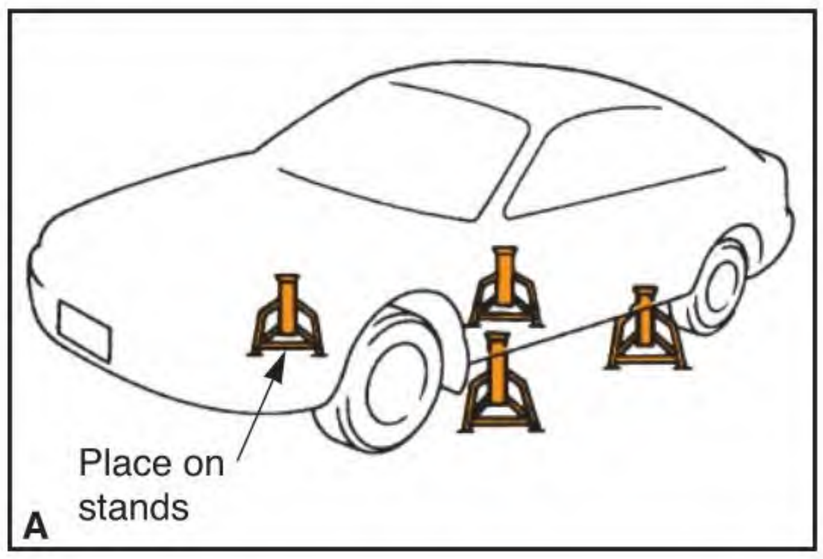
ABS Modulator Service

If the ABS modulator is faulty, most shops install a new or factory-rebuilt unit. Modulators are very complex and time-consuming to rebuild.

If the vehicle is under warranty, some dealerships repair or rebuild modulators in-house. Make sure the proper rebuild kit is available before starting. Also, compare cost of rebuilding the modulator to the cost of a new or factory rebuilt unit to determine the best course of action.

To remove an ABS modulator, disconnect all wires between the vehicle and unit. See **Figure 82-19**. Then, use a tubing wrench to loosen the brake lines going to the modulator. Remove the bolts that hold the modulator on its brackets. Then, lift the unit out of the engine compartment.

If you are installing a new or rebuilt unit, transfer any necessary parts from the old unit to the new one. These parts might include the combination valve, reservoir, master cylinder (integral units), and brackets. Coat O-ring seals with clean brake fluid to ensure a leakproof seal. Some units have numbered dip-switches (tiny lever switches) that must be set correctly for the make and model car.



General rules to keep in mind when repairing or replacing an ABS modulator include:

- Always install all parts included in the rebuild kit.
- If a new unit is being installed, make sure it has the correct part number.
- Always lubricate rubber parts with clean brake fluid of the appropriate type.
- Work on a clean, uncluttered workbench to avoid contamination.
- Avoid using compressed air on hydraulic parts. Oil from the compressor may deteriorate rubber parts.
- Prevent brake fluid from contacting electrical connections, painted surfaces, and electronic parts.
- Use correct torque values when tightening fasteners.
- Refer to the service manual for detailed procedures, specifications, and safety precautions.

Regenerative Braking Safety

When servicing regenerative braking systems on hybrid and all-electric drive trains, always keep the

Figure 82-18. Some automakers recommend testing an ABS modulator by energizing the unit and rotating each tire by hand. A—Place the vehicle in level position on jack stands. B—Energize the modulator to free or lock up each wheel as directed in the service manual. C—Rotate each tire by hand to make sure the modulator frees and holds the brake as designed.

12-volt and HV battery disconnected from the ABS control circuit. Pull out the HV battery disconnect; disconnect the 12-volt battery negative cable; and pull off the ABS control module connector, and remove related fuses or circuit breakers to keep all sources of power from reaching the ABS control module.

If you accidentally reconnect battery power to the ABS control circuit, it might perform an automatic pressure test to check for brake fluid leakage. During a pressure test, the ABS pump motor applies full hydraulic pressure to all four brake calipers. If the computer control system performs a pressure test while brake parts are being serviced, high-pressure brake fluid will shoot out any disconnected line or blow out any piston not still over its brake disc. Your fingers could be crushed if the hydraulic piston shoots from its bore at full brake line pressure!

ABS Bleeding

Bleeding an anti-lock brake system of air bubbles can be similar to bleeding conventional brakes or it might require special procedures and tools.

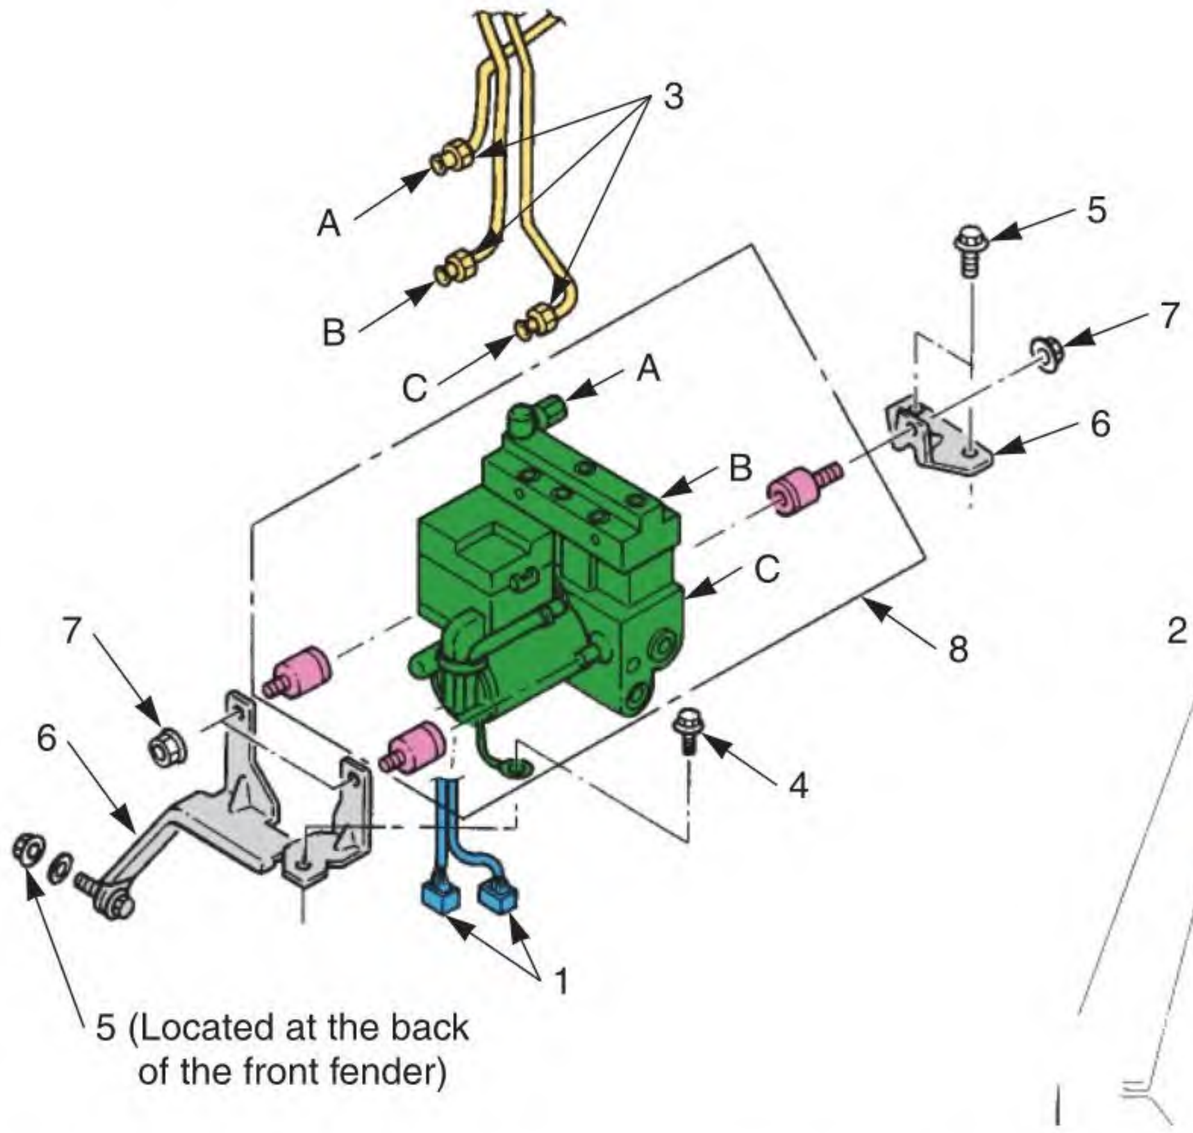
When servicing a master cylinder that is separate from the modulator, plug the brake lines to keep out as much air as possible. Bench bleed the new master cylinder. Then, re-bleed the master cylinder at its lines once it is mounted on the vehicle.

When the master cylinder is formed as an integral part of the modulator, you may need to use a very specific bleeding procedure. An electrical break-out box and an electronic unit might be required to properly energize the solenoids when bleeding some systems. Refer to the service manual when in doubt. See **Figure 82-20**.

ABS Wet Pavement Test

Warning

When test-driving a vehicle that has a malfunctioning or newly repaired ABS, drive slowly and stay out of traffic. Make sure you have adequate braking action before driving on public streets.



A ***wet pavement test*** can be done to check your repair work or to help pinpoint a problem when all other methods of diagnosis have been exhausted. It verifies the operation of the ABS electronics, as well as all mechanical parts associated with normal braking.

The wet pavement test is performed with two tires on wet pavement and the other two tires on dry pavement. Make sure the vehicle has enough stopping power before testing.

Use a garden hose to wet a small strip of pavement about a foot wide and 20 feet long in an open parking lot. Make sure the lot is large enough to provide ample stopping room if the brakes fail to work normally.

Position the vehicle so that only the right or left tires ride on the wet area. Drive the vehicle across the strip of wet pavement at about five miles per hour. Then, hit the brakes hard to try to make the tires skid on the pavement. Ask a helper to watch the tire contact on the wet pavement and to let you know if either

tire is totally locking up or not modulating upon hard brake application. This will let you determine if any wheel is not being controlled by the ABS.

As you brake and two of the tires try to skid, you should feel the pedal modulate. The helper should not see the tires lock up or continue to rotate freely. The ABS system should modulate hydraulic pressure so the tires almost skid.

Repeat this test with the other set of tires on the wet strip of pavement. This will allow you to check modulation on all four wheels.

This test will provide you with useful information about the condition and operation of the ABS. Make sure the ABS indicator light stays off before releasing the vehicle to the customer.

Traction and Stability Control System Service

The diagnosis and repair procedures for traction and stability control systems are similar to the methods described for ABS. You would use an initial inspection and your scan tool to find any obvious problems or trouble codes. If you have trouble codes, use pinpoint tests to verify the problem. After repairs are made, re-scan the system to check your work.

If needed, test-drive the vehicle while scanning to check the action of the traction control system. This should be done in your shop's parking lot or somewhere away from pedestrians and traffic. A gravel surface or wet pavement is best because you can intentionally make the vehicle try to skid upon acceleration. If needed, use a garden hose to wet down an area in your parking lot.

Copyright Goodheart-Willcox Co., Inc.

When on the slick surface, accelerate the vehicle and try to make the drive tires spin. This should activate the traction control or stability control system. You can then use scanner data about the wheel speed sensors, hydraulic unit, engine control module (ECM), and other components to help isolate the problem.

Tech Tip

When the traction control or stability control system energizes, the indicator light should come on and you should usually hear a rapid buzzing or clicking sound from the modulator.

Final System Check

Before releasing a vehicle after ABS, traction control, or stability control system repairs, you should:

- Clear trouble codes and re-scan the system for problems.
- Check the brake fluid level in the system.
- Test-drive the vehicle in an area without traffic.
- Simulate a panic stop several times in a large parking lot.
- Make sure the ABS indicator light stays off.

Diagnostic Case Study

Concern: Mrs. Peterson brings her 2013 Chevrolet Cruze to the shop. She says that her ABS warning light is glowing, but the brakes still seem to be working normally.

Cause: Duff test-drives the vehicle to verify the problem. As Mrs. Peterson explained, the ABS light stays on after the car is started, but the brakes seem to be working properly. Duff connects a scan tool to the vehicle. The trouble code retrieved (DTC C1175) indicates a problem with the speed sensor circuit at the left-rear wheel. Duff turns the repair over to one of the shop's brake technicians.

The technician removes the left-rear wheel to gain access to the sensor. The wires are still connected to the sensor and appear to be in good condition. The technician disconnects the sensor from the harness and uses a scope to check the sensor's output as the hub is rotated. The waveform produced by the sensor is erratic, indicating a problem with the sensor itself or the trigger wheel. Since the sensor and trigger wheel are integral parts of the hub assembly, the technician must replace the entire assembly.

Correction: The technician removes the brake drum and the hub assembly. He installs the new hub assembly and reassembles the other parts in the reverse order of disassembly. After a test-drive to ensure the car's problem has been corrected, the technician releases the vehicle to its owner.

Summary

- ABS uses wheel speed sensors, an ABS control module (computer), an electro-hydraulic brake actuator, and conventional hydraulic brake circuits to prevent wheel lockup during hard braking.
- When the tires skid, they actually lose traction or friction with the road surface. This can increase stopping distance and reduce vehicle control in some situations.
- The wheel speed sensors produce ac signals that correspond to wheel and tire speed.
- The ABS control module is a small computer that uses wheel speed sensor inputs to control the operation of the electro-hydraulic modulator.
- The ABS electro-hydraulic modulator, also called an ABS actuator, regulates the fluid pressure applied to each wheel brake assembly during periods of hard braking.
- Hydraulic pressure modulation refers to the electro-hydraulic unit's ability to rapidly cycle pressure to the wheel cylinders or calipers on and off, preventing wheel lockup and skidding.
- An integrated ABS combines the power booster, master cylinder, and modulator units into one assembly. All these units are mounted together.
- In a nonintegrated ABS, the major units are separated. A conventional booster and master cylinder are used with a separate electro-hydraulic modulator.
- In the dump mode, the ABS releases hydraulic pressure to one or more of the brake wheel cylinders or calipers.
- In the reapply mode, the ABS applies hydraulic pressure to one or more of the wheel brake assemblies.
- A four-channel ABS has a separate hydraulic control circuit for each wheel.

Copyright Goodheart-Willcox Co., Inc.

- Traction control systems are designed to prevent the vehicle's wheels from spinning and losing traction under hard acceleration.
- A stability control system is an advanced system that reduces tire spin upon acceleration and prevents tire skid when cornering too quickly.
- You should also be familiar with the exact type of ABS being repaired. Since designs and repair procedures vary, read the service manual for the vehicle at hand.
- To begin anti-lock brake system diagnosis, make a visual inspection of all the major parts.
- Late-model anti-lock brake systems have very sophisticated on-board diagnostics.
- If the ABS light stays on, the ABS control module has detected an abnormal operating condition.
- With many late-model anti-lock brake systems, the scan tool can be used to perform several manual and automatic tests.
- If your scan tool indicates a malfunction, you must still use pinpoint tests to determine the exact source of the problem.
- If applicable, check the air gap between the speed sensor and its trigger wheel. Use a non-metal feeler gauge of the specified thickness.
- Most ABS modulator problems will show up when scanning. However, some automakers allow you to check the modulator by rotating each wheel by hand while energizing the unit.
- If the ABS modulator is faulty, most shops install a new or factory-rebuilt unit. Modulators are very complex and time-consuming to rebuild.
- Bleeding an anti-lock brake system of air bubbles can be similar to bleeding conventional brakes or it might require special procedures and tools.
- The wet pavement test is performed with two tires on wet pavement and the other two tires on dry pavement.
- The diagnosis and repair procedures for traction control systems are similar to the methods described for ABS.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

ABS
ABS actuator
ABS control module
ABS electro-hydraulic modulator
ABS warning light
air gap
anti-lock brake systems
brake accumulator
brake fluid pump and motor
brake fluid reservoir
brake master cylinder-booster assembly
brake pressure sensor
brake pressure switch
brake solenoid valve block
channel
code history
dump mode
four-channel ABS
hydraulic pressure modulation
integrated ABS
isolation mode
lateral acceleration sensor
nonintegrated ABS
one-channel ABS
other sensors
oversteer
reapply mode
sensor rotor
stability control systems
steering angle sensor
throttle position sensor
traction control systems (TCS)
trigger wheel
two-channel ABS
understeer
wet pavement test
wheel speed sensors
yaw sensor

Activities

1. Inspect the ABS system on several different vehicles. Write down any problems you found on each. Also summarize any differences in part locations or part designs for a class discussion.
2. Scan a late-model ABS system. Unplug some of the wiring connectors in the system and note the scanner readout. Make a report of what you learned.

Review Questions

Answer the following questions using the information provided in this chapter.

1. A(n) _____ system prevents wheel lockup during hard braking.
2. What happens when a tire skids or slides during hard braking?
3. In addition to the brake warning light in the instrument cluster and the sensor trigger wheels, list and describe the four major parts of an anti-lock brake system.
4. In addition to reducing stopping distances, ABS improves driver and passenger safety by increasing _____ under panic stop conditions.
5. The wheel speed sensors produce ac _____ that correspond to wheel and tire speed.

Copyright Goodheart-Willcox Co., Inc.

6. What should a technician do before servicing a regenerative brake system on a hybrid or all-electric vehicle?
7. List and summarize the six major parts of an ABS modulator.
8. Describe the three operating modes of an ABS modulator.
9. Technician A says that most traction control systems work with the anti-lock brake system to cycle hydraulic pressure to the wheel spinning the fastest. Technician B says that stability control systems use more input signals from various sensors to provide greater control over vehicle handling under severe cornering, braking, and acceleration conditions. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. A scan tool is commonly used to troubleshoot a modern ABS. True or False?

ASE-Type Questions

1. For maximum stopping power with anti-lock brakes, you want the tires to:
   (A) skid until the vehicle stops.
   (B) almost, but not quite, skid.
   (C) lock up until the vehicle stops.
   (D) turn alternately left and right until vehicle stops.
2. Technician A says a scan tool will usually test the action of major ABS components by energizing them. Technician B says that a scan tool does not have this capability. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. A car enters the shop with the ABS light glowing. Technician A says to inspect the system for obvious troubles. Technician B says to also use a scan tool to help find the problem. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. All of the following sensors may send inputs to the vehicle's stability control system to determine vehicle skidding and body movement *except:*
   (A) throttle position sensor.
   (B) oxygen sensor.
   (C) brake pressure sensor.
   (D) yaw sensor.
5. Which of the following *cannot* be checked with a scan tool?
   (A) Trouble code history.
   (B) Present trouble codes.
   (C) Brake lining condition.
   (D) Wheel speed sensor circuits.
6. Technician A says that you must set the sensor air gap on some vehicles. Technician B says that the air gap between the sensor and trigger wheel needs to be increased each year the vehicle is in service. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. A scan tool shows a problem with the right front wheel speed sensor circuit. Technician A says that after servicing the sensor, the ABS control module must be reprogrammed. Technician B says to replace the brake master cylinder. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. A new ABS modulator is being installed on a vehicle. Technician A says you may have to transfer the old combination valve to the new unit. Technician B says to coat all rubber parts with clean brake fluid. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. A scan tool shows a problem with the modulator pump motor. Technician A says to check for power to the motor from the ABS control module. Technician B says if no power is reaching the motor to check the wiring between the control module and the motor. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. After completing repairs on a stability control system, you should do all of the following *except:*
   (A) clear trouble codes and re-scan for problems.
   (B) recheck brake fluid level in system.
   (C) test-drive the vehicle slowly in an area without traffic.
   (D) reprogram the control module.

Section 14

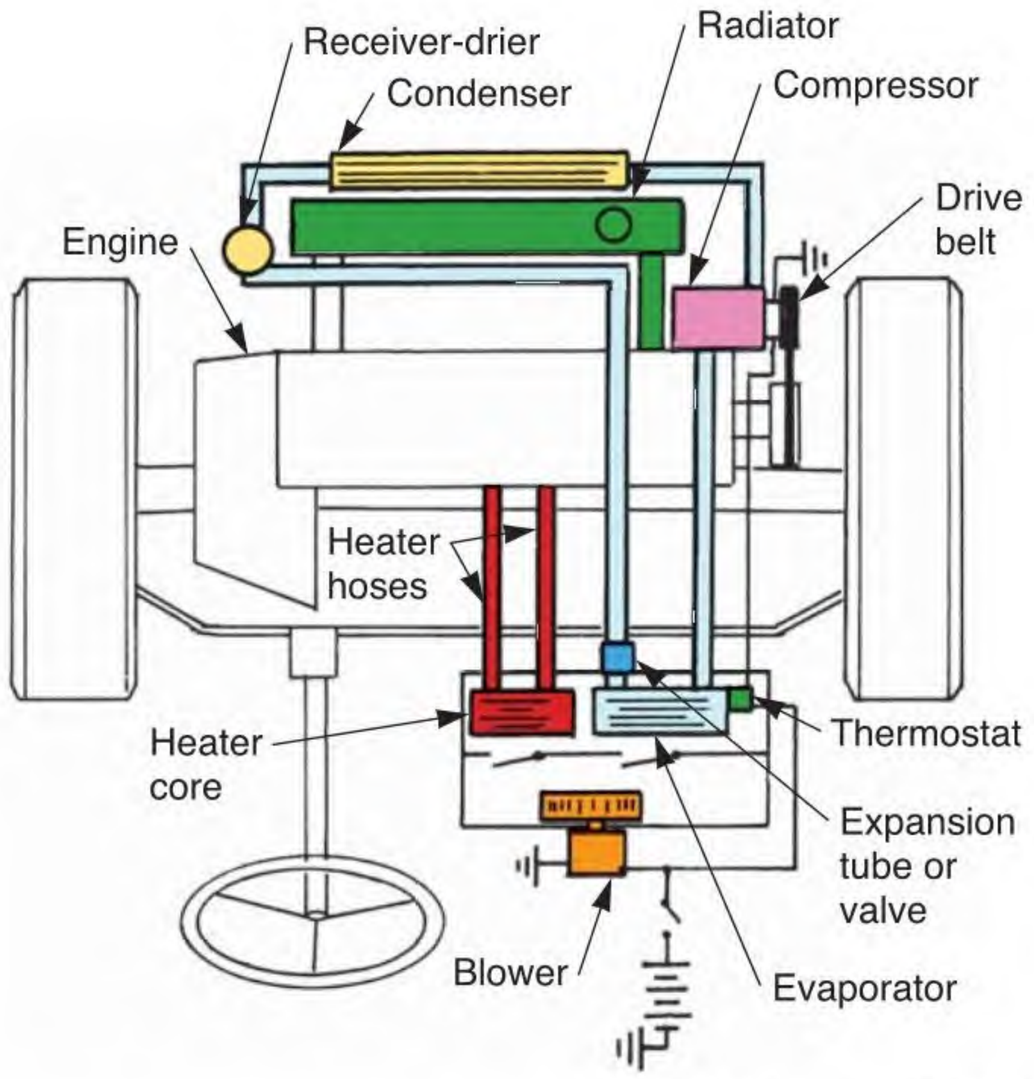
Heating and Air Conditioning Technology

Chapter 83
Heating and Air Conditioning Fundamentals

Chapter 84
Heating and Air Conditioning Diagnosis, Service, and Repair

To the vehicle owner, the heating and air conditioning systems are vital. On a cold winter morning or a hot summer day, these systems keep the passenger compartment comfortable for the vehicle's occupants. If the heating or air conditioning system is not working properly, the passenger compartment can become very unpleasant and so can the customer.

This section explains the operation, service, and repair of heating and air conditioning systems. It details state-of-the-art methods for repairing these systems without damaging our environment. It will also help you pass the ASE Test A7, *Heating and Air Conditioning*.



Chapter 83
Heating and Air Conditioning Fundamentals

After studying this chapter, you will be able to:

- Explain the principles of refrigeration.
- Describe the four cycles of refrigeration.
- Describe the high and low sides of an air conditioning system.
- Explain the basic function and construction of each major part of a typical heating and air conditioning system.
- Summarize the operation and interaction of heating, ventilation, and air conditioning systems.
- Describe safety precautions to be observed when working on heating and air conditioning systems.
- Correctly answer ASE certification test questions requiring a knowledge of modern heating and air conditioning systems.

The term "air conditioning" generally means to control the temperature, humidity, and flow of air in the passenger compartment of a vehicle. An automotive ***air conditioning system*** uses a refrigerant system, a heating system, and a ventilation system to provide a comfortable environment in all weather conditions, **Figure 83-1**.

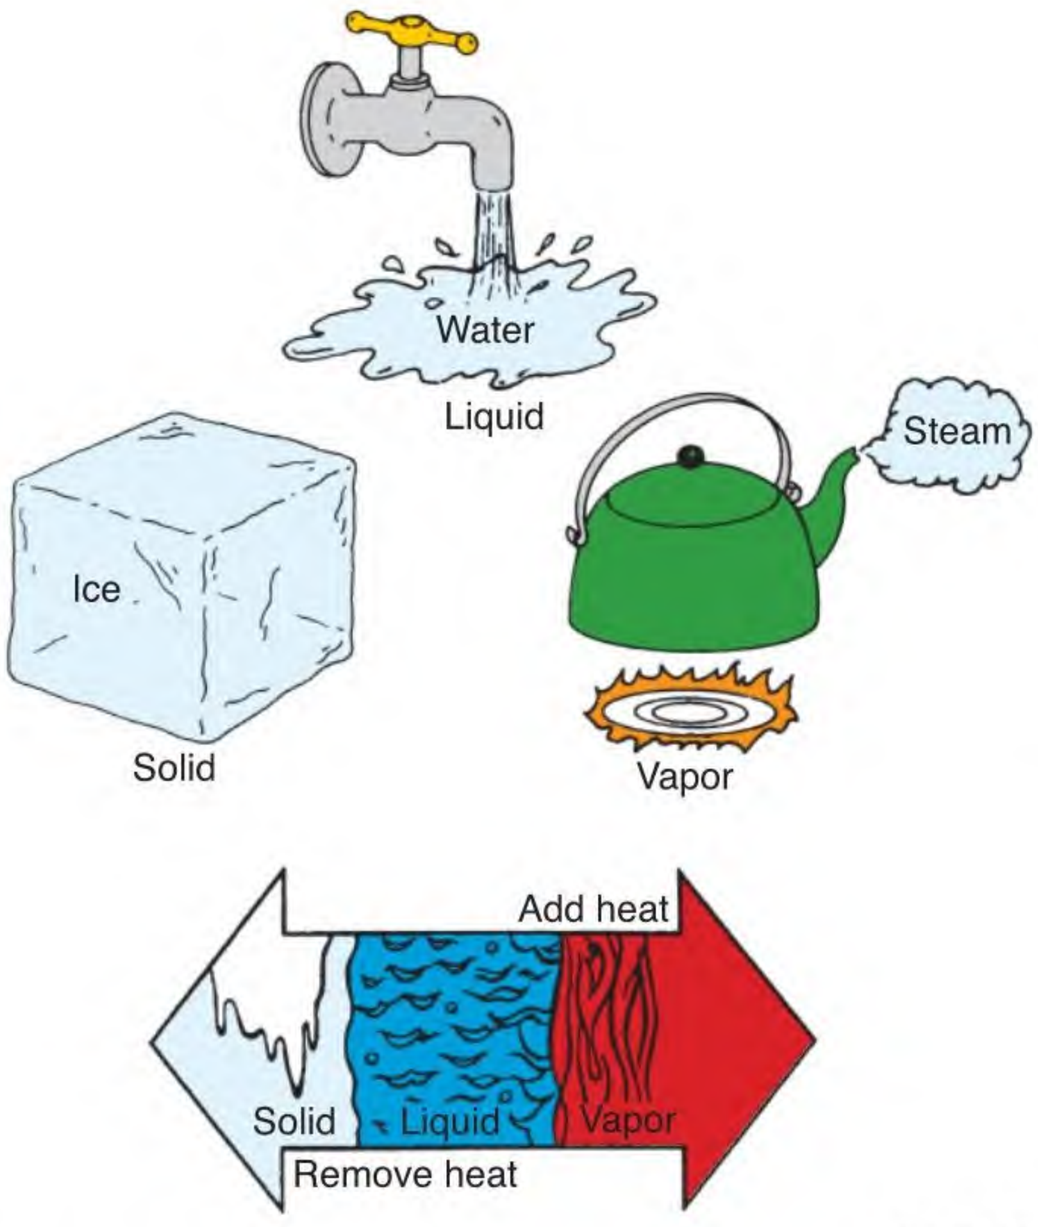
The ***refrigerant system*** uses a confined gas to provide cool, dehumidified (dried) air. The ***heating system*** uses heat from the engine cooling system to supply warm air. The ***ventilation system*** carries fresh outside air into the vehicle. These three systems work together to provide air conditioning.

Goodheart-Willcox Publisher

Figure 83-1. This top view shows the major parts of an air conditioning system. The heating, ventilation, and refrigerant systems work together to provide passenger comfort.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip



In the trade, the term "air conditioning" is often used to refer to the refrigerant system. Actually, this term refers to all three systems that help control the passenger compartment environment.

Principles of Refrigeration

An automotive refrigerant system (air conditioning) uses the same principles found in a home refrigerator. For this reason, you should understand a few rules that apply to refrigeration before studying actual automotive systems.

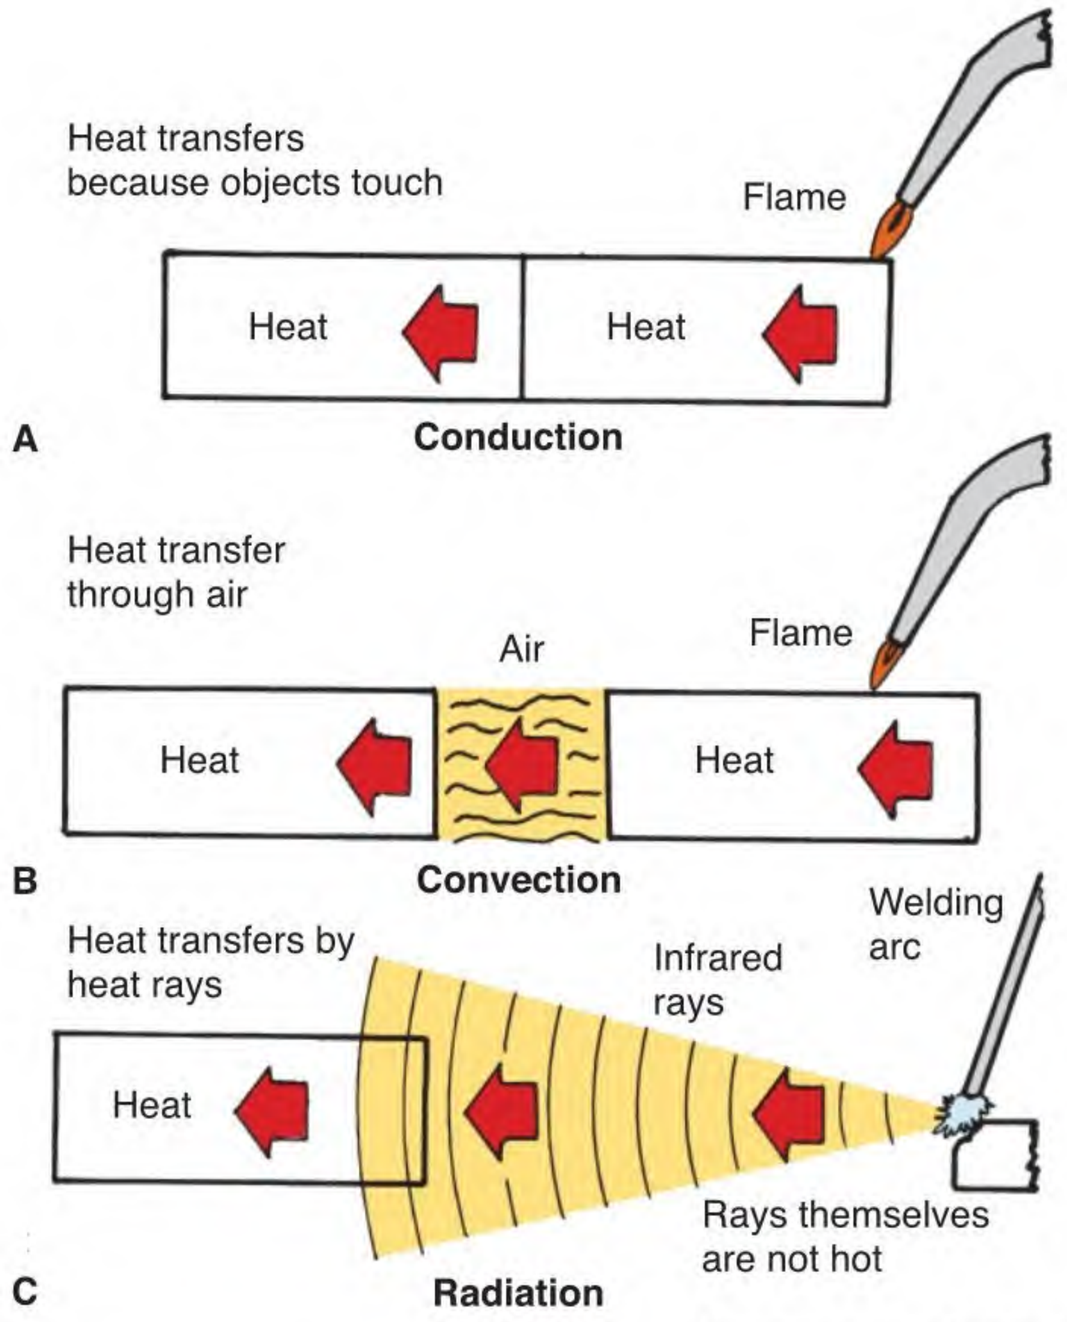
States of Matter

There are three basic ***states of matter***: vapor, liquid, and solid. For example, water can exist as a *vapor* (steam), a *liquid* (water), or a *solid* (ice). The temperature of the water controls its state. Look at **Figure 83-2**.

Deere & Co.

Figure 83-2. These are the three fundamental states of matter. As temperature changes, the state of matter changes.

Heat and Matter



As you can see with the three states of water, heat is a controlling factor in the state of matter. Heat causes increased molecular motion inside a substance. The hotter an object, the faster its molecules move. The colder an object, the slower its molecules move.

At room temperatures, hydrogen and oxygen molecules are fluid and form a liquid. When water is hot enough, its molecules move fast enough to separate, forming a vapor. When water is cold enough, the molecules move slowly enough to join and form a solid chunk of ice.

Methods of Heat Transfer

There are three methods of heat transfer: conduction, convection, and radiation.

Conduction is heat transfer through objects that are touching each other, **Figure 83-3A**. For example, engine combustion heat is conducted into the water jackets through the block and cylinder head. The metal parts of the engine carry or *conduct* heat.

Goodheart-Willcox Publisher

Figure 83-3. Three means of heat transfer: conduction, convection, and radiation.

Copyright Goodheart-Willcox Co., Inc.

Convection is heat transfer caused by the air surrounding objects. For instance, when air blows through a radiator, heat is convected into the air. Air is the medium of heat transfer, **Figure 83-3B**.

Radiation, the third method of heat transfer, is commonly carried out by infrared waves (rays from the sun, for example). See **Figure 83-3C**. When the sun shines through the windows of a vehicle, interior parts (seats, steering wheel) can become very hot because of heat radiation. Radiant energy moves through space in waves. When the waves strike a solid object, the energy is absorbed by the object. The internal energy in the object's molecules increases, and the temperature of the object rises.

Heat Movement

Heat is caused by rapid molecule movement or excitation. Heat energy always moves from a hotter object to a colder object. Technically, when you hold a piece of ice, the ice does not really cool your hand. Instead, it removes heat energy from your hand. This makes your hand feel cold.

Cold is an absence of heat. Hot and cold are relative (dependent on each other). When one object is colder than another, the colder object simply contains less heat.

Heat Measurement

The ***British thermal unit (Btu)*** is the unit of measure for heat transfer from one object to another. For example, when the temperature of one pound of water increases one degree Fahrenheit at sea level pressure, one Btu of heat has moved into the water. The cooling potential of home air conditioning units is normally rated in Btus.

Vaporization and Evaporation

Mentioned briefly, ***vaporization*** and ***evaporation*** generally refer to a liquid changing into a vapor (gas) state. For instance, boiling water changing into steam (vapor) demonstrates vaporization. Water slowly changing to a vapor while sitting in the hot sun is evaporation. Heat is *absorbed* by the liquid as it changes into a vapor.

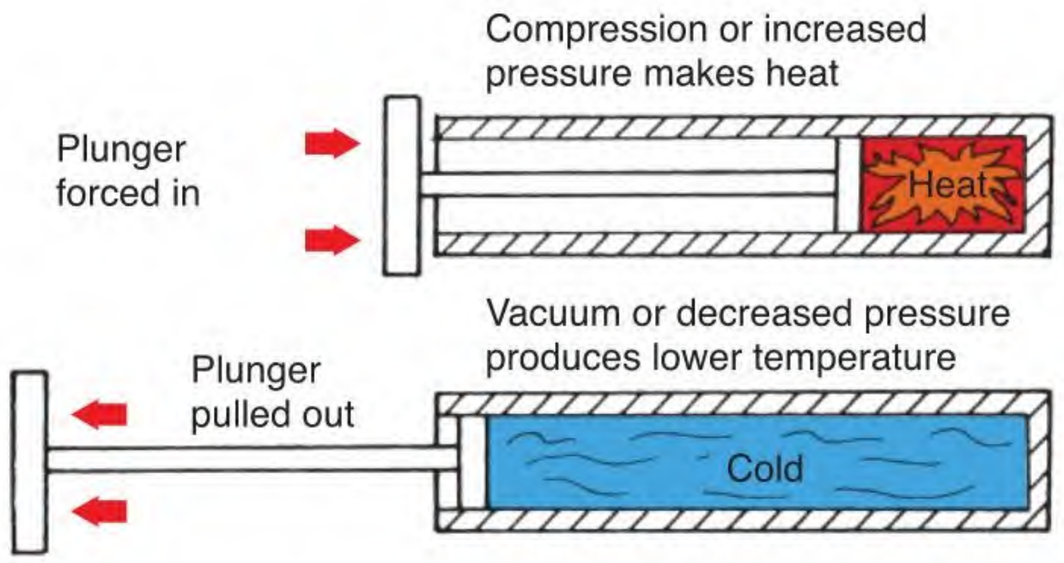
Condensation

Condensation occurs when a vapor changes back into a liquid (opposite of vaporization). For example, when water collects on the outside of a cold soft drink bottle on a warm day, moisture has condensed out of the air. Heat is *given off* when a vapor changes into a liquid.

Pressure and Temperature

When pressure is placed on a substance, the temperature of the substance increases—the substance gives off heat. When pressure is removed from a substance, the temperature of the substance drops. The substance absorbs heat (cools). Look at **Figure 83-4**.

Pressure also affects change of state. When a liquid is placed in a closed container and pressurized, its boiling (vaporizing) point increases. For example, the boiling point of water at sea level pressure (14.7 psi [101 kPa]) is 212°F (100°C). However, when the pressure is increased, water's boiling point increases. If pressure is decreased, the boiling point decreases. This principle is true for all substances.

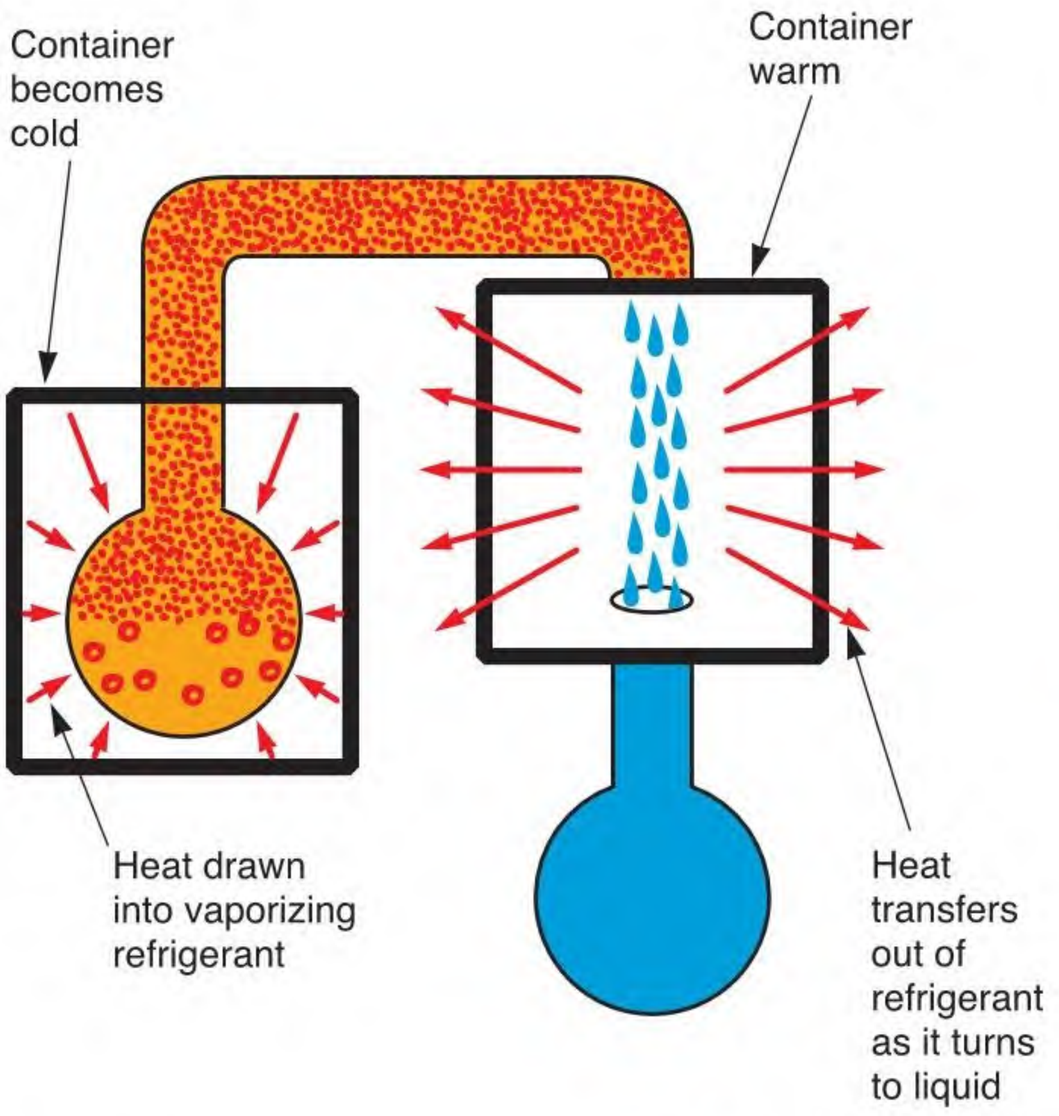


Refrigerant

A ***refrigerant*** is a substance with a very low boiling point. It is circulated through a refrigeration, or air conditioning, system. See **Figure 83-5**.

Refrigerant-12, also called ***R-12*** or ***Freon***, used to be the most common refrigerant. It has a boiling point of 22°F (–6°C) and vaporizes at room temperature and pressure. However, it was determined that R-12 is dangerous to the environment due to a chemical reaction with the atmosphere. R-12 has been phased out and newer vehicles no longer use this type refrigerant.

The ***R-134a*** refrigerant replaced R-12 because it is less damaging to the ozone layer around the earth. Newer cars, vans, and trucks are equipped with refrigerant systems that require the use of R-134a.



As discussed in the next chapter, several system parts, controls, sensors, tools, and procedures have changed with the newer, environmentally-safe refrigerant.

Goodheart-Willcox Publisher

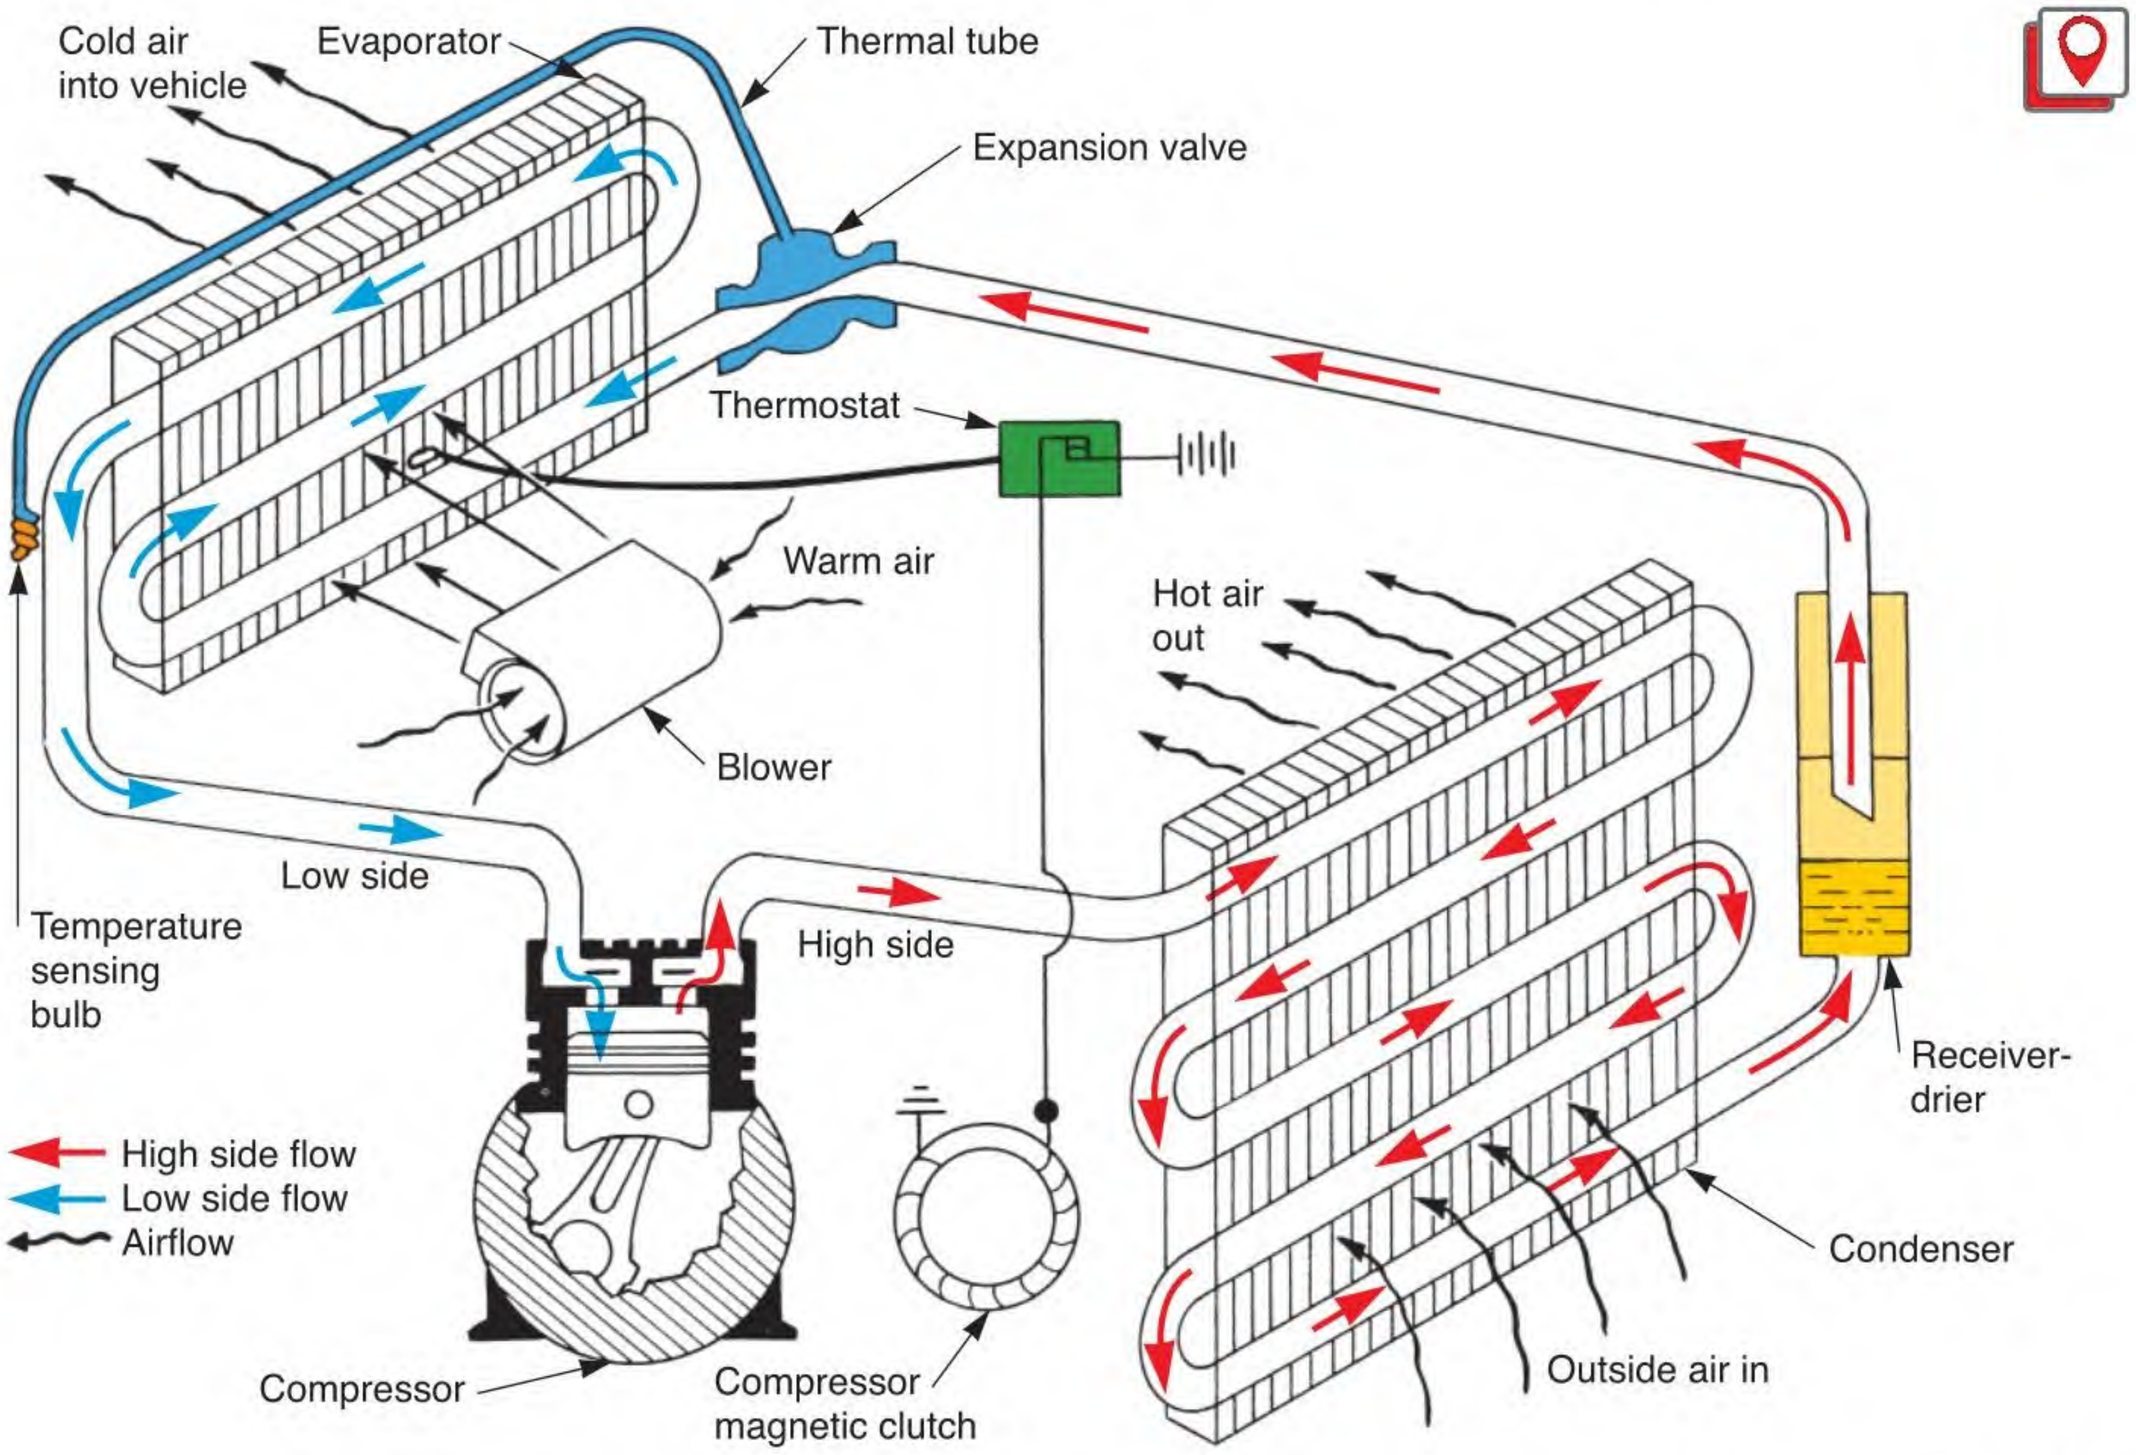
Goodheart-Willcox Publisher

Figure 83-5. Refrigerant can be used to cool object when it vaporizes. It releases gathered heat when it condenses.

Deere & Co.

Figure 83-6. Study this diagram showing the basic refrigeration cycle.

Basic Refrigeration Cycle



In the ***basic refrigeration cycle***, the refrigerant goes through four phases: compression, condensation, expansion, and vaporization. See **Figure 83-6**. When the refrigerant condenses, heat transfers out of it and into the surrounding air. Then, when the refrigerant evaporates, it absorbs heat to cool the air in the surrounding area.

Figure 83-7 illustrates the operation of a refrigeration system. The eight basic parts of a typical refrigeration system include:

- Refrigerant—Refrigerant is a substance, usually R-134a, that carries heat through the system to lower the air temperature in the vehicle.
- Compressor—The compressor is an engine-driven or electric pump that pressurizes refrigerant and forces it through the system.
- Condenser—The condenser causes refrigerant to change from a gaseous state to a liquid state, causing it to give off its stored heat.
- Flow-control device—A flow-control device, usually an expansion valve or tube, causes refrigerant pressure and temperature to drop, cooling the evaporator.
- Evaporator—An evaporator uses the cooling action of vaporizing refrigerant to cool the air inside the vehicle.
- Receiver-drier or accumulator—A receiver-drier or accumulator removes moisture from and stores refrigerant.
- Blower—The blower is a fan that forces air through the evaporator and into the passenger compartment.
- Thermostatic switch—Thermostatic switch shuts the compressor off when the evaporator temperature nears freezing.

Refrigerant circulates inside the system. The compressor pressurizes the refrigerant and forces it into the condenser, where it condenses into a liquid. Heat is transferred into the condenser and then into the outside air. Liquefied refrigerant then flows to a flow-control restriction (orifice tube or expansion valve). As it passes through the restriction, its pressure suddenly drops. This makes the refrigerant turn into a vapor as it enters the evaporator. The refrigerant absorbs heat from the evaporator, and the evaporator becomes very cold.

Copyright Goodheart-Willcox Co., Inc.

Deere & Co.

Figure 83-7. The fundamental parts and action of an automotive air conditioning system.

Since the blower forces air through the evaporator, cold air blows into the area to be cooled. The refrigerant vapor is then pulled back into the compressor for another cycle.

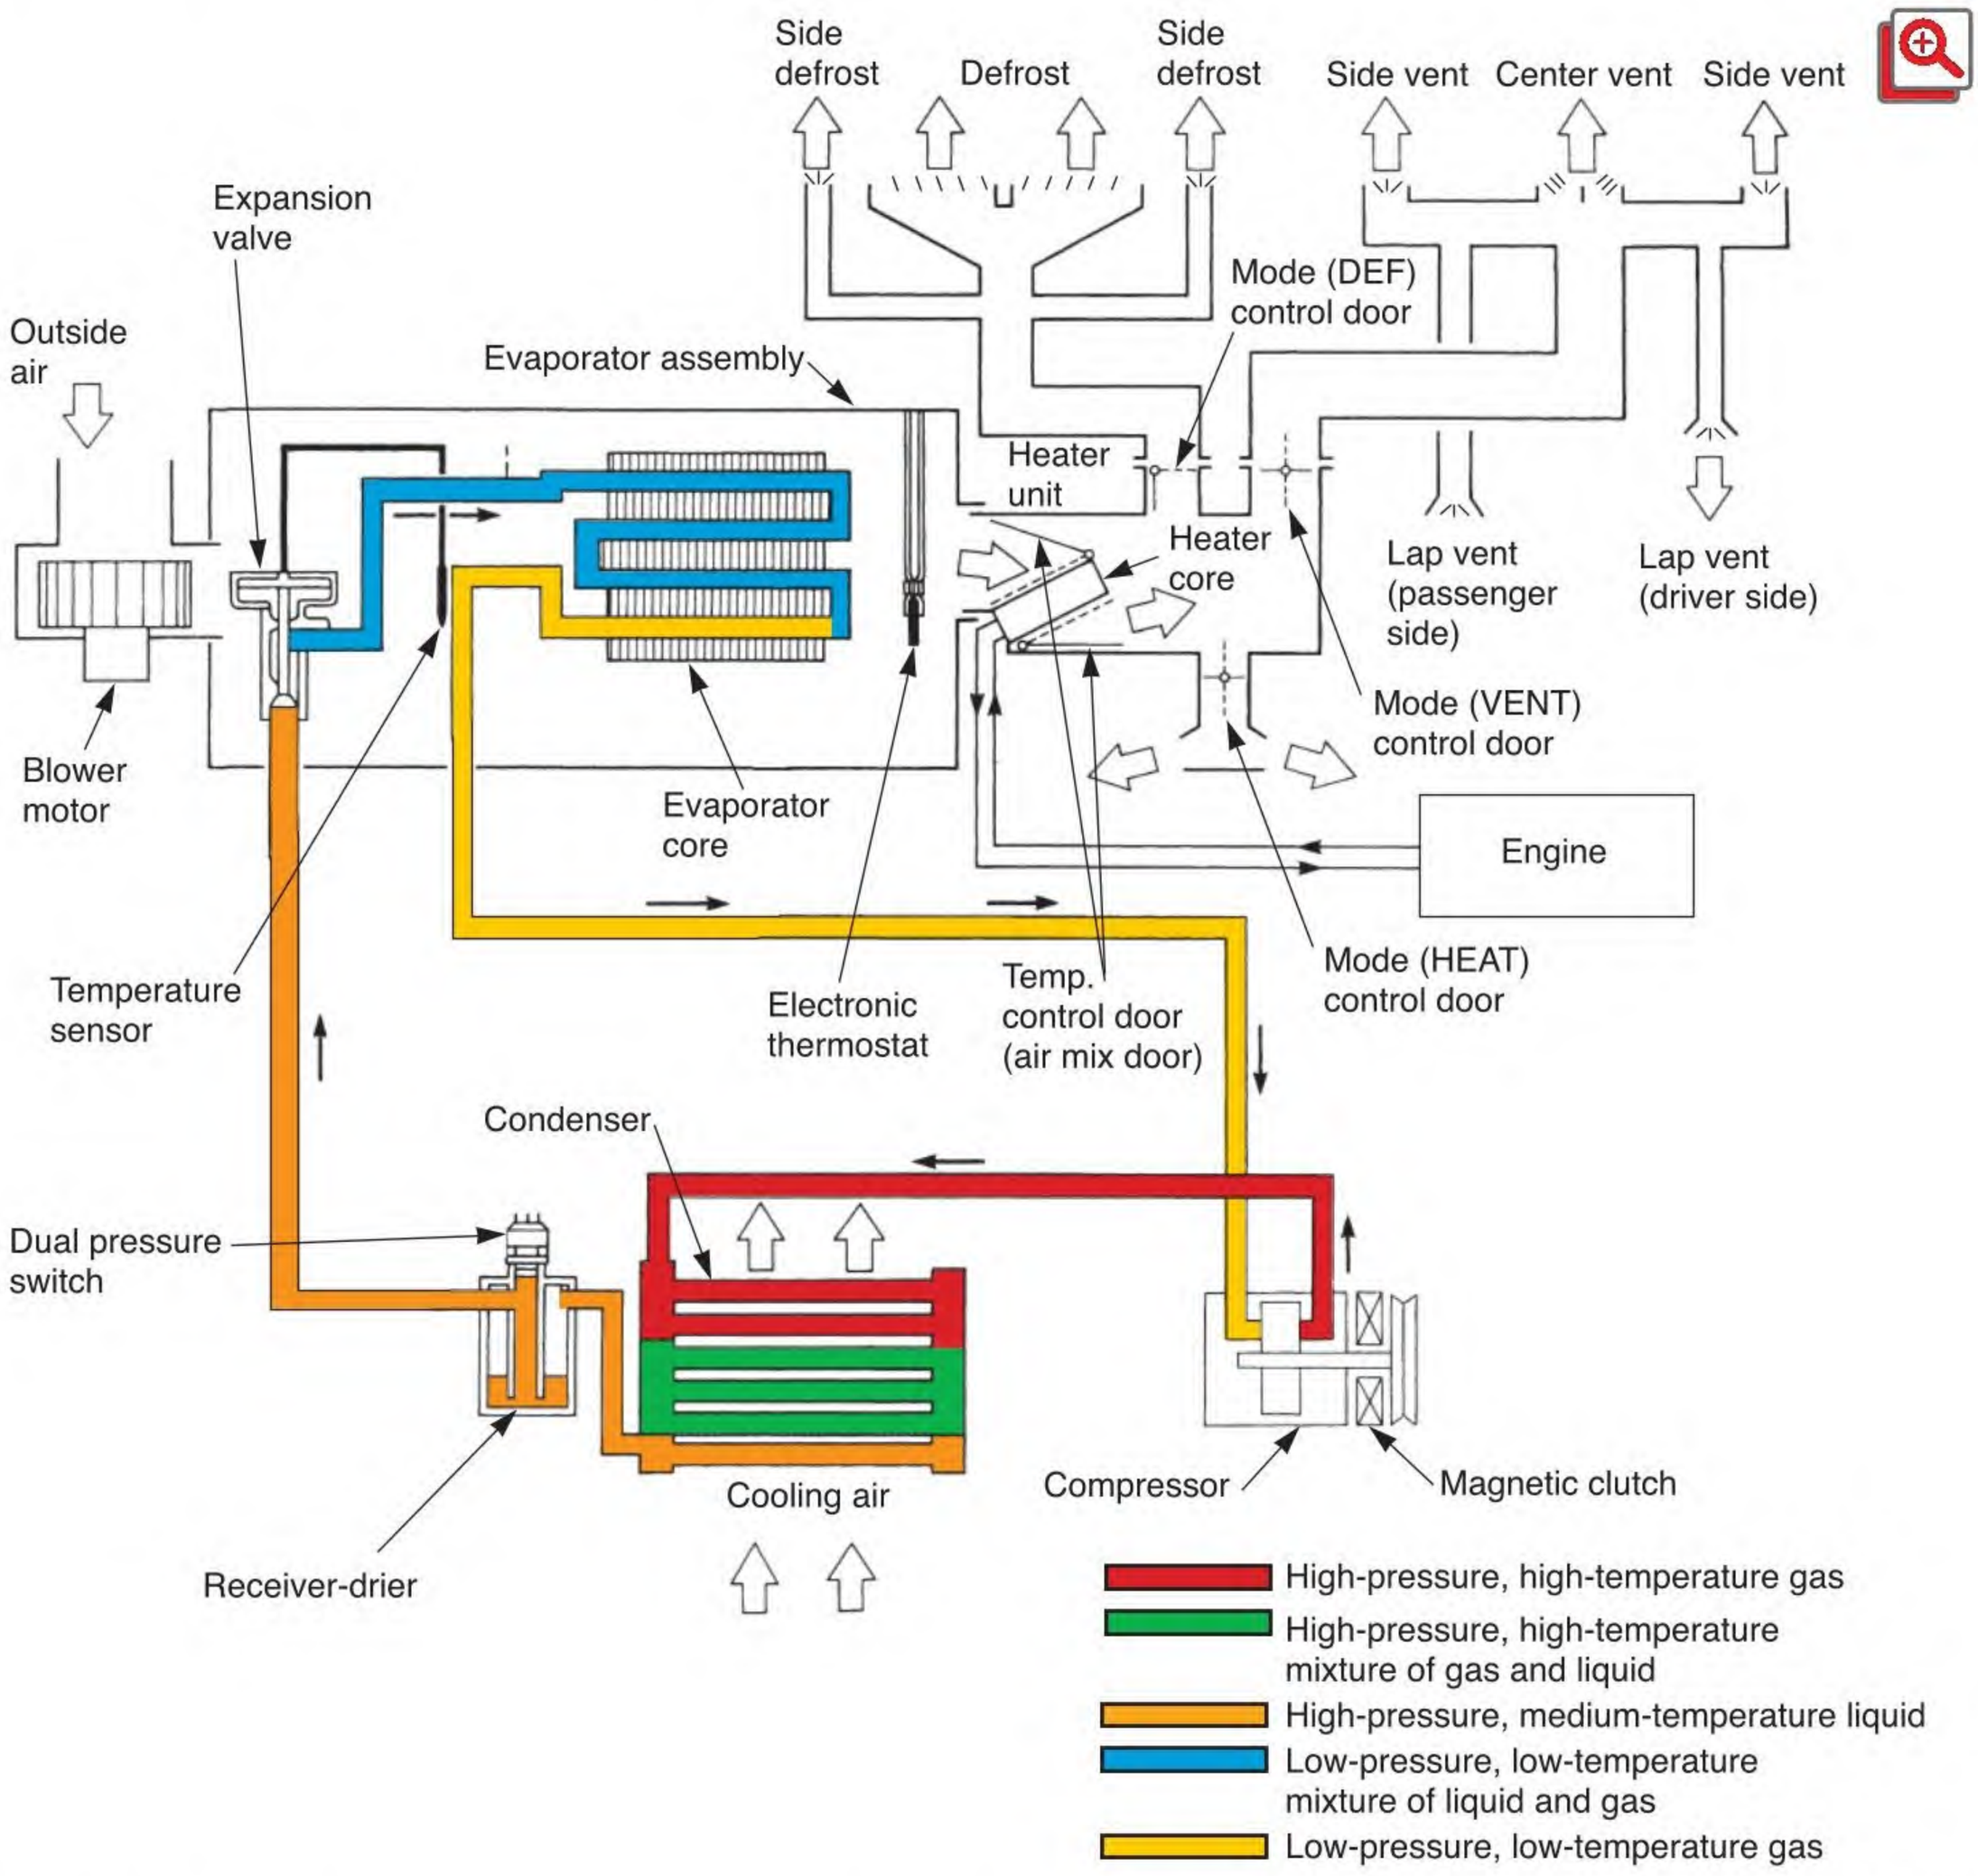
Automotive Air Conditioning System

An automotive air conditioning system (A/C system) performs four basic functions—it cools, dehumidifies (dries), cleans, and circulates the air in the vehicle. Additional components (valves, ducts, flaps, and switches) increase system efficiency and dependability, **Figure 83-8**.

High and Low Sides

There are two major divisions of an air conditioning system: the high side and the low side, **Figure 83-9**.

The ***high side***, or ***discharge side***, of an A/C system consists of the parts between the output of the compressor and the flow-control restriction. All the lines and other parts operating on high pressure are in the high side of the system.



The ***low side***, or ***suction side***, of an A/C system consists of the parts between the flow-control restriction and the inlet of the compressor. All these parts operate on low pressure.

Air Conditioning Compressor

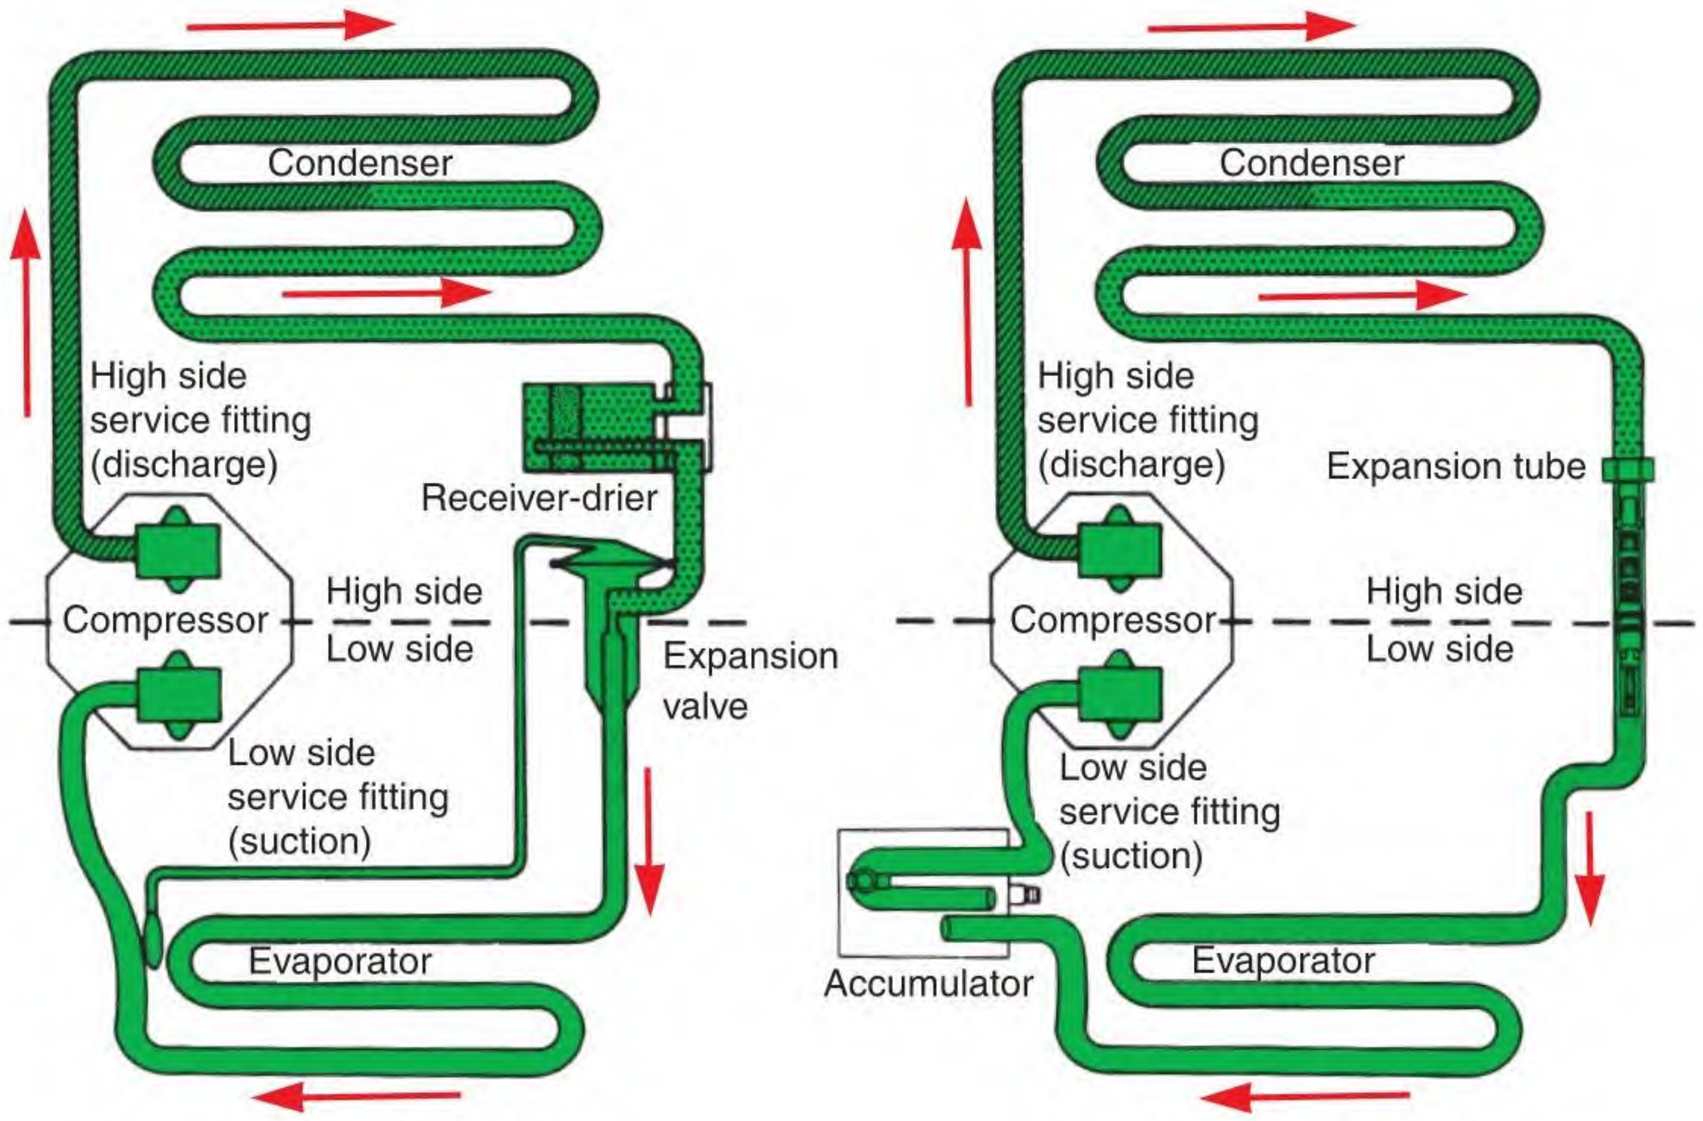
An ***air conditioning compressor*** is a refrigerant pump that is bolted to the front of the engine. It is normally driven by a V-belt or a ribbed-type belt from the engine crankshaft pulley, **Figure 83-10**. Although exact designs vary, an A/C compressor operates as shown in **Figure 83-11**.

In a piston-type compressor, a piston is forced to slide up and down in a cylinder. This produces an intake (suction) stroke when the piston moves down

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

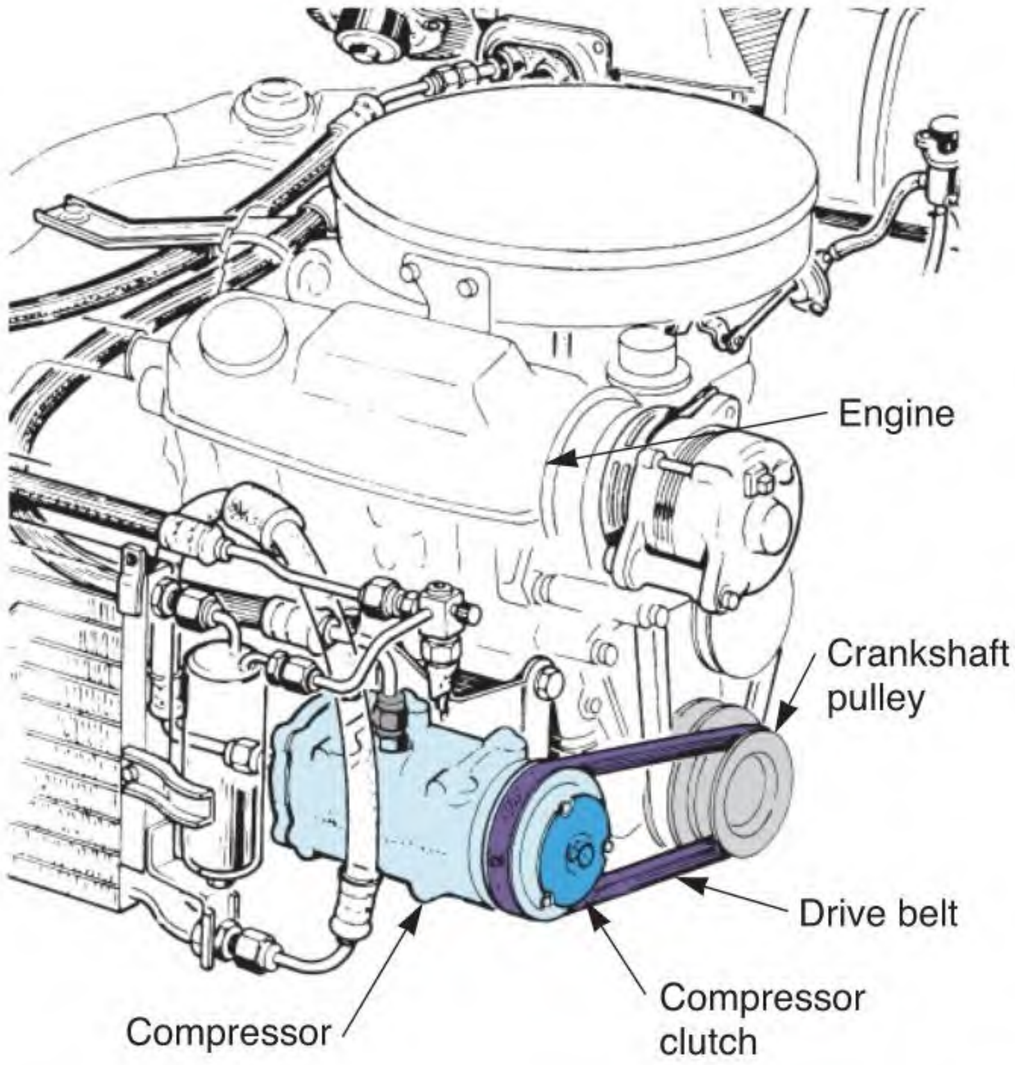
Figure 83-8. Trace the flow of refrigerant liquid and vapor through the system. Also study airflow through the vents.



and an output (pressure) stroke when the piston moves up.

A ***reed valve*** is simply a thin piece of metal that bends to open and close an opening. Reed valves are normally used as check valves to produce flow through the compressor and system, **Figure 83-12**.

A ***magnetic clutch*** is used to engage and disengage the air conditioning system compressor. A magnetic clutch typically consists of an electric coil, a pulley, and a front clutch plate. These parts bolt around or on the compressor shaft. See **Figure 83-13**.



When current is passed through the compressor coil, a strong magnetic field develops. The magnetic field pulls the front clutch plate into contact with the compressor pulley. This locks the clutch plate and pulley together. The compressor shaft then rotates to operate the internal parts of the compressor, **Figure 83-14**.

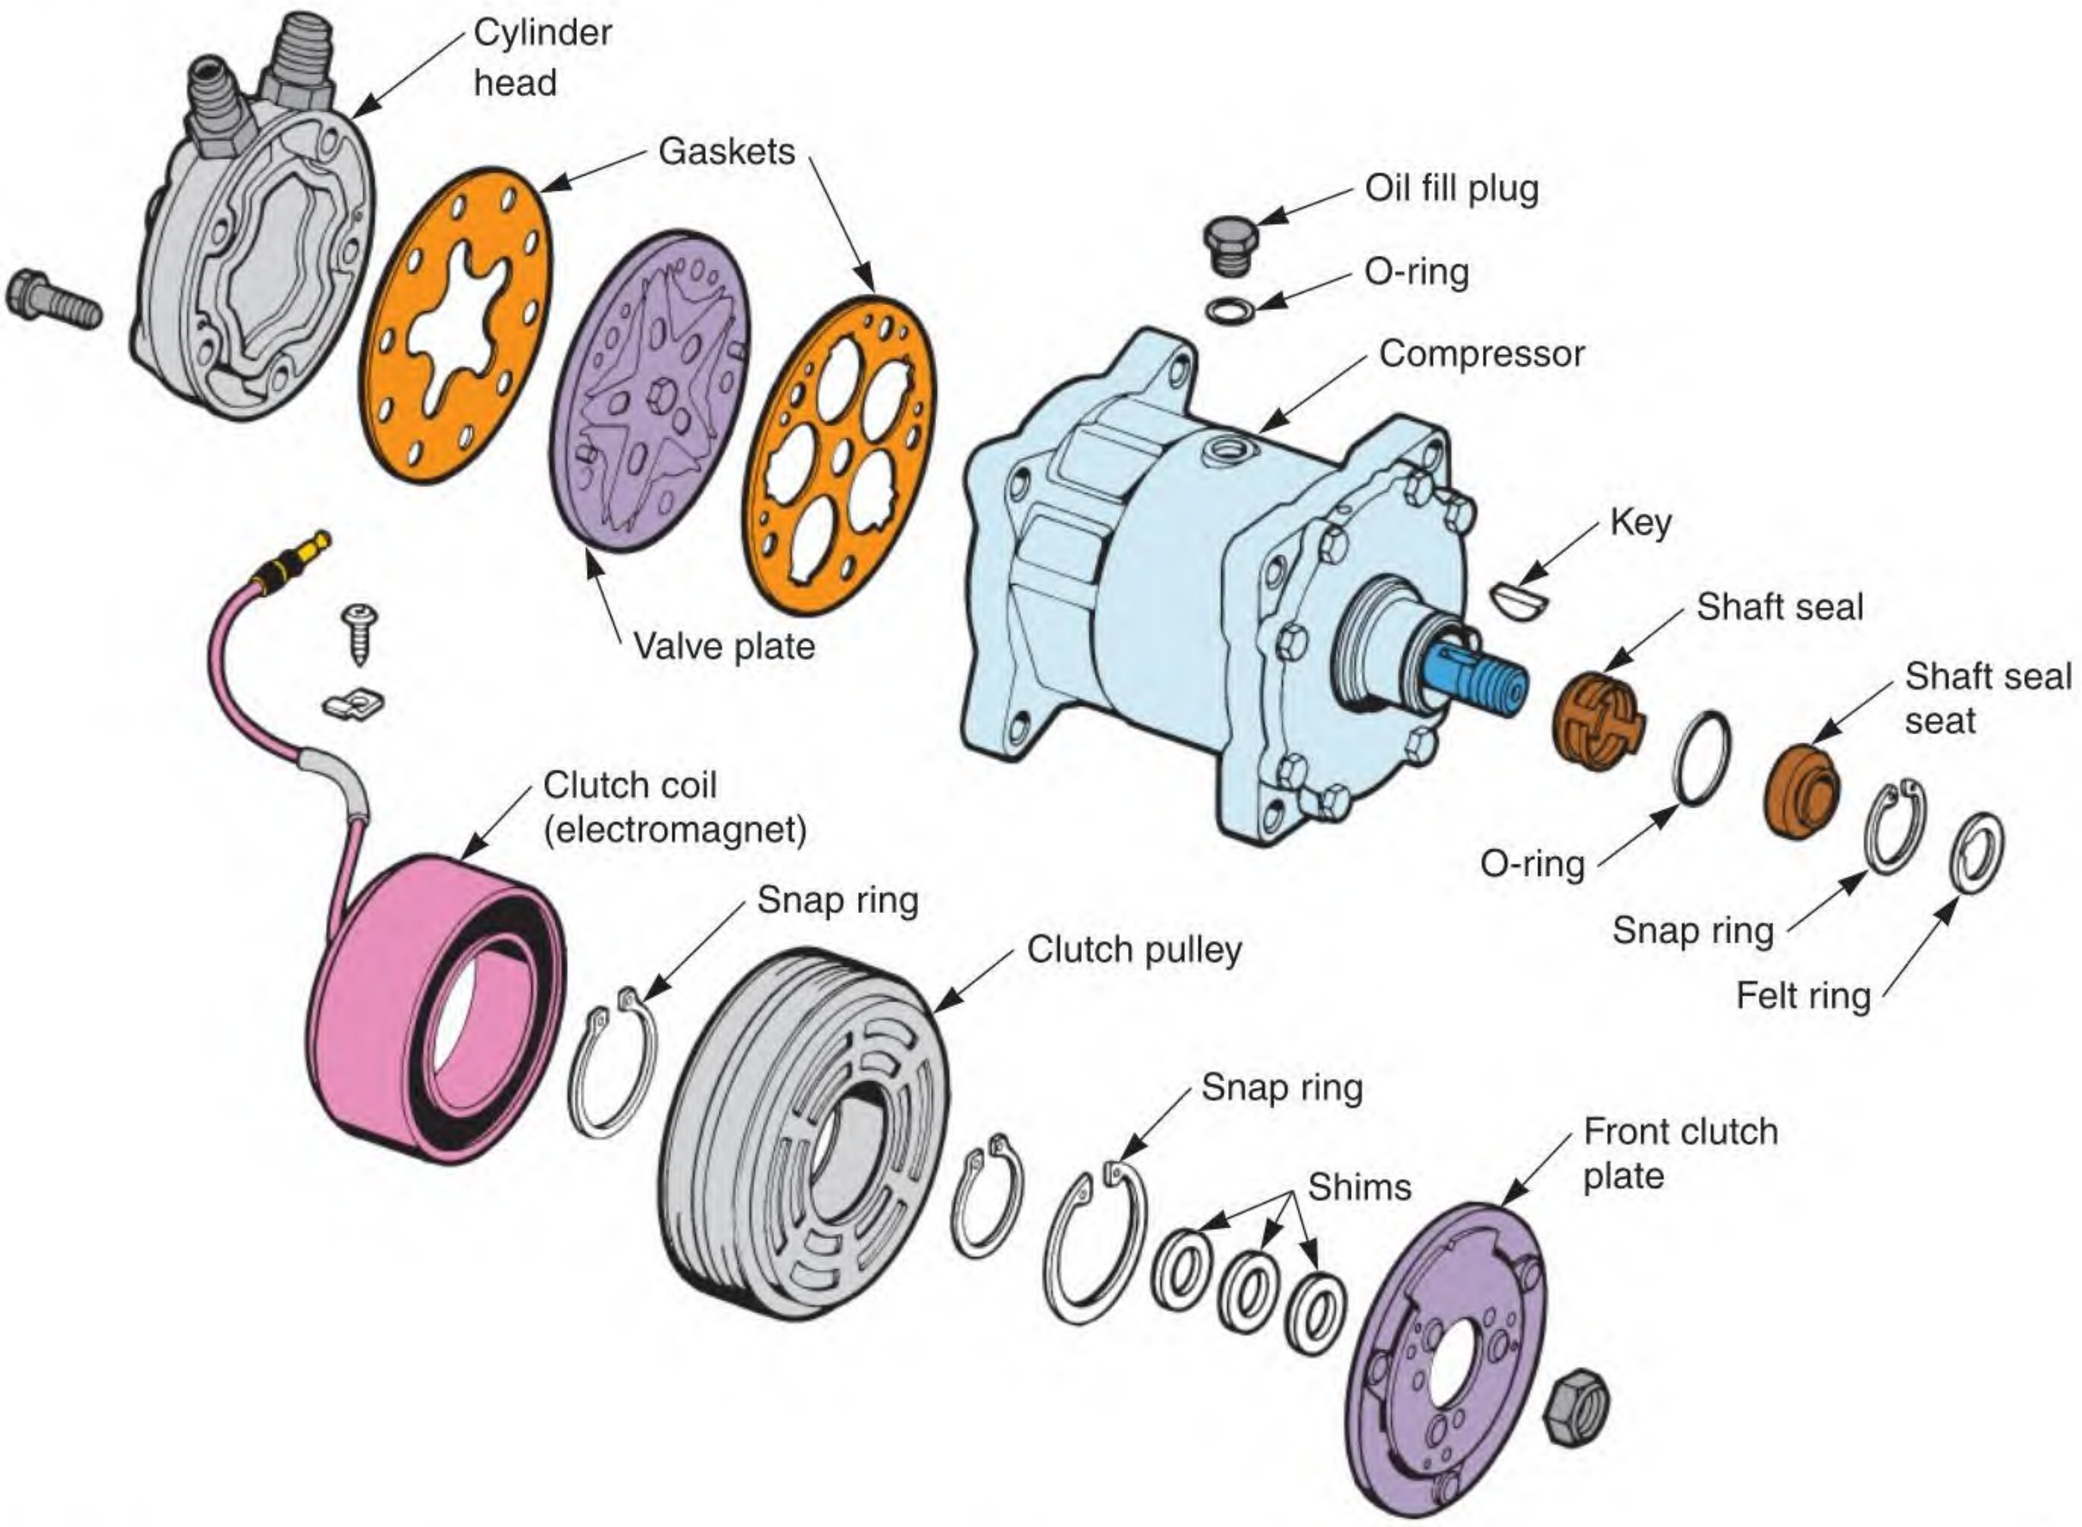
Figure 83-12. Compressor reed valves control flow in and out of the compressor. Note how they mount in the unit.

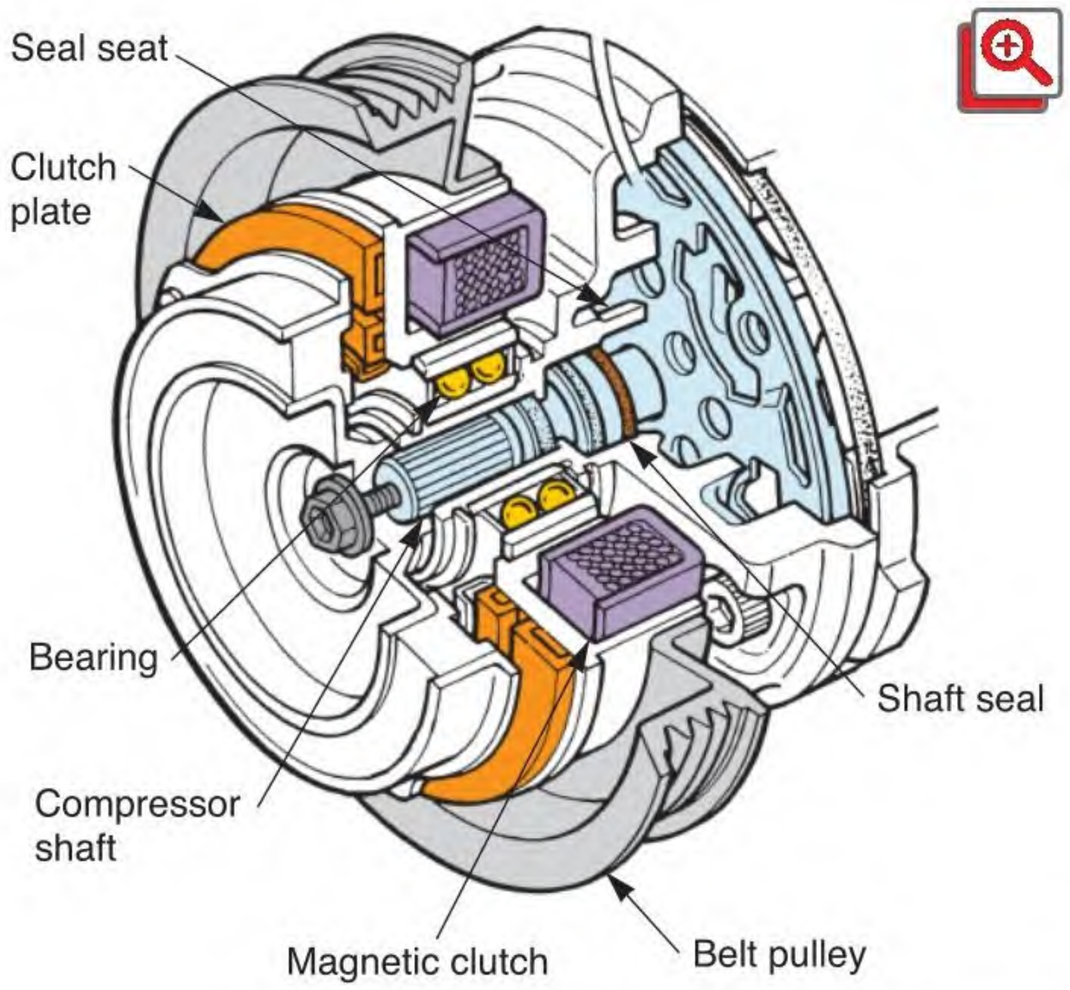


When current to the compressor coil is shut off, the clutch plate is released from the compressor pulley. This lets the pulley freewheel, so the compressor doesn't function.

Compressor Types

There are five types of automotive air conditioning compressors:

- Crank compressor (inline or V-type), **Figure 83-15**.
- Axial compressor, **Figure 83-16**.
- Radial compressor, **Figure 83-17**.
- Rotary vane compressor, **Figure 83-18**.
- Scroll compressor, **Figure 83-19**.



Compare the shape and construction of each type. Note that three of the five types use pistons, cylinders, and reed valves to produce system pressure. The main difference is the position of these parts.

Figure 83-15. A crank-type compressor is similar to a small gasoline engine. The crankshaft, connecting rods, and pistons make up the reciprocating assembly.

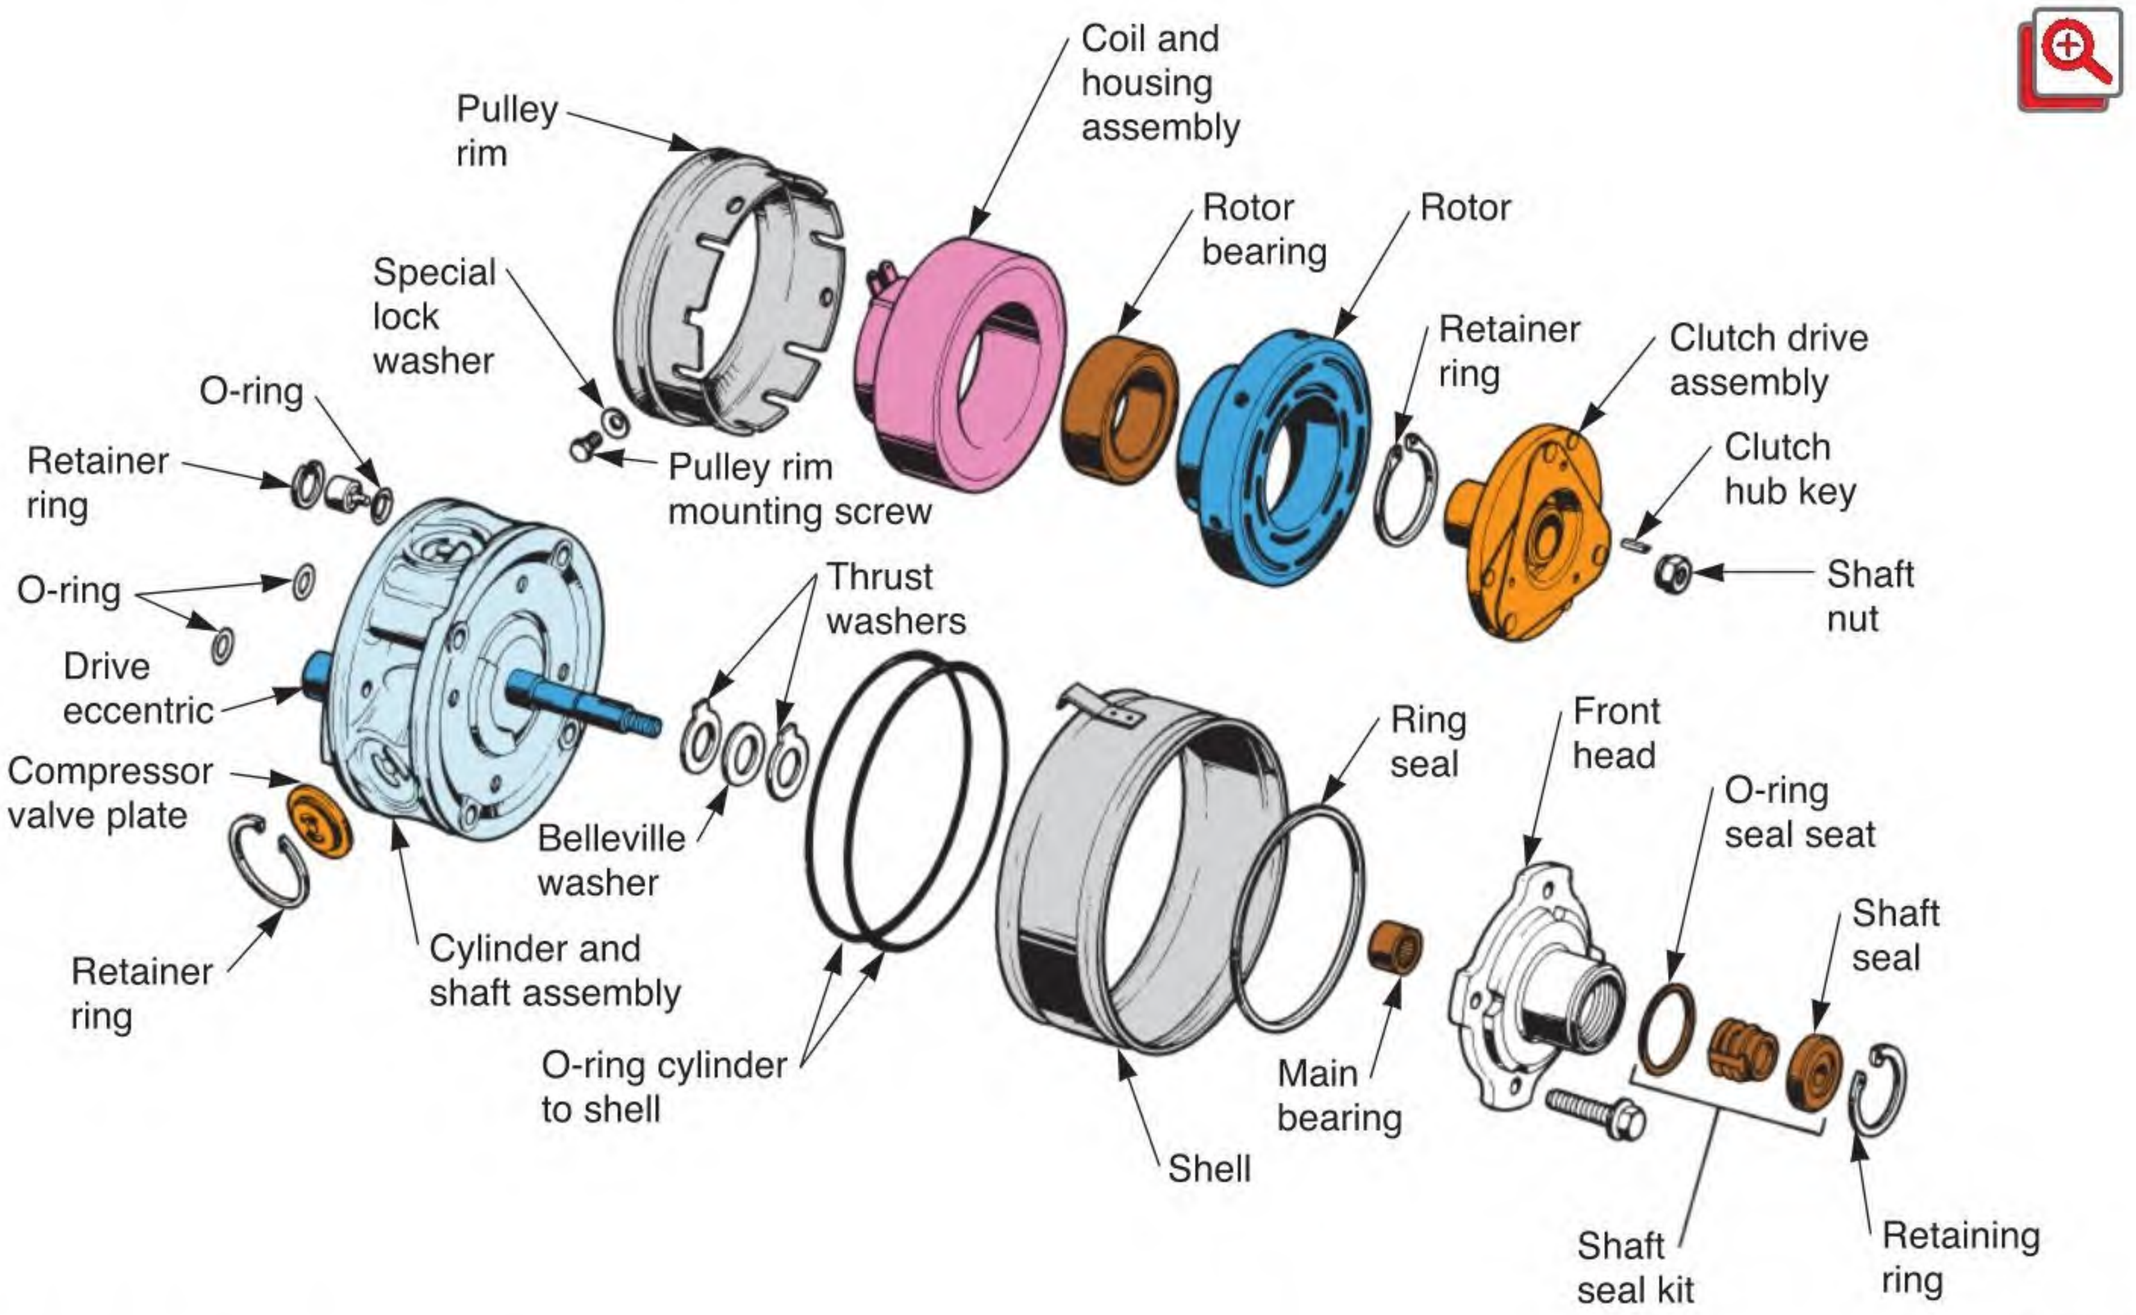
Mitchell Manuals

Figure 83-16. An axial compressor has pistons moving lengthwise in its body. The swash plate moves the pistons.

The crank compressor uses a *crankshaft* that is similar to the crankshaft used in an automotive engine. The axial compressor uses a *swash plate* to produce piston motion. A *shaft eccentric* (egg-shaped component) causes piston movement in a radial compressor.

Vanes (blades), similar to those found in oil or power steering pumps, pressurize the refrigerant in a rotary vane compressor. A scroll compressor uses two scrolls—one movable and one stationary—to pressurize the refrigerant.

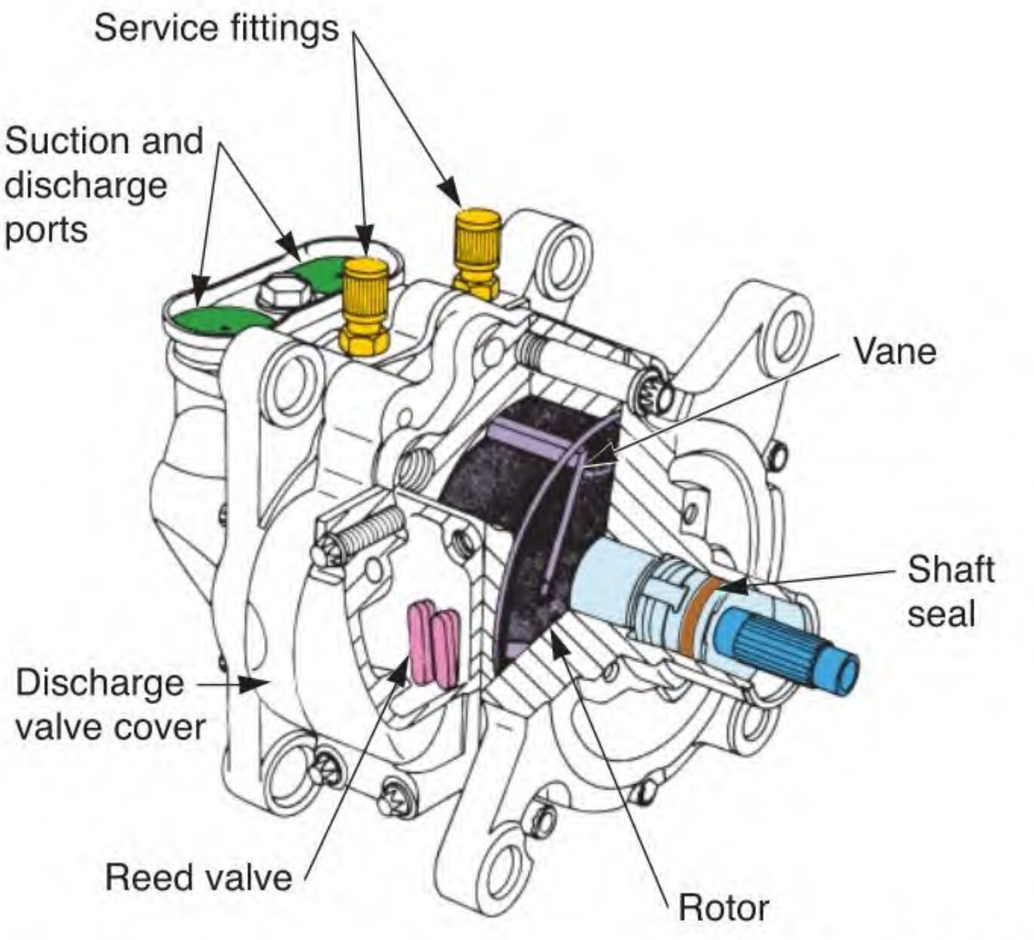
Refrigerant Oil



Refrigerant oil is high-viscosity, highly refined (pure) oil used to lubricate the parts of the air conditioning system, especially the compressor. Because the refrigerant oil and the refrigerant mix, oil droplets are carried throughout the system. The refrigerant oil also splashes around inside the compressor to reduce friction and wear.

Refrigerant Hoses

Refrigerant hoses carry refrigerant to each air conditioning system component and back to the compressor. These special high-pressure hoses are designed to withstand compressor pressures as high as 250 psi (1725 kPa). See **Figure 83-20**.



Special fittings are used on the ends of refrigerant hoses. O-ring seals, hose clamps, or flared tube ends are used on the fittings to prevent leakage. Look at **Figure 83-21**.

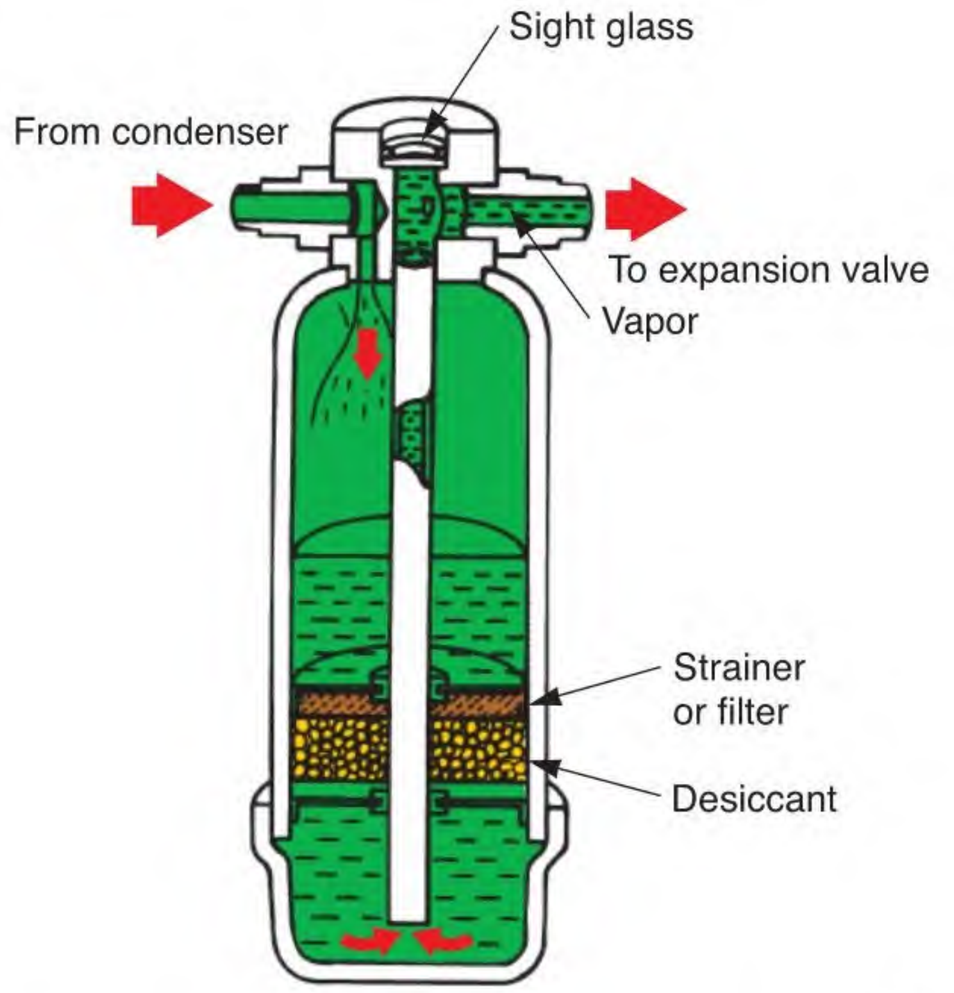
Figure 83-21. Note the common types of fittings found in automotive air conditioning systems.

Air Conditioning Condenser

An ***air conditioning condenser*** is a radiator-like device that transfers heat from the refrigerant to the outside air. It normally bolts in front of the cooling system radiator, as shown in **Figure 83-20**.

The condenser is simply a long metal tube wound back and forth between hundreds of metal fins. The fins increase the condenser's surface area, improving heat transfer.



Receiver-Drier

A ***receiver-drier*** removes moisture from the system and stores extra refrigerant. It is normally located in the high side of the system. A cutaway view of a typical receiver-drier is shown in **Figure 83-22**. Note that the unit contains a *desiccant* (drying agent), which removes water from the refrigerant.

A ***sight glass*** may be located in the top of the receiver-drier to show the amount of refrigerant in the system. If the system is low on refrigerant, bubbles will show up in the sight glass. The sight glass can also be located in one of the refrigerant lines.

Accumulator

An ***accumulator*** performs the same function as a receiver-drier: it stores and dries the refrigerant.

Nissan

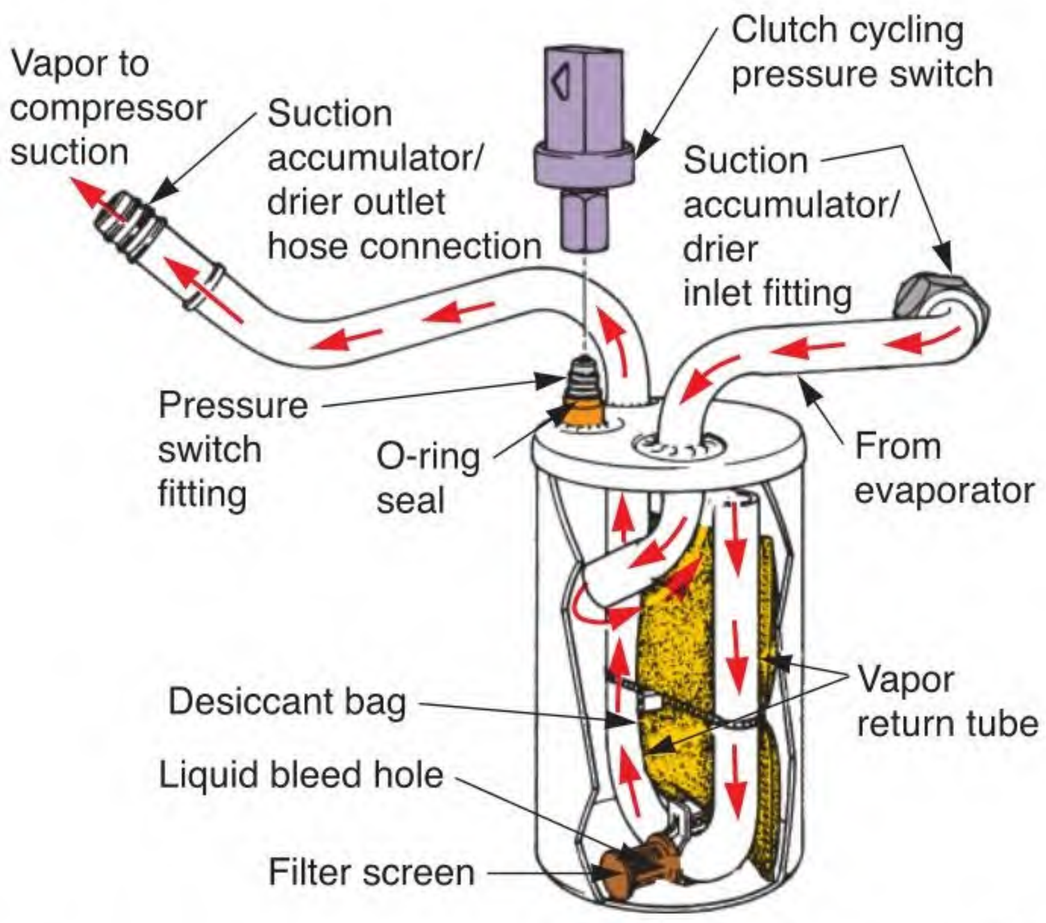
Figure 83-22. The receiver-drier, or dehydrator, removes moisture from the air conditioning system.

Copyright Goodheart-Willcox Co., Inc.

However, it is normally on the system's low side (at the evaporator outlet). Look at **Figure 83-23**.

The accumulator keeps liquid refrigerant from entering the compressor. The compressor can be damaged by liquid refrigerant because liquids do *not* compress. The construction of receiver-driers and accumulators varies.

Muffler



A ***muffler*** is a hollow container that quiets the pumping sounds produced by the compressor. It is usually a metal can formed into the high-pressure, or compressor discharge, refrigerant line.

Evaporator

The ***evaporator***, like the condenser, is a refrigerant coil mounted in cooling fins. The evaporator is usually mounted on the right side of the vehicle. It fits inside the blower housing, either on the outside or inside of the firewall.

Air Conditioning System Controls

All A/C systems use a compressor, a condenser, an evaporator, a drier, and/or an accumulator. However, many different devices are used to control the operation of the compressor and to meter the flow of refrigerant.

Ford

Figure 83-23. An accumulator serves as a reservoir and a moisture trap. Note how the clutch cycling switch mounts on the accumulator.

For example, the two most common types of air conditioning systems are:

- Expansion tube A/C system (cycling clutch system).
- Thermostatic expansion valve A/C system.

Over the years, other systems have been used. However, these two represent the most typical and easiest to understand A/C systems found on today's vehicles.

Expansion Tube A/C System

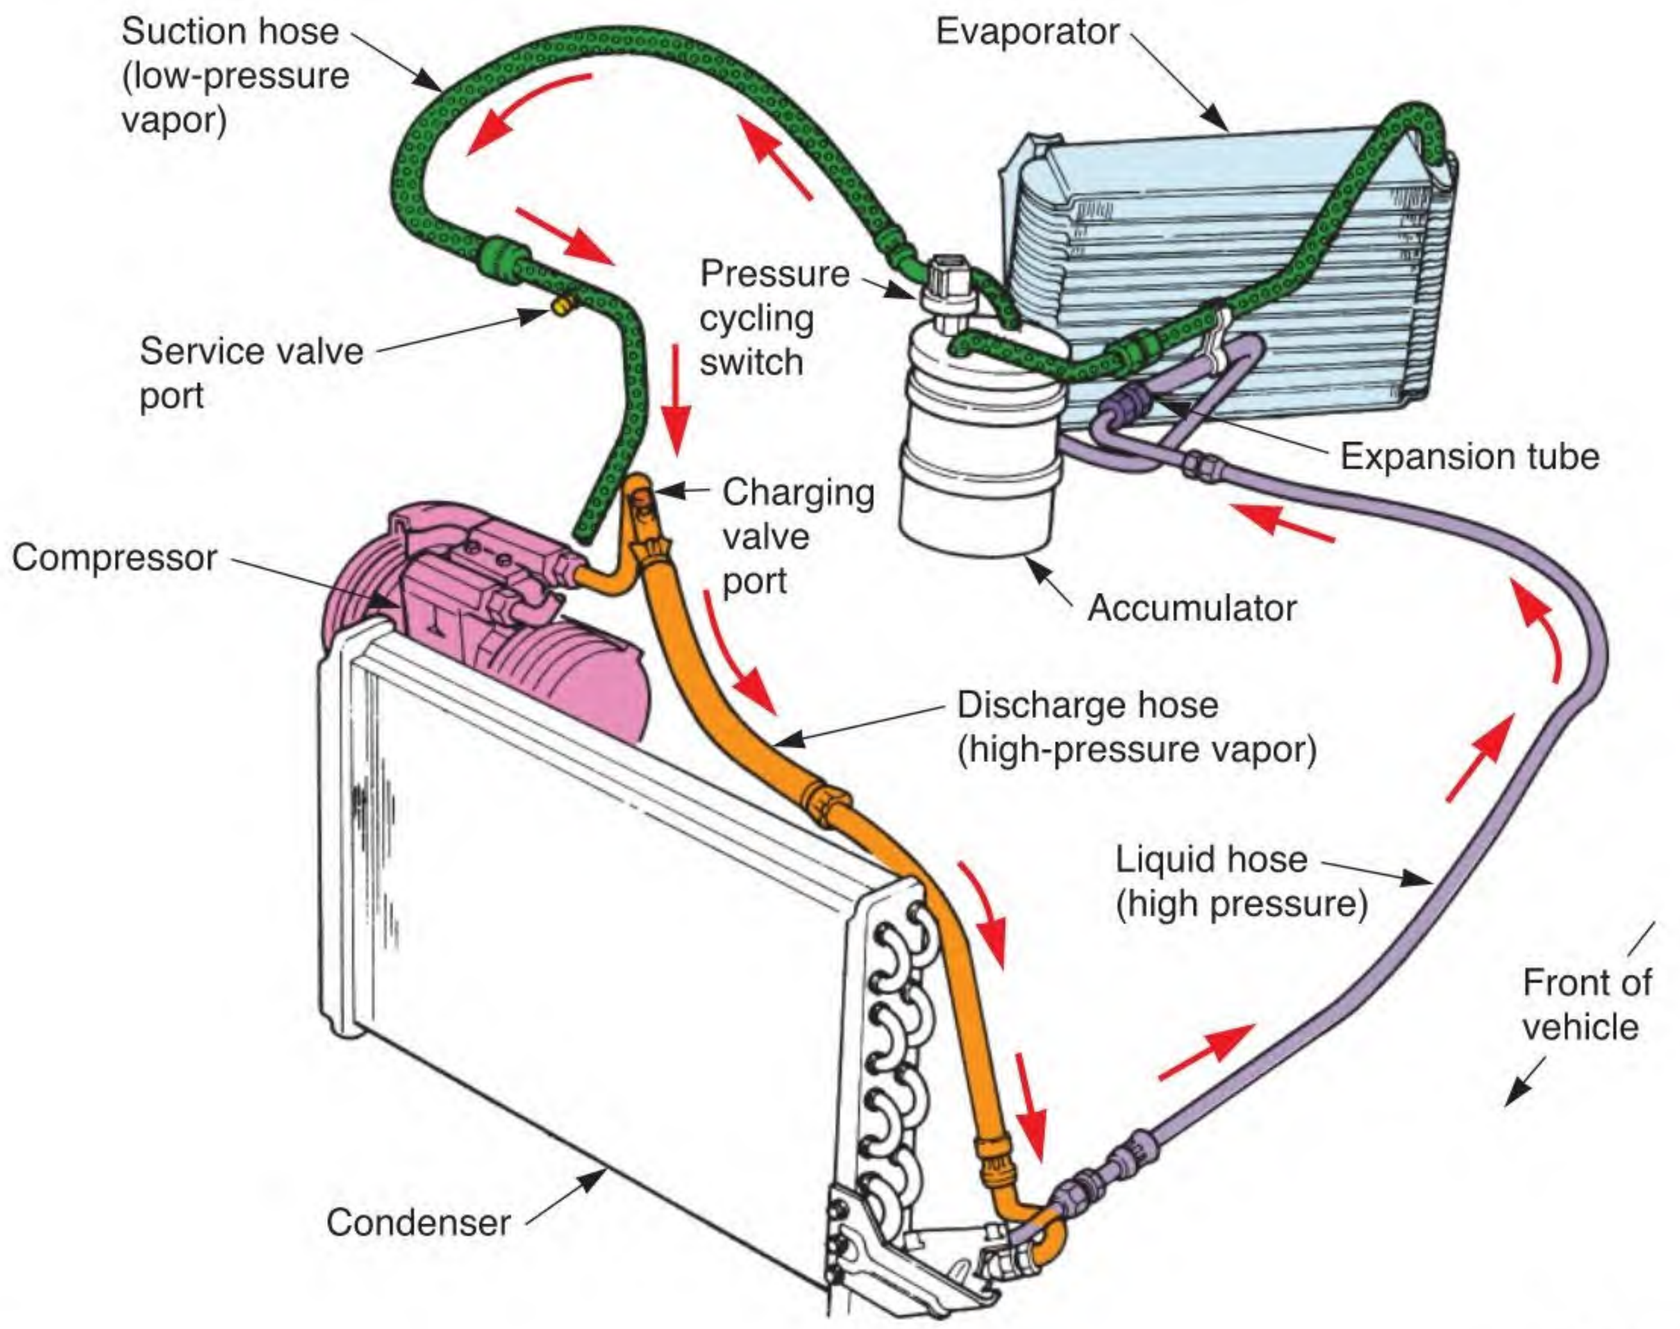
An ***expansion tube A/C system***, or ***cycling clutch system***, controls refrigerant flow and evaporator temperature by cycling the compressor on and off. This system is one of the simplest. Look at **Figure 83-24**.

The ***expansion tube*** (also called ***orifice tube***) has a fixed opening that meters the refrigerant flowing into the evaporator. The expansion tube usually fits near or in the evaporator inlet. It is usually a straight tube made of plastic or sintered metal, **Figure 83-25**.

Cycling Switches

Two types of ***compressor cycling switches*** can be used in an expansion tube A/C system: thermostatic cycling switches and pressure cycling switches.

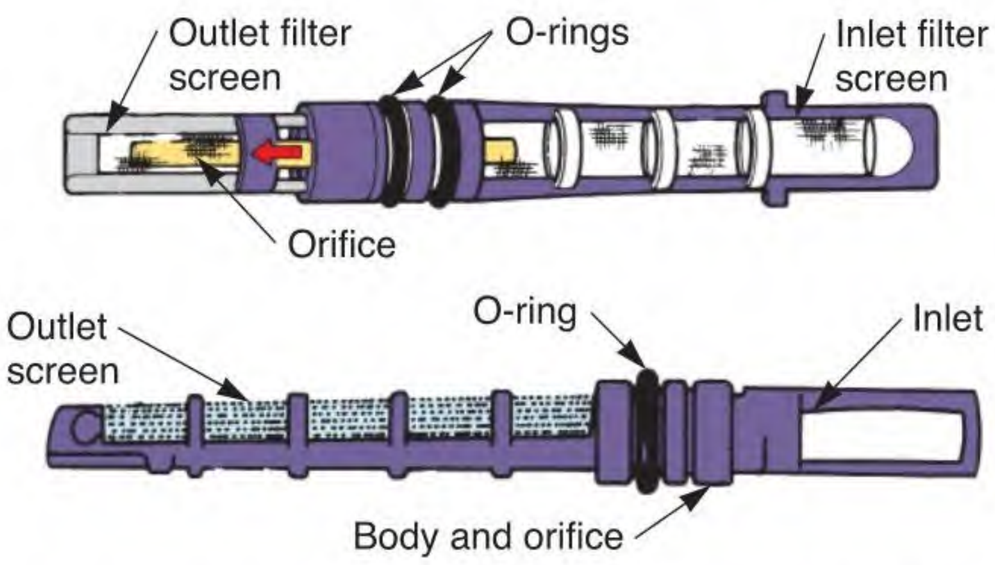
A ***thermostatic cycling switch*** turns the compressor on and off to maintain the correct evaporator temperature (approximately 32°F or 0°C).



When the evaporator is warm, the switch is closed and current flows to the compressor clutch coil. This causes the compressor to function, cooling the evaporator. Then, when the evaporator becomes cold enough (near freezing point), the cycling switch opens the circuit to the compressor clutch. This allows the evaporator temperature to increase as needed.

Since evaporator pressure determines evaporator temperature, a ***pressure cycling switch*** can be used in place of or in conjunction with a thermostatic switch to maintain the correct evaporator temperature. Note the location of the pressure cycling switch in **Figure 83-24**.

Expansion Valve A/C System



An ***expansion valve*** is a temperature-sensitive valve that controls refrigerant flow and the evaporator temperature. See **Figure 83-26**. Basically, an expansion

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

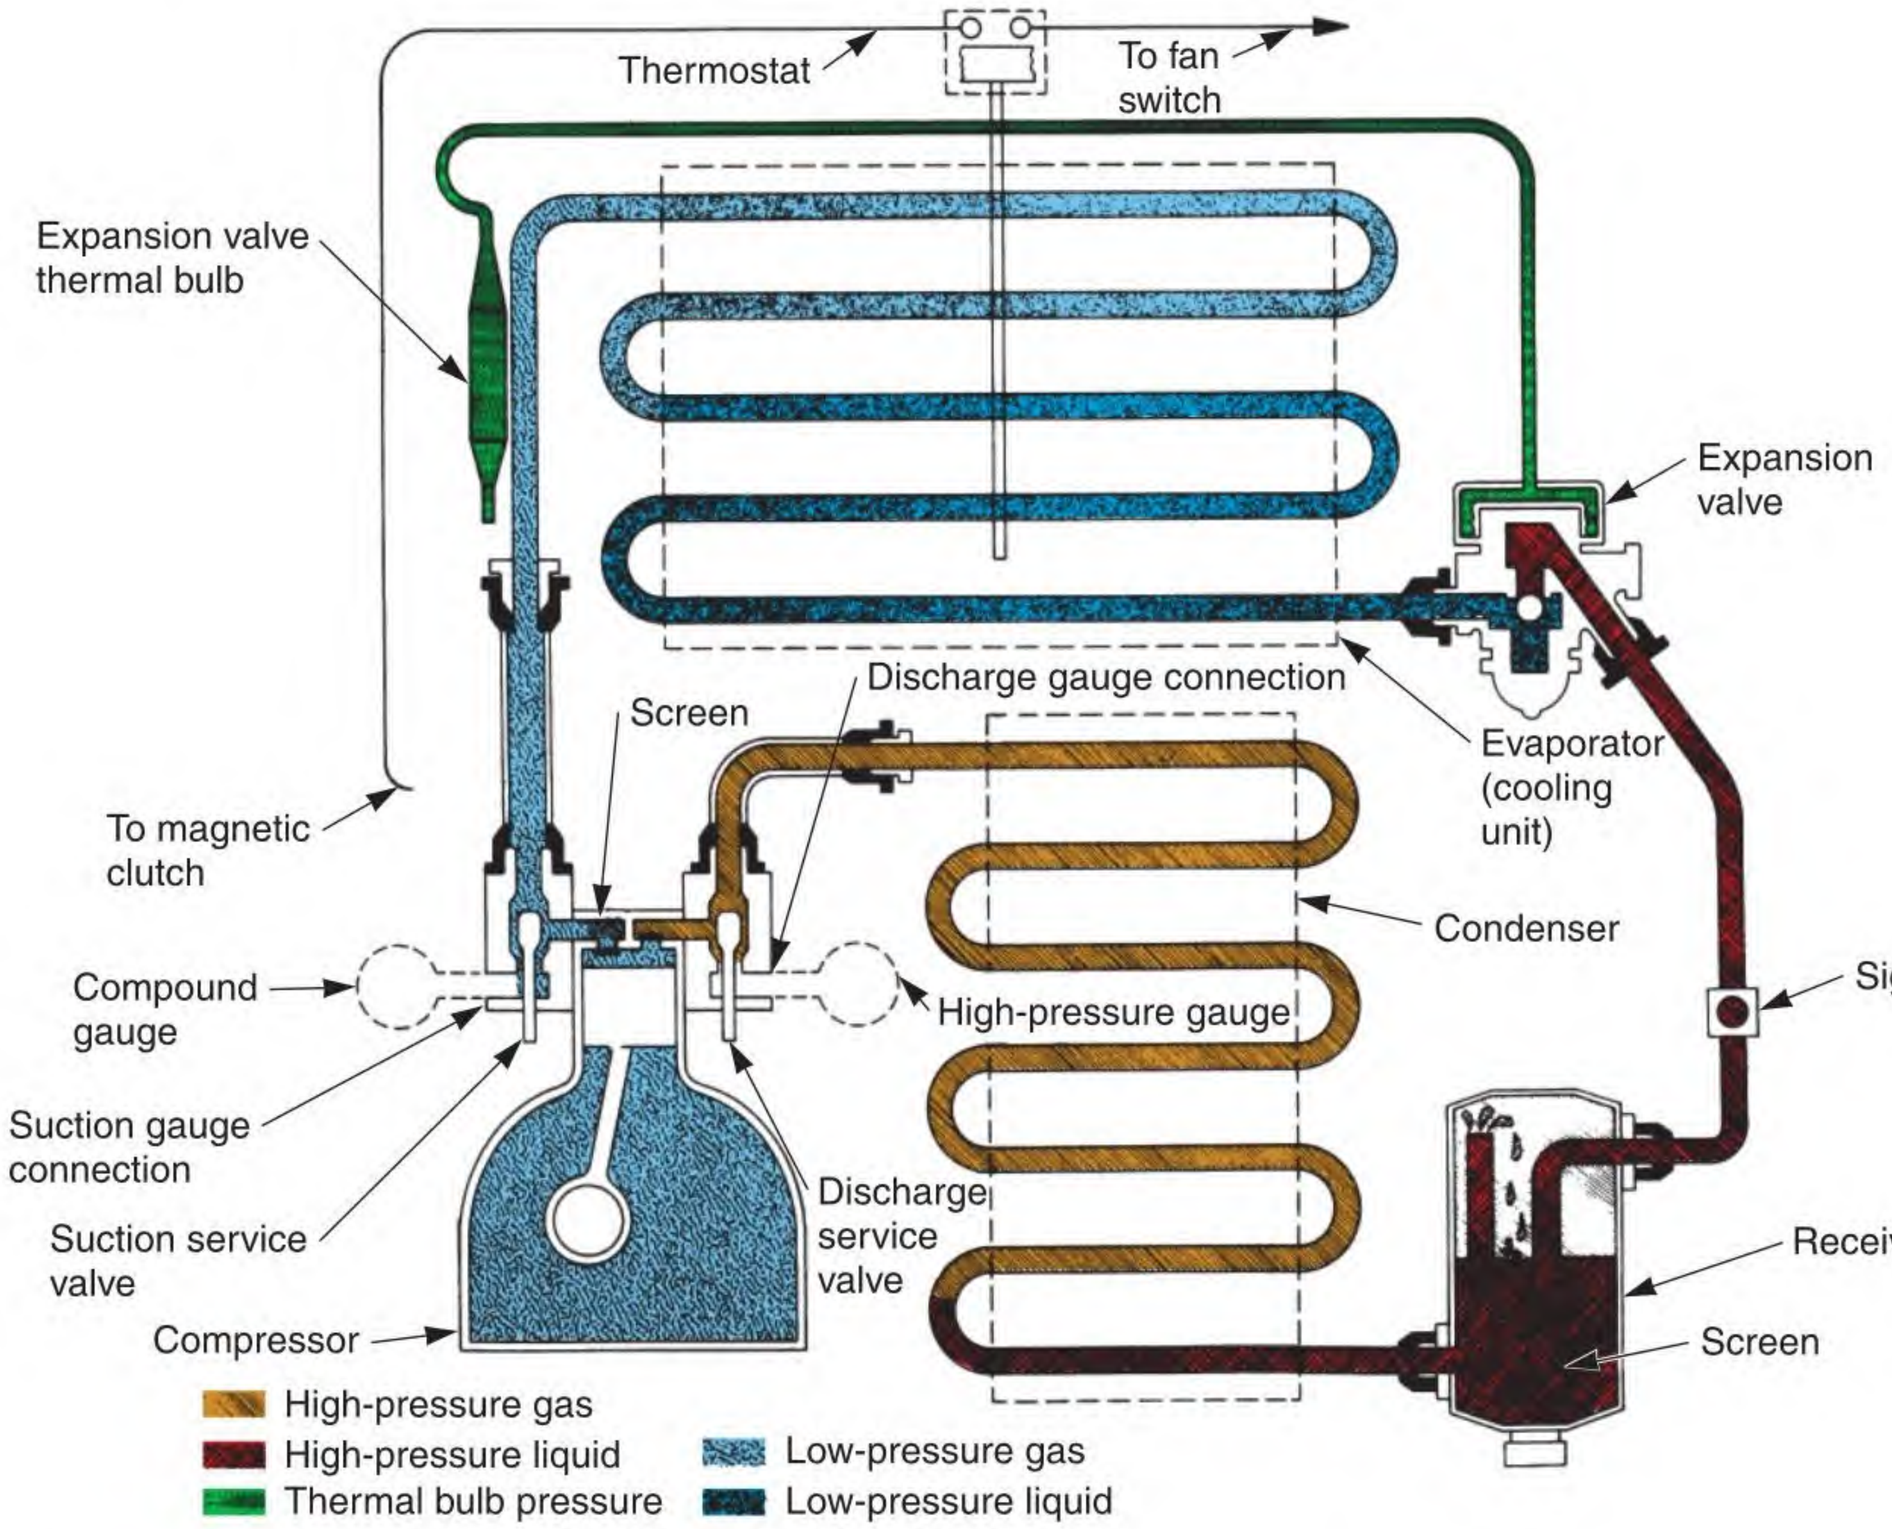
Figure 83-24. The expansion tube system turns the compressor on and off to control amount of refrigerant flowing through the evaporator. This provides a simple method of maintaining temperature.

Mitchell Manuals

Figure 83-25. The expansion tube has a metering orifice that allows a specific amount of refrigerant to enter the evaporator.

valve consists of a thermostatic bulb and tube, a diaphragm, actuating pins, a valve and seat, a metering orifice, and a spring. The compressor is not cycled on and off to control evaporator temperature—it runs all the time. So, the expansion valve can open and close to meter the right amount of refrigerant into the evaporator.

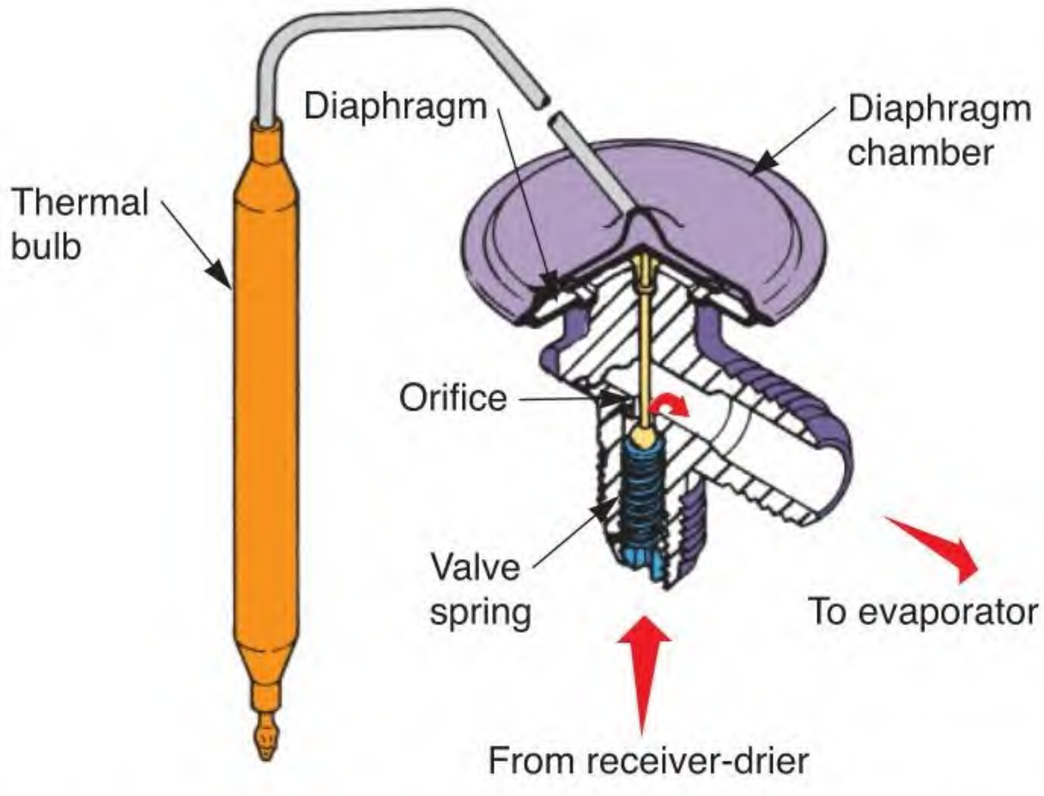
When the temperature of the evaporator and bulb is too warm, expansion in the thermostatic bulb places pressure on the diaphragm. This flexes the diaphragm, pushing the expansion valve open. More refrigerant then flows into the evaporator to provide more cooling. When the system becomes too cold, bulb pressure drops. When bulb pressure drops, the spring in the expansion valve closes the metering orifice to reduce refrigerant flow and cooling action, **Figure 83-27**.



Other A/C System Controls

Aside from the thermostatic cycling switch, the pressure cycling switch, and the expansion valve, other controls are needed to increase system efficiency and provide additional protection.

An ***ambient temperature switch*** can be used to keep the compressor from operating when the outside (ambient) air temperatures are very cold. This helps prevent seal, gasket, and reed valve damage.



A ***low-pressure cutout switch*** shuts off the compressor when system pressure drops below a certain point to prevent compressor damage. Low

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 83-26. This A/C system uses a thermostatic expansion valve. A thermal bulb senses evaporator outlet temperature and can open or close the expansion valve to maintain temperature.

Nissan

Figure 83-27. The expansion valve opens and closes with temperature changes to regulate the amount of refrigerant entering the evaporator.

system pressure can result from a refrigerant leak. The low-pressure cutout switch interrupts the circuit to the compressor clutch. If the compressor continues operating without refrigerant circulation, it could overheat and lock up.

A ***high-pressure cutout switch*** opens the compressor coil circuit when discharge pressure is too high. The switch opens when pressure reaches approximately 375 psi (2584 kPa). The high-pressure cutout switch is normally located in the service fitting of the discharge muffler. Like the low-pressure cutout switch, it prevents compressor damage from abnormal operating conditions.

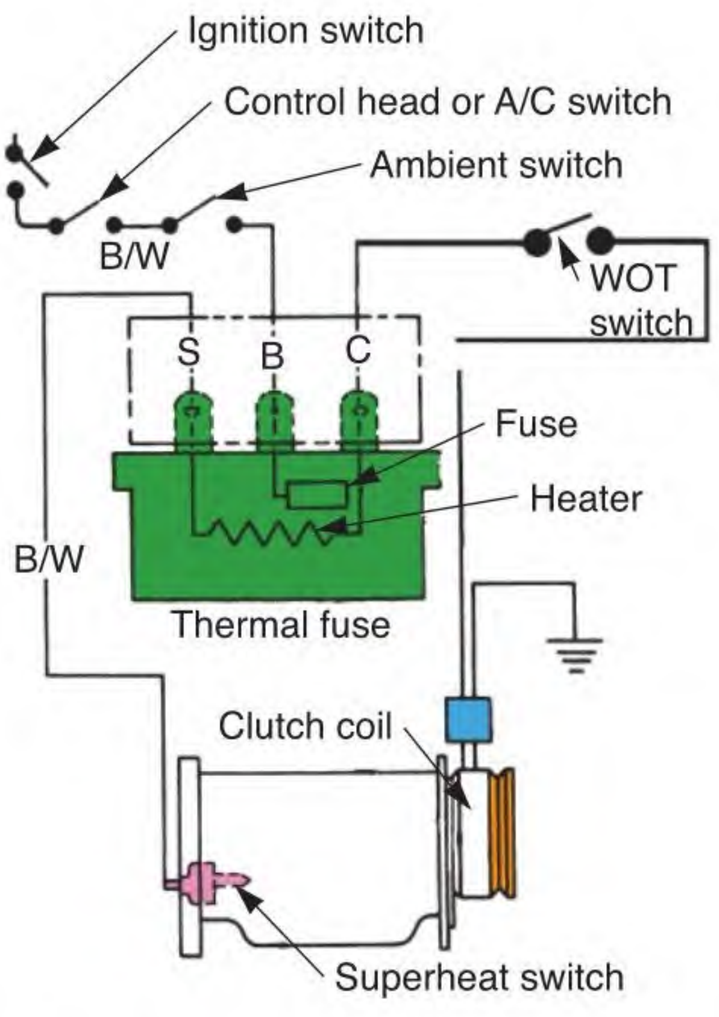
A ***thermal limiter*** and a ***superheat switch*** can prevent compressor damage when the refrigerant level or the oil level is too low. The superheat switch senses low system pressure and high compressor temperature, and sends current to the thermal

Copyright Goodheart-Willcox Co., Inc.

limiter. Current flow melts a fusible link in the thermal limiter and stops current to the compressor clutch. **Figure 83-28** shows these protection devices.

A ***pressure relief valve*** bleeds off excess pressure to prevent compressor damage. It is a pop-off (spring-loaded) valve located on the receiver-drier, compressor, or other component in the high side of the system.

The ***wide open throttle (WOT) switch*** shuts off the compressor during rapid acceleration to save power. This switch is used on cars with small gasoline or diesel engines. It is normally located on the accelerator linkage, carburetor, or throttle body, **Figure 83-28**.



The ***A/C switch*** is the driver-operated switch in the car's dash that feeds current to the compressor clutch and other electric components. The A/C switch provides a manual means of controlling system operation.

Service Valves

Service valves are basically provided to allow refrigerant installation and removal, as well as pressure gauge tests of the A/C system.

The ***discharge service valve*** is located at the output from the compressor, in the system high side.

The ***suction service valve*** is located at the inlet to the compressor, in the system low side.

AC-Delco

Figure 83-28. Study how switches are wired in an A/C system circuit.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

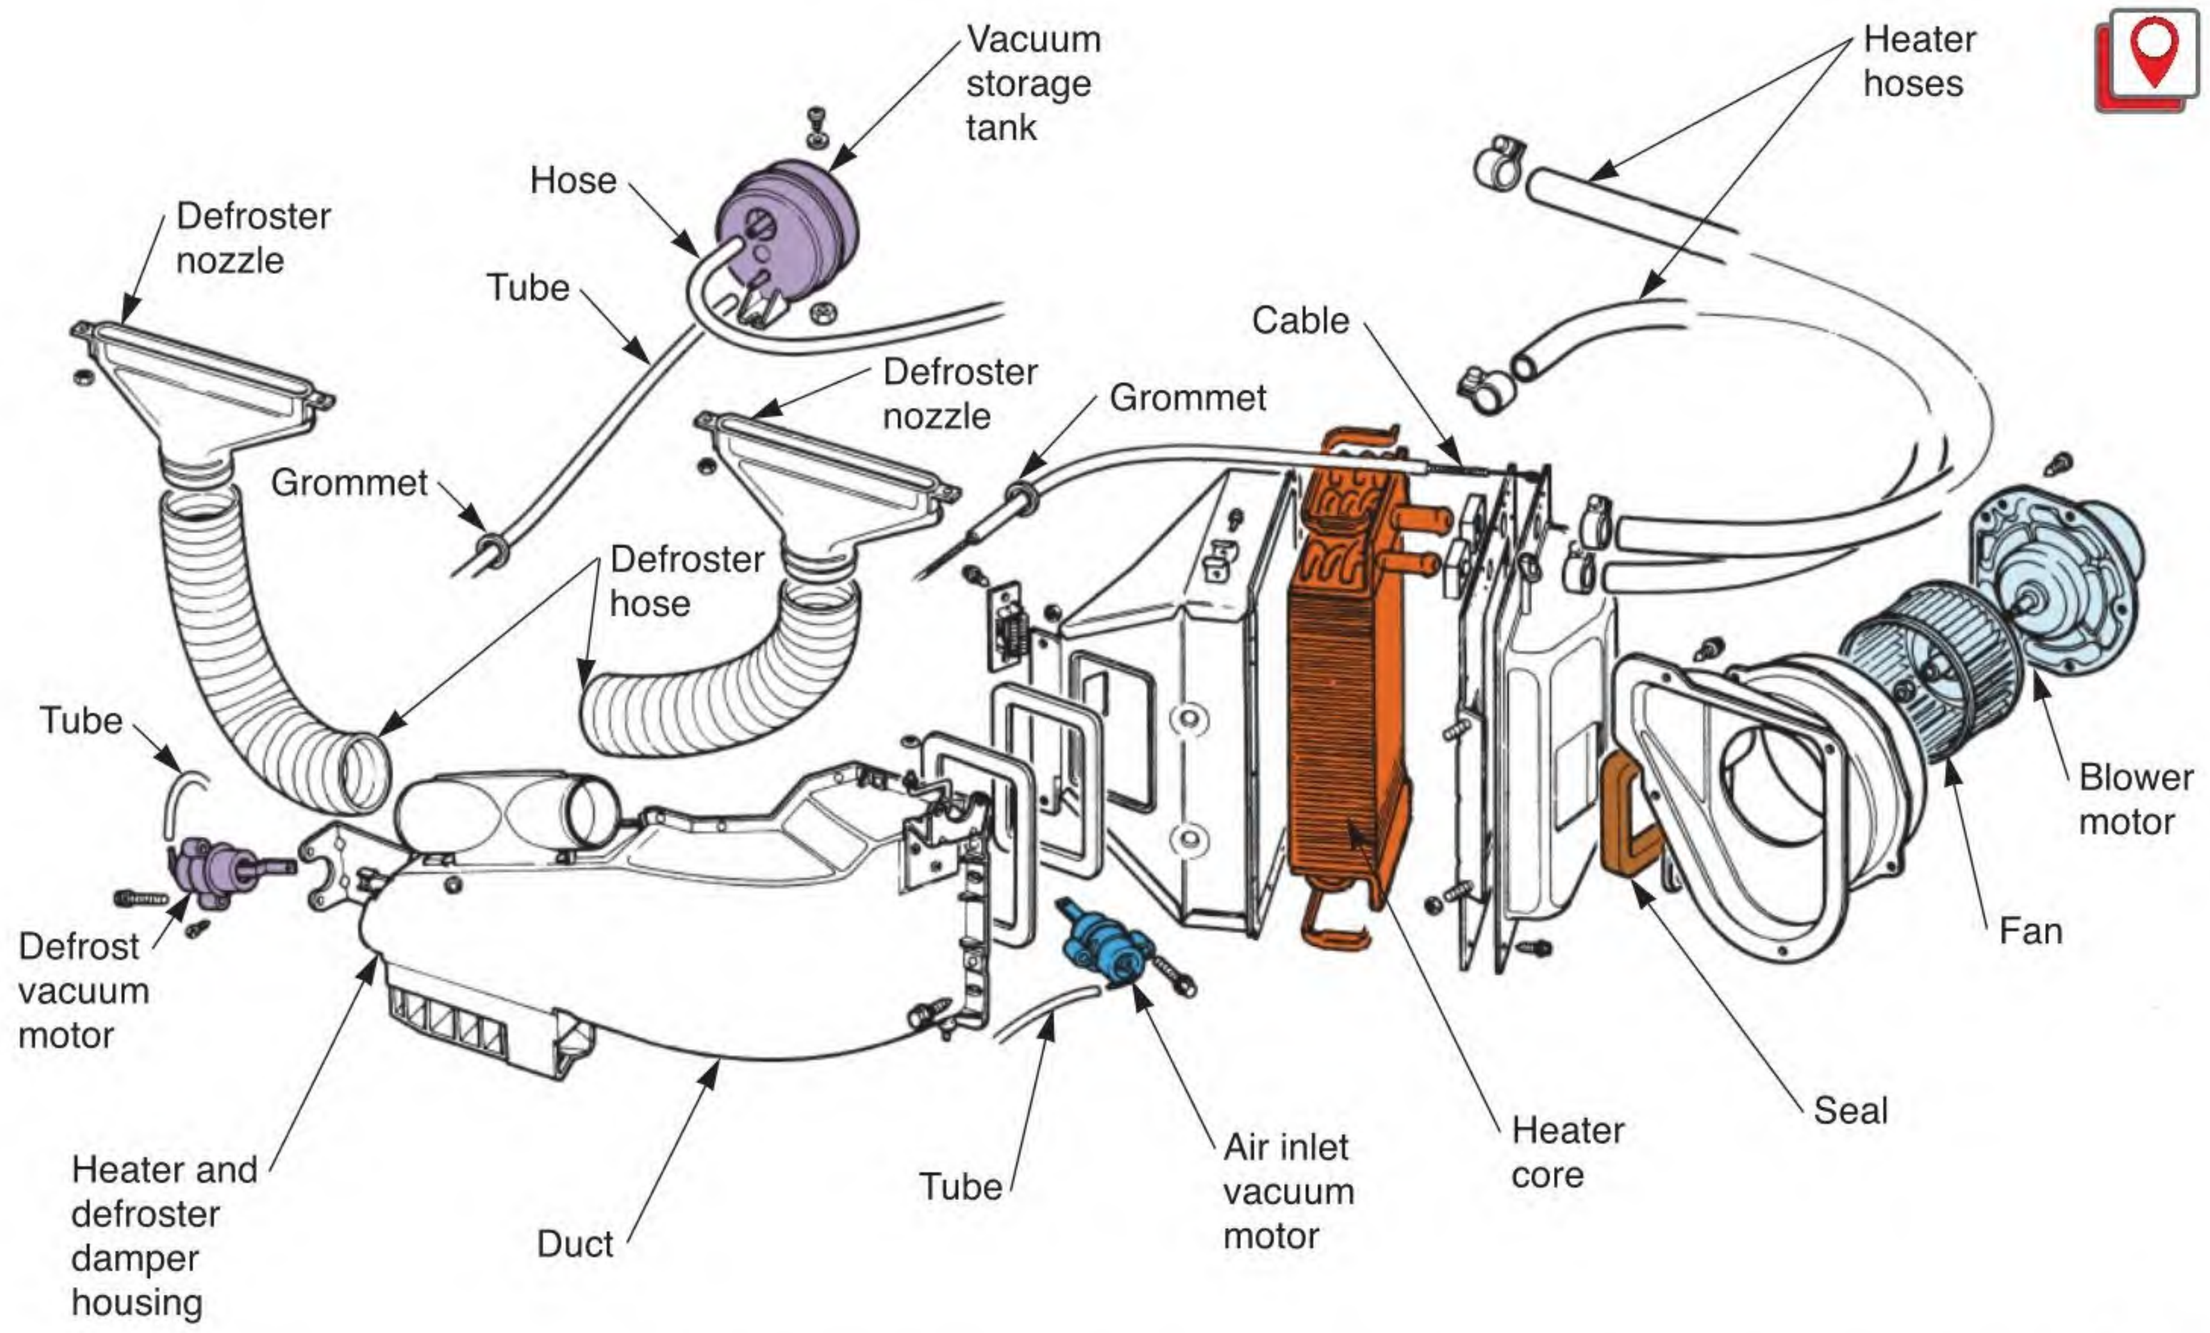
The service valves on older vehicles are different from those used on new vehicles. This helps prevent the accidental use of the wrong type of refrigerant (R-12 instead of R-134a).

Heating System

The heating system uses the engine's cooling system heat to warm the passenger compartment in cold weather. A heating system typically consists of two heater hoses, a heater core, a blower (fan), and a control mechanism. See **Figure 83-29**.

Heater hoses are small-diameter hoses that carry engine coolant to the heater core. Hot engine coolant flows through one heater hose, through the heater core, and back into the engine through another heater hose. A vacuum-operated valve may be used in one of the heater hoses to control coolant flow to the heater core.

The ***heater core*** is a small, radiator-like unit that provides a large surface area for heat dissipation into the passenger compartment. It is made of a series of tubes surrounded by fins. As air passes through the tubes and fins, heat is transferred into the air.



The ***blower*** is an electric motor and fan assembly. When current is fed to the electric motor, the fan spins to force air through the heater core or the air conditioning evaporator. The blower mounts in a housing that surrounds the heater core, the evaporator (if used), and the air doors.

Heater controls can be set to move the duct flaps so that cool outside air is mixed with hot heater core air. This permits control of the passenger compartment temperature, **Figure 83-30**.

Heating and Air Conditioning Controls

The driver uses levers, buttons, or switches in the instrument panel to control the operation of the heating and air conditioning systems. When the driver activates one of the instrument panel controls, one of four methods may be used to operate the system components:

- An electric switch may operate (usually through relays) the blower motor, the compressor clutch, and other electric components.

Chrysler

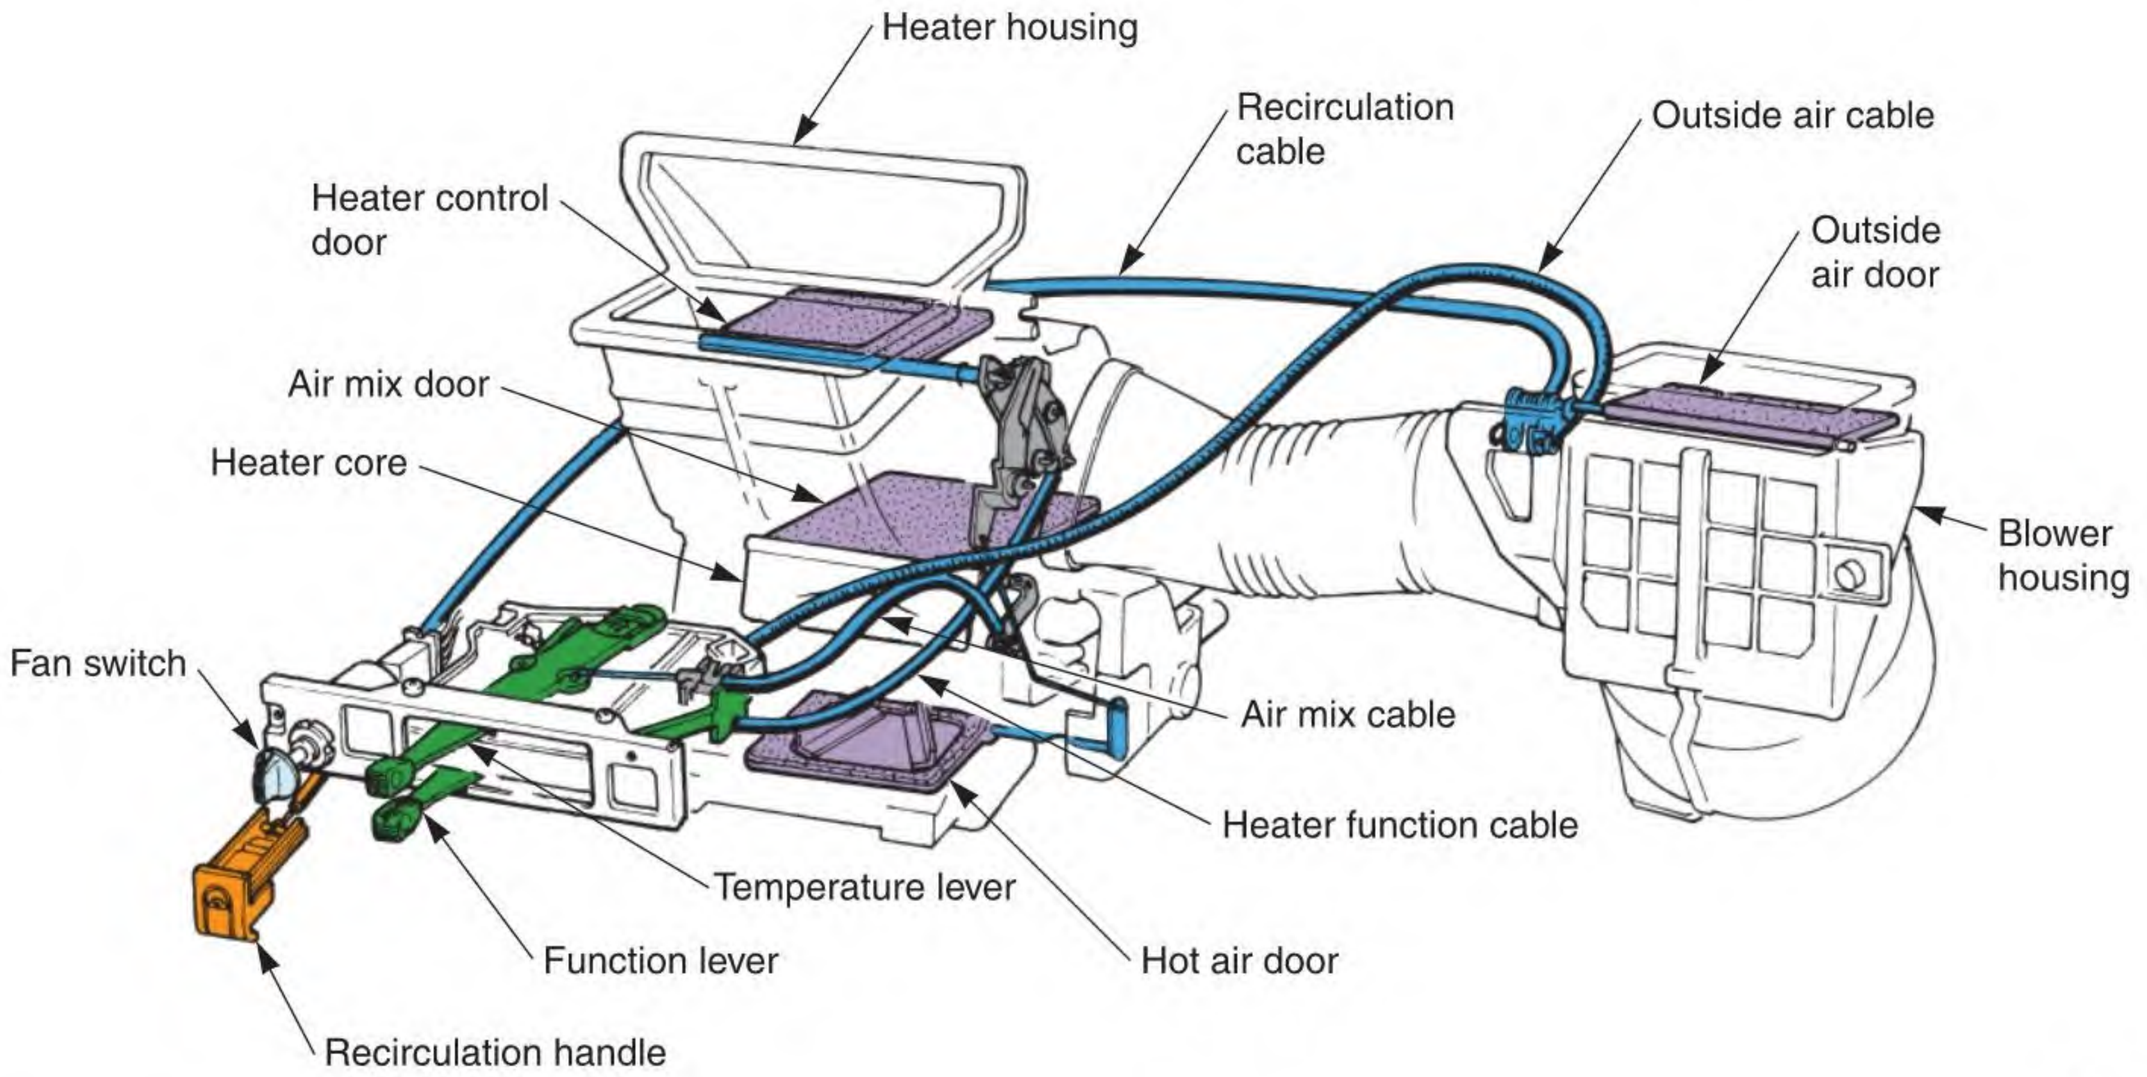
Figure 83-29. Exploded view of vent and heat components that mount under the dash of a car. Note the vacuum motors, the heater core, and the blower.

- Mechanical levers and cables can operate air doors (air flaps) over the heater core, evaporator, and ducts.
- A vacuum switch can operate vacuum motors (vacuum diaphragms) that open and close the air doors.
- An electronic control unit (computer) and sensors can operate the heating and air conditioning systems automatically.

Manual Temperature Control

Manual controls for the heating and air conditioning systems are driver controlled. The driver must select the blower speed and air door positions to control the heating or cooling temperatures.

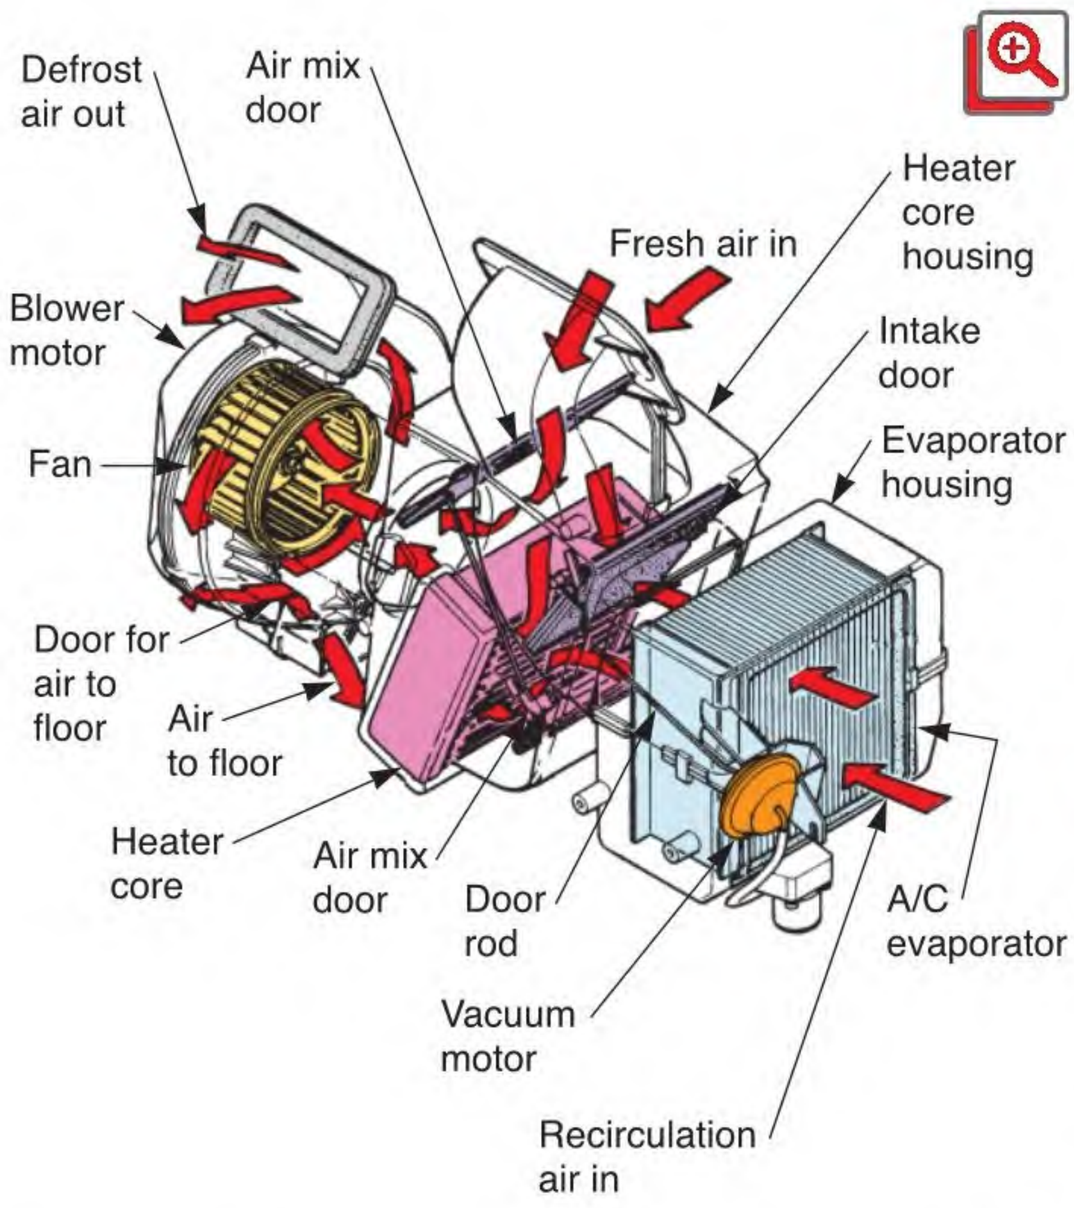
Push-pull cables use a stiff steel cable that slides back and forth in its housing. This design, after prolonged service, tends to bind when pushed. A ***pull-pull cable*** loops cable in its housing so that it always pulls when activated. Like a movable clothesline, turning the dash knob pulls the cable in both directions for smoother operation. A typical cable-type manual control for a heater is shown in **Figure 83-30**.



A manual control system can also use ***vacuum motors*** (sealed rubber diaphragms) to operate the air doors. If used, the control panel will contain a ***vacuum switch*** to route engine vacuum to the correct vacuum motor. The vacuum motors then move the air doors.

Figure 83-31 shows how air can be mixed to control the temperature of the air entering the passenger compartment.

Automatic Temperature Control



Automatic temperature control systems use various pressure and temperature sensors and a control module (computer) to maintain a preset passenger compartment temperature. See **Figure 83-32**. The driver sets the instrument panel controls to a specified temperature; then the heating and air conditioning systems automatically keep the vehicle's passenger compartment at this temperature.

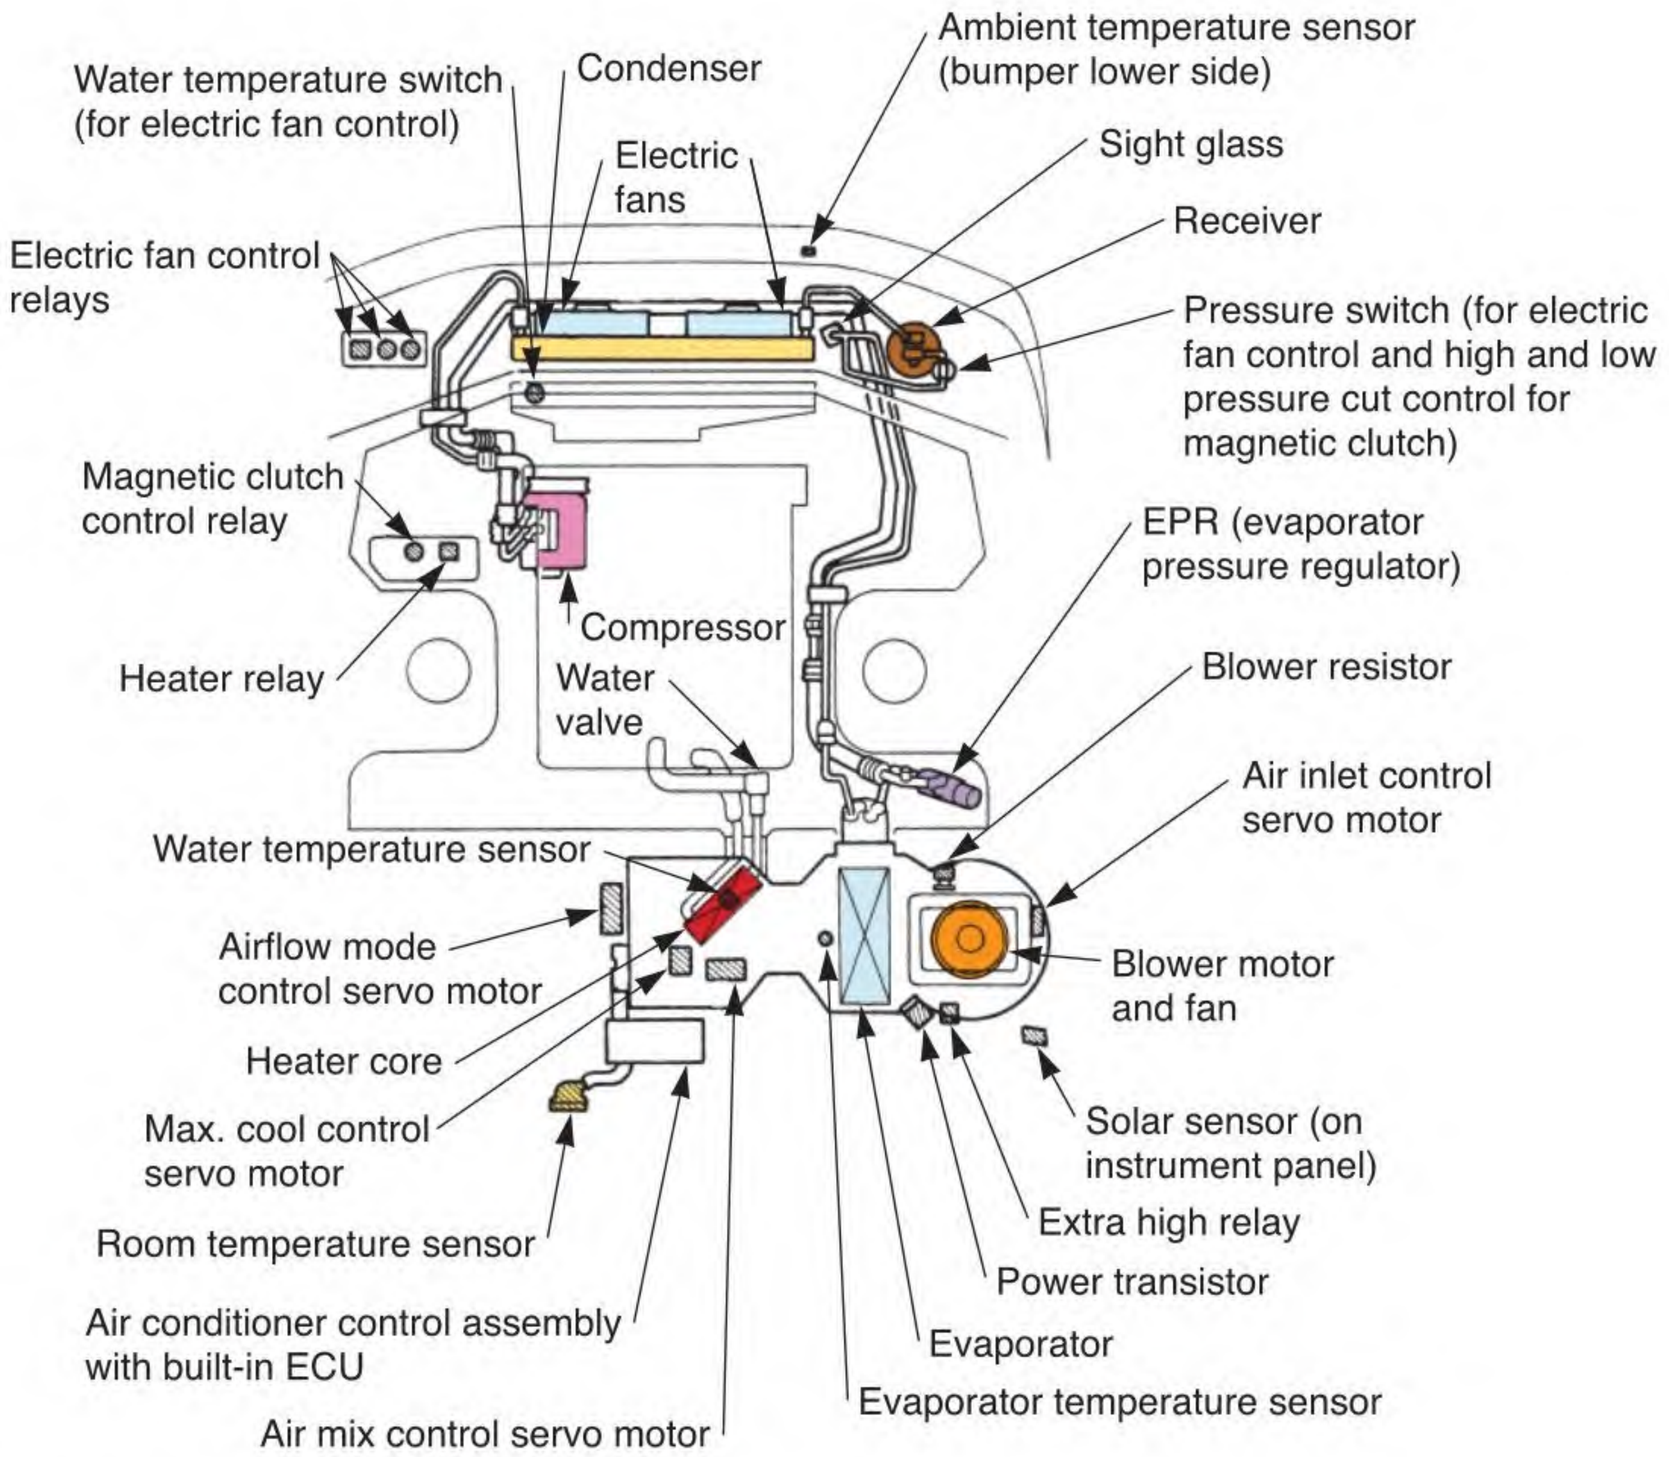
Honda

Figure 83-30. Driver's dash levers can be moved to operate cables to the air control doors. Doors then open or close the ducts to route warmed or cooled air to the passenger compartment.

Nissan

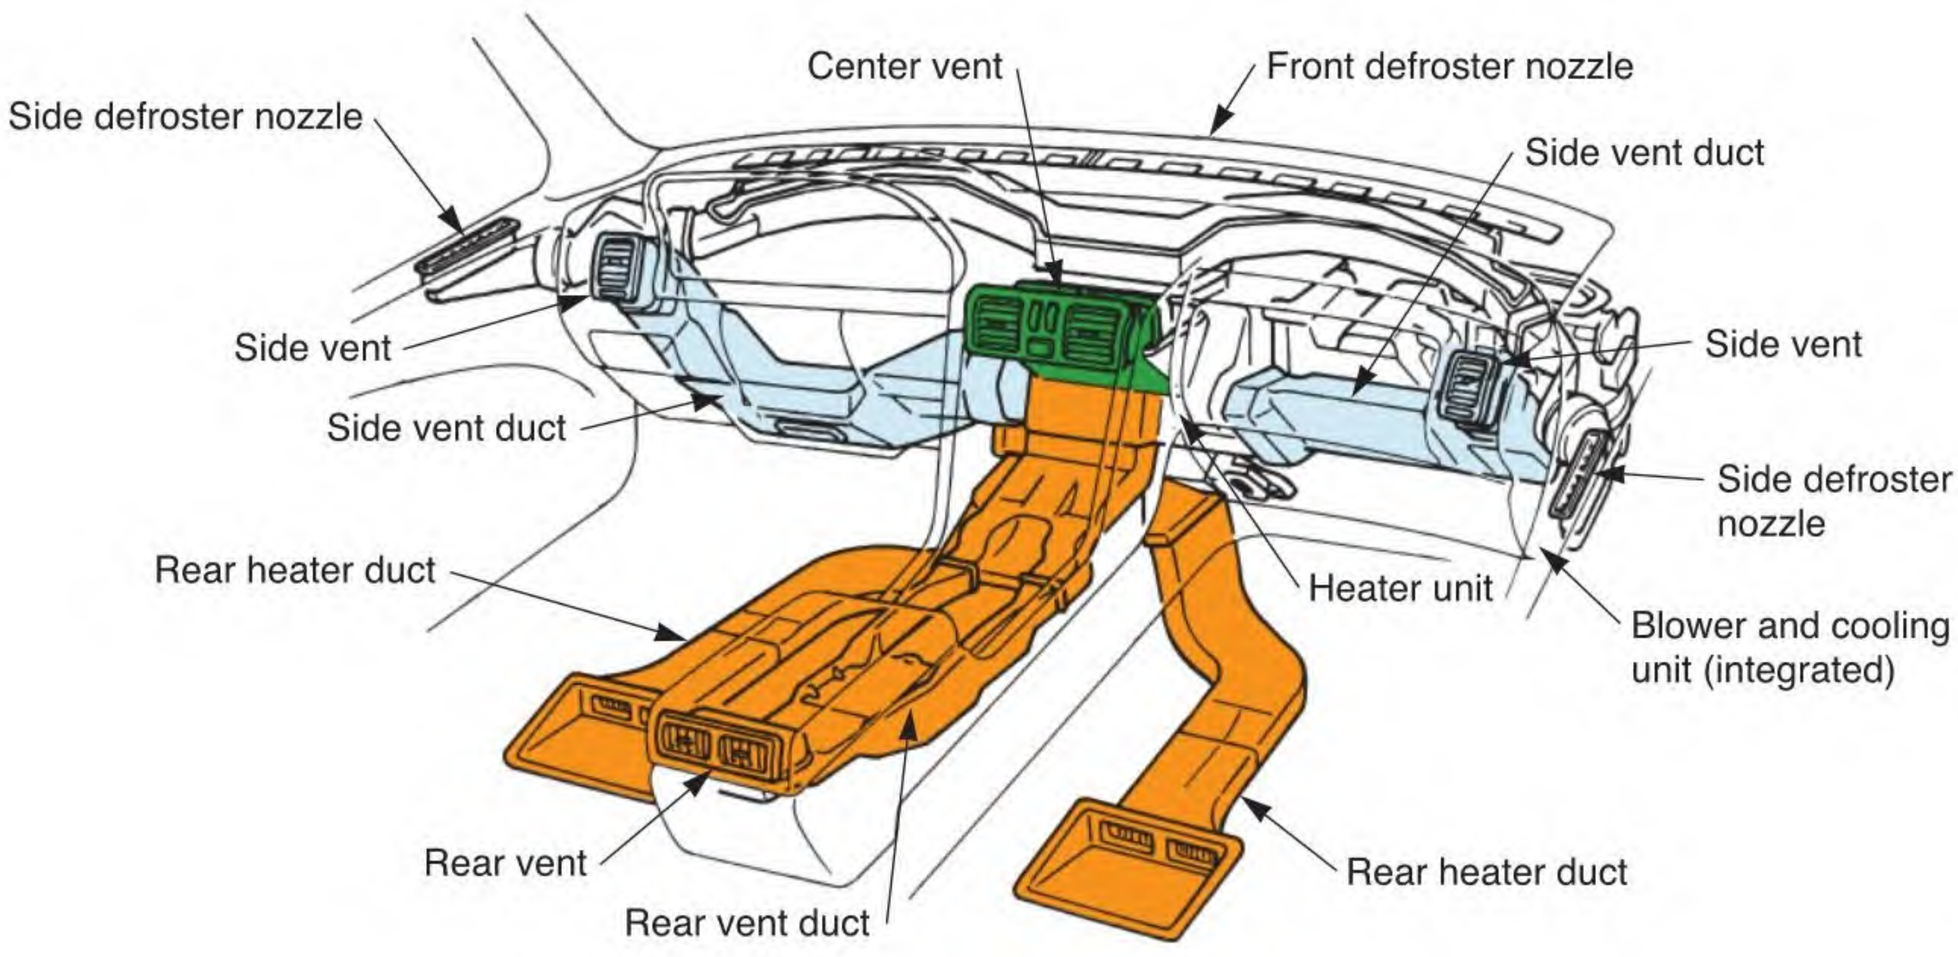
Figure 83-31. Trace the airflow through the heater core and air conditioning evaporator. Hot and cold air blend when needed to maintain a comfortable temperature output.



An automatic temperature control system can use three temperature sensors: an in-car sensor, a duct sensor, and an ambient (outside) air sensor. These temperature sensors may be thermistors. A ***thermistor*** is an electrical device that changes resistance with a change in temperature. For example, the in-car sensor's (thermistor's) internal resistance may drop when the passenger compartment temperature drops. The increased current flow could be used by the electronic control unit to turn on the heater or to turn off the air conditioning system. In this way, the system maintains the preset temperature.

Ducts and Vents

Ducts are plastic tubes of various shapes that carry air over the evaporator and the heater core, as well as to the vents. See **Figure 83-33**.



Air blows into the passenger compartment through ***vents*** (louvered openings). Adjustable grills are provided to open and close the vents and to change the direction of airflow.

Passenger Compartment Filters

Some climate control systems use a ***high-efficiency air filter*** to clean the air entering the passenger compartment. This filter helps people with allergies by trapping pollen and other particles in the air.

Electronic air filters use electrically-produced ion action to help remove small particles, such as dust and pollen, from the air entering the passenger compartment. An electrically-charged, plastic micron filter traps particles as small as 5 microns (0.0002″ or 0.005 mm). The electrical charge (ion action) on the polyester-polycarbonate plastic filter causes these microscopic particles to stick to the surfaces of the element and not enter the passenger area through the climate control system.

Solar Ventilation

A ***solar ventilation system*** uses energy from sunlight to operate the blower. The major parts of a solar ventilation system include:

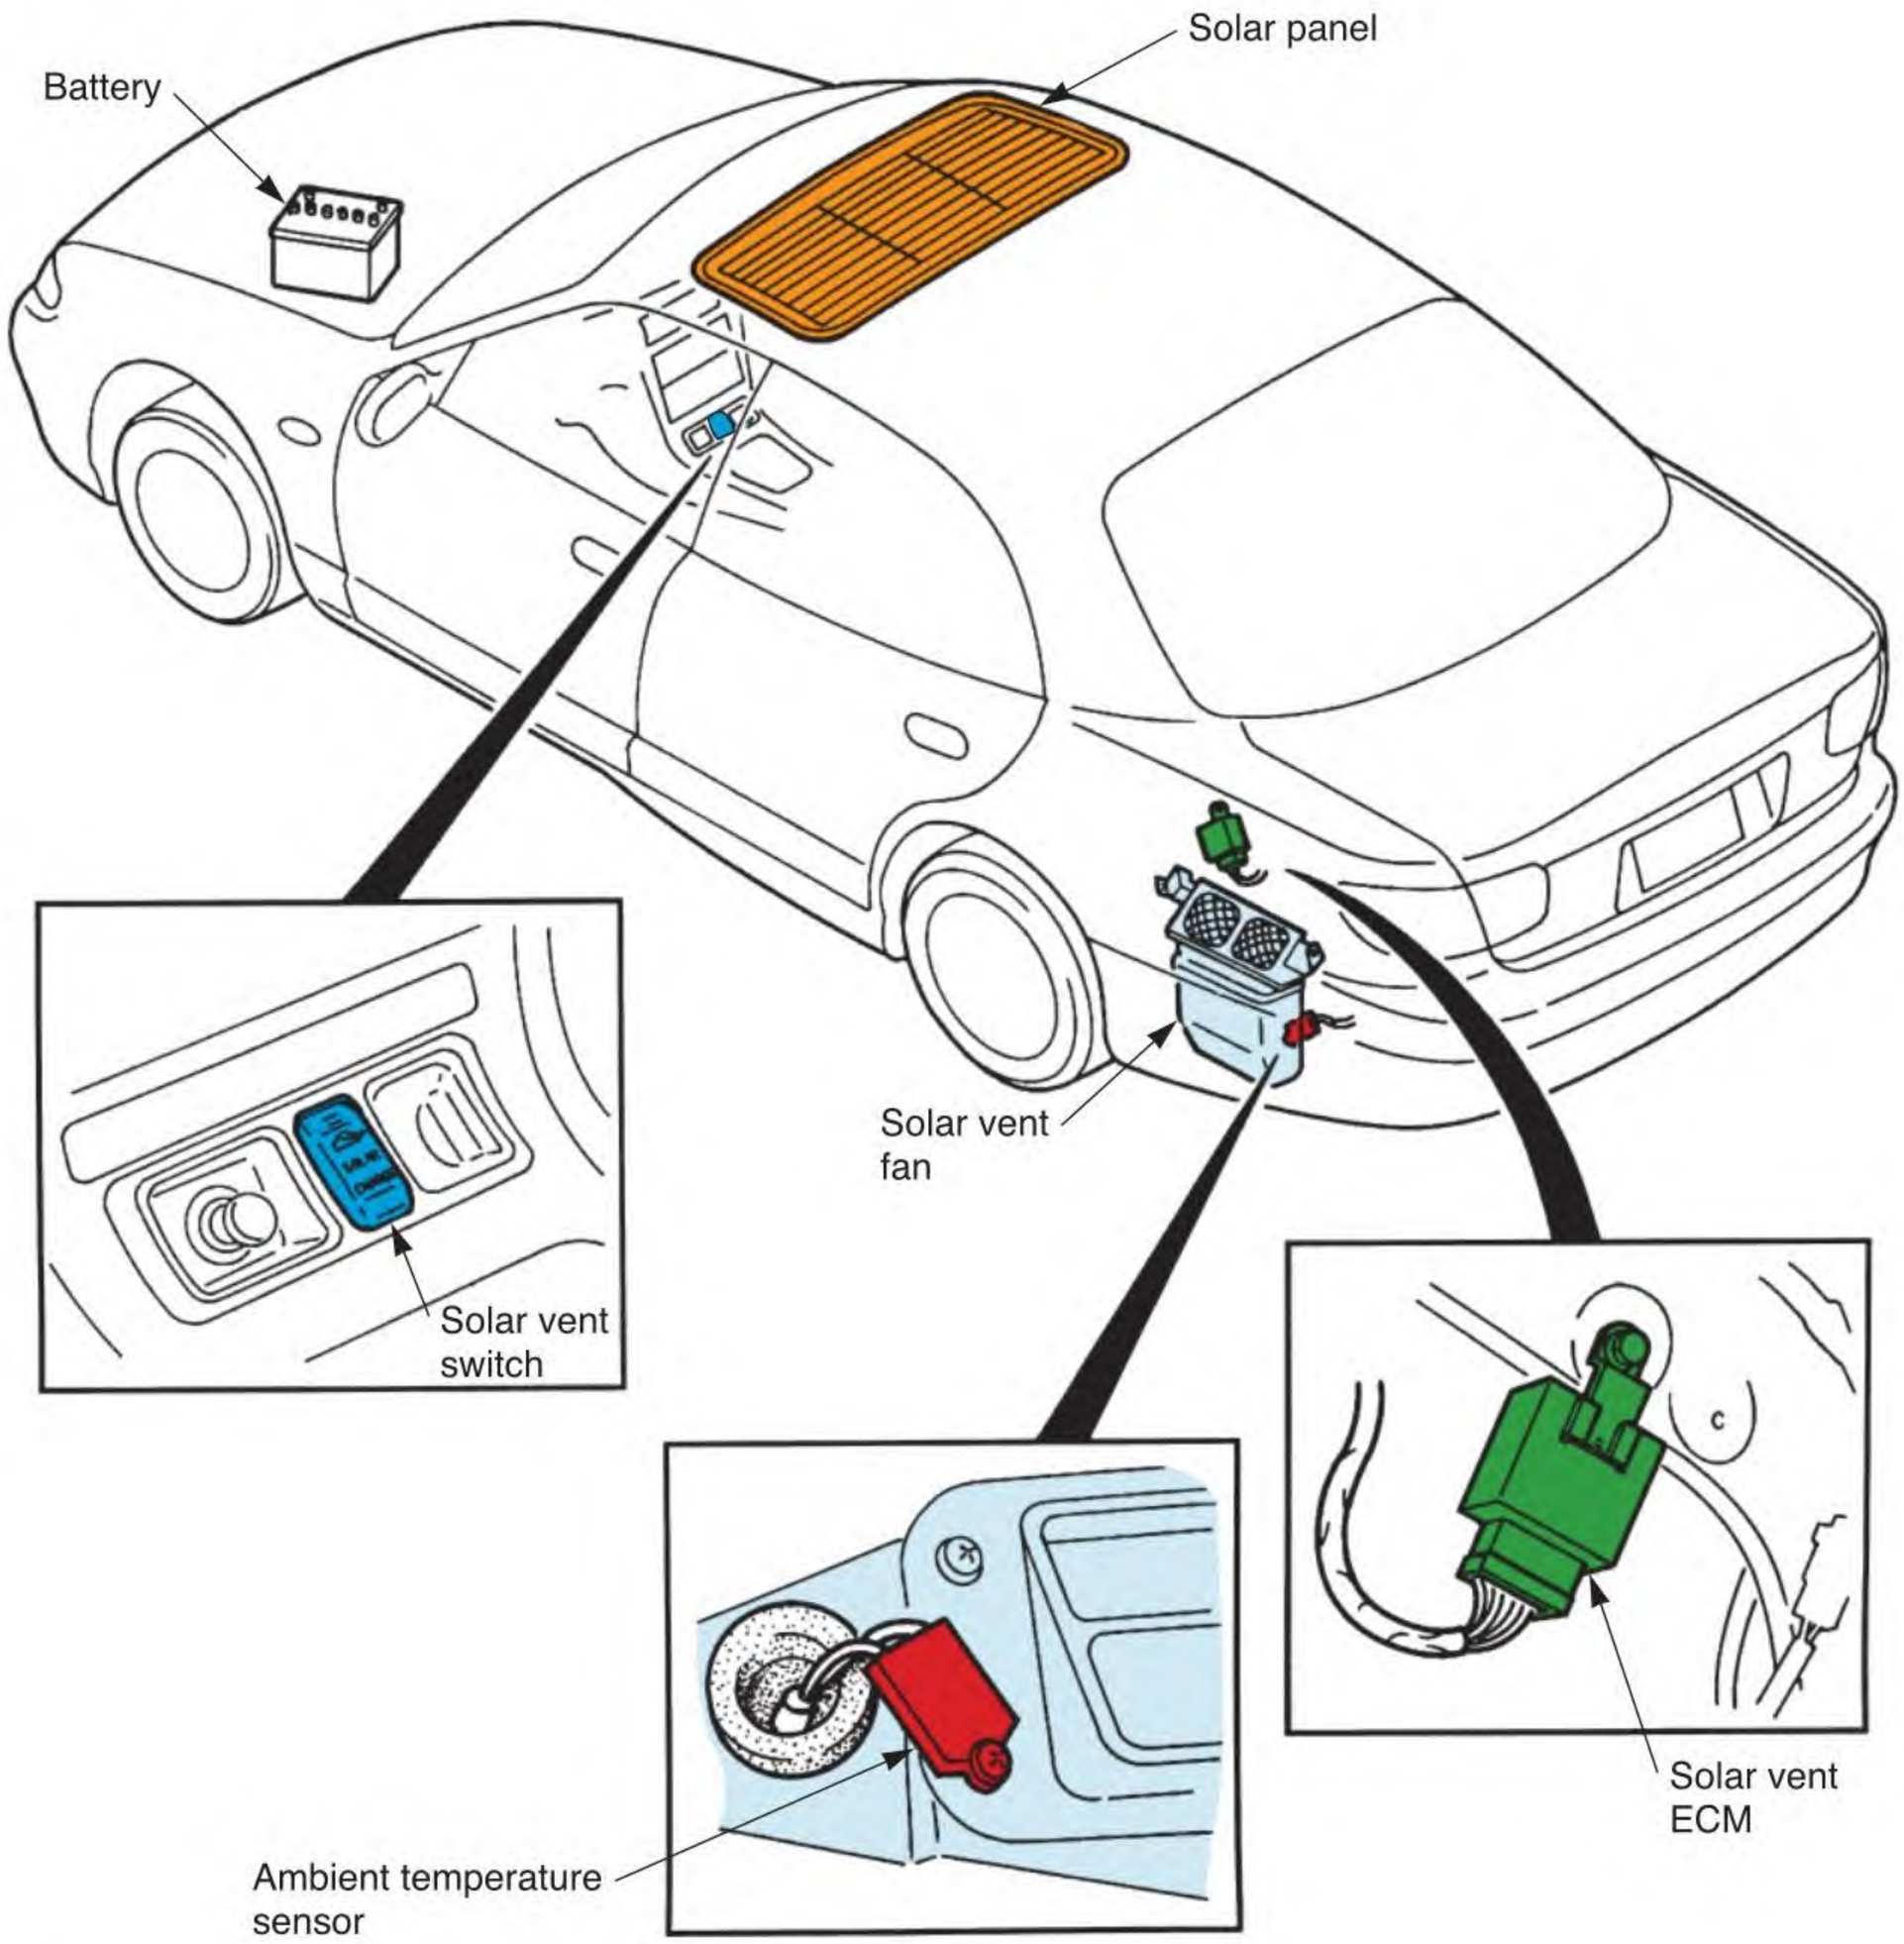
- ***Solar ventilation switch***—The solar ventilation switch allows the system to be manually turned on and off.
- ***Ambient temperature switch***—The temperature switch turns the blower on if the interior temperature is high enough.
- ***Ventilation fan***—A small, low power consumption fan circulates outside air through the interior.
- ***Solar cell***—The solar cell is a solar panel that converts sunlight into electricity.
- ***Solar ventilation ECM***—A small computer monitors and controls the operation of the solar ventilation system.

The solar cell is usually located in the roof or the moon roof of the vehicle. The solar cell converts sunlight directly into electrical energy, which is used to operate the blower. The blower circulates cool air to lower the temperature in the passenger compartment in hot weather. The solar cell can also be used to recharge the battery if needed. See **Figure 83-34**.

Hybrid Systems

In some hybrid vehicles, the gasoline engine powers the air conditioning compressor. This makes it difficult for the air conditioning system in these vehicles to maintain a constant temperature because the compressor stops turning when the gasoline engine shuts down—during stops or during all-electric operation. However, switching to the maximum A/C setting keeps the engine running at all times for efficient cooling.

On many hybrid vehicles, the compressor is turned by an electric motor powered by the battery pack. Therefore, the compressor operates even when the gasoline engine is off.



Green Tech

Aerosol Spray Cans

Aerosol spray cans may be used in various areas of automotive repair, such as paint touch-ups or for cleaning. Many aerosol sprays use chlorinated compounds, which emit volatile organic compounds (VOCs) into the atmosphere. Another concern with aerosol spray cans is the product contained within. When disposing of these cans, they must be completely empty or they can be considered hazardous waste. The containers themselves pose a threat to the environment if they are not recycled. To combat the dangers caused by aerosol spray cans, green shops can use water-based products over chlorinated products. To help reduce the amount of empty cans produced, use refillable spray bottles for aqueous solutions.

Summary

- The term *air conditioning* generally means to control the temperature, humidity, and flow of air in the passenger compartment.
- There are three basic states of matter: vapor, liquid, and solid.
- Conduction is heat transfer through objects that are touching each other.
- Convection is heat transfer caused by the air surrounding objects.
- Radiation is carried out by infrared rays.
- Cold is actually an absence of heat.
- The British thermal unit, abbreviated Btu, is the unit of measurement for heat transfer from one object to another.
- Condensation occurs when a vapor changes into a liquid.
- A refrigerant is a substance with a very low boiling point. It is circulated through a refrigeration, or air conditioning, system.
- R-134a is currently being used because it is less damaging to the ozone layer than R-12.
- The high side, or discharge side, of an A/C system consists of the parts between the output of the compressor and the flow-control restriction.
- The low side, or suction side, of an A/C system consists of the parts between the flow-control restriction and the inlet of the compressor.
- An air conditioning compressor is a refrigerant pump that is bolted to the front of the engine.
- A reed valve is simply a thin piece of metal that bends to open and close an opening.
- A magnetic clutch is used to engage and disengage the air conditioning system compressor.
- Refrigerant oil is a high-viscosity, highly refined (pure) oil used to keep the parts of the air conditioning system lubricated.
- An air conditioning condenser is a radiator-like device that transfers heat from the refrigerant to the outside air.
- A receiver-drier removes moisture from the system and stores extra refrigerant.
- The evaporator, like the condenser, is a refrigerant coil mounted in cooling fins.
- The expansion tube, or orifice tube, has a fixed opening that meters the amount of refrigerant flowing into the evaporator.
- An expansion valve is a temperature-sensitive valve that controls refrigerant flow and the evaporator temperature.
- The heating system uses the engine's cooling system heat to warm the passenger compartment in cold weather.
- The heater core is a small, radiator-like unit that provides a large surface area for heat dissipation into the passenger compartment.
- Automatic temperature control systems use temperature sensors and a control module (computer) to maintain a preset passenger compartment temperature.
- Ducts are plastic tubes of various shapes that carry air over the evaporator, the heater core, and the vents.
- The vents are the louvered openings where air blows into the passenger compartments.
- Some climate control systems use a high-efficiency air filter to clean the air entering the passenger compartment.
- A solar ventilation system uses energy from sunlight to operate the blower.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

Activities

1. Make a sketch (by hand or using a computer graphics/drawing program) of a basic refrigeration system. Create a presentation from your sketch and use it to explain the refrigeration cycle to the class.
2. Obtain a junked automotive air conditioning compressor and disassemble it. Identify the type of compressor and the basic parts. Then, reassemble the compressor.
3. Research R-12 and other CFC refrigerants to find out why they are dangerous to the environment. Write a short report (1–2 pages) on the problem and the action being taken to solve it.
4. Demonstrate the procedure for removing and installing the passenger compartment filter, or cabin filter, on a vehicle of your choice. Inspect the filter and, if possible, determine when it was last replaced. Discuss with your classmates the issues caused by neglecting to change the cabin filter according to the vehicle manufacturer's recommendations.

Review Questions

Answer the following questions using the information provided in this chapter.

1. The three basic states of matter are _____, _____, and _____.
2. Explain the three methods of heat transfer.
3. Heat always moves from the colder object to the warmer object. True or False?
4. What is a Btu?
5. _____, the opposite of _____, occurs when a vapor changes back into a liquid.
6. This substance circulates inside an air conditioning system.
   (A) Refrigerant.
   (B) R-12.
   (C) R-134a.
   (D) All of the above.
7. List and explain the eight basic parts of a refrigeration system.
8. Which of the following is *not* a function of an air conditioning system?
   (A) Cools air.
   (B) Circulates air.
   (C) Humidifies air.
   (D) Cleans air.
9. Describe the high and low side of an air conditioning system.
10. How does an air conditioning compressor turn on and off?
11. Name the five types of air conditioning compressors.
12. _____ _____ is used in the A/C system to keep the compressor lubricated.
13. How does the expansion tube A/C system control output temperature?
14. How does the thermostatic expansion valve A/C system control outlet temperature?

Copyright Goodheart-Willcox Co., Inc.

15. Why are service valves provided?
16. The suction service valve is located at the inlet to the compressor, in the system low side. True or False?
17. The _____ _____ is a small radiator-like device that provides a large surface area for heat dissipation into the passenger compartment.
18. Explain four methods used to operate heater components.
19. Define the term *thermistor*.
20. How does a solar ventilation system work?

ASE-Type Questions

1. Technician A says the operating principles of an automotive air conditioning system are completely different than those of a home refrigerator. Technician B says an automotive air conditioning system operates on the same principles as a home refrigerator. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says vapor is one of the basic states of matter. Technician B says a molecule is one of the basic states of matter. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says "conduction" is heat transfer through objects that are touching each other. Technician B says "conduction" is heat transfer caused by the air surrounding objects. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says heat always transfers from a hotter object to a colder object. Technician B says heat always transfers from a colder object to a hotter object. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says "evaporation" normally refers to a liquid changing into a vapor state. Technician B says "evaporation" normally refers to a vapor changing into a solid. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says "condensation" occurs when liquid changes back into a vapor. Technician B says "condensation" occurs when a vapor changes back into a liquid. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says when pressure is placed on a substance, the temperature of the substance increases. Technician B says when pressure is placed on a substance, the temperature of the substance decreases. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says a "refrigerant" is a substance with a very low boiling point. Technician B says a "refrigerant" is a substance with a very high boiling point. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says the refrigerant R-134a has been found dangerous to the environment and its production was ceased in 1995. Technician B says the refrigerant R-12 has been found dangerous to the environment and its production was phased out. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says in a basic refrigeration cycle, the refrigerant goes through a compression phase. Technician B says in a basic refrigeration cycle, the refrigerant goes through a vaporization phase. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

11. Technician A says an automotive air conditioner's condenser causes refrigerant to change from a gaseous state into a liquid state. Technician B says an automotive air conditioner's condenser causes refrigerant to change from a liquid state into a gaseous state. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. Technician A says the "high side" of an automotive air conditioning system is known as the "discharge side." Technician B says the "high side" of an automotive air conditioning system is known as the "suction side." Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. Technician A says a "crank-type" compressor is used on certain automotive air conditioning systems. Technician B says a "rotary vane type" compressor is used on several automotive air conditioning systems. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. Technician A says an automotive air conditioner's accumulator forces air through the evaporator and into the passenger compartment. Technician B says an automotive air conditioner's accumulator keeps liquid refrigerant from entering the compressor. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
15. All of the following are basic components of an automotive heating system, *except:*
    (A) blower.
    (B) heater core.
    (C) receiver-drier.
    (D) ducts.

Chapter 84
Heating and Air Conditioning Diagnosis, Service, and Repair

After studying this chapter, you will be able to:

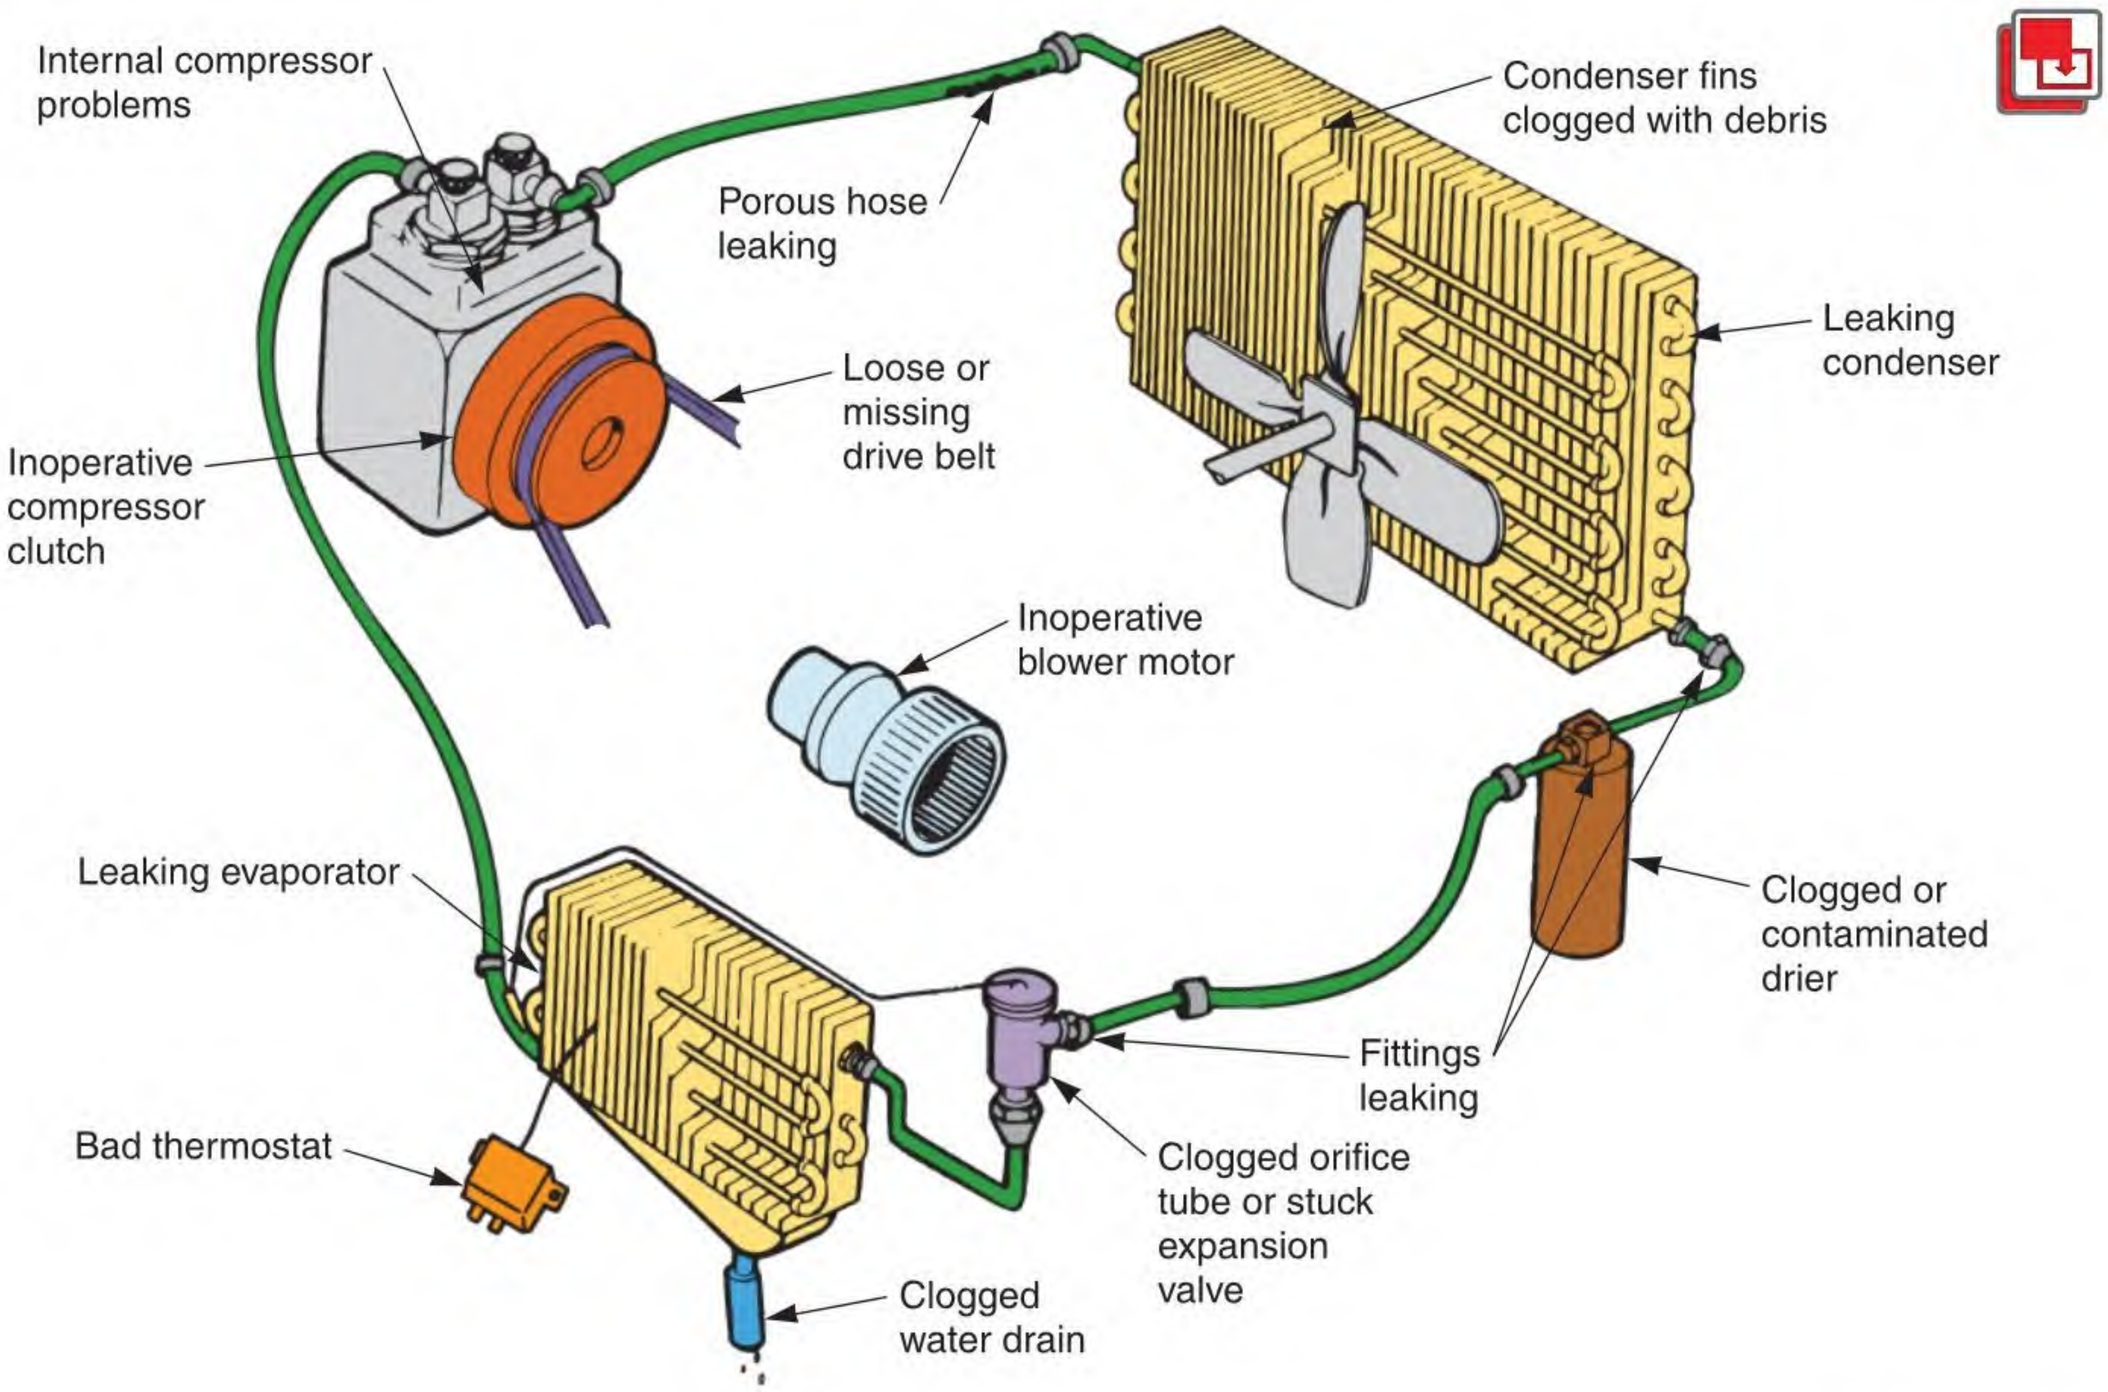
- Visually inspect a heating and air conditioning system and locate obvious troubles.
- Diagnose common heating and air conditioning problems.
- Describe the functions and uses of air conditioning test equipment.
- Locate air conditioning and heating system leaks.
- Explain how to replace major heating and air conditioning components.
- Describe the general procedures for evacuating and charging an air conditioning system.
- Demonstrate safe working practices when servicing heating and air conditioning equipment.
- Correctly answer ASE certification test questions about the diagnosis and repair of heating and air conditioning systems.

Heating and air conditioning systems are prone to failure. Even the smallest leak (refrigerant or coolant) will eventually prevent either system from working properly. As you will learn, correct service methods not only keep the vehicle operating normally, but also help protect our environment from damage caused by refrigerant gases and antifreeze spillage.

Inspecting an Air Conditioning System

When an air conditioning system does not cool properly, visually inspect the entire system. Look for obvious signs of trouble, including:

- Loose or missing compressor drive belt.
- Inoperative compressor clutch.
- Disconnected or damaged wiring or vacuum hoses.
- Refrigerant leaks (wetness) around lines or fittings.
- Blockage (leaves, mud) in the condenser fins.
- Inoperative air control doors.



Some common air conditioning system problems are illustrated in **Figure 84-1**.

Scanning the A/C System

Late-model climate control systems produce trouble codes if the on-board diagnostic system detects an abnormal circuit value or condition. If the indicator light in the dashboard glows, connect a scan tool to the vehicle. The scan tool might indicate problems with air conditioning system circuits and components, such as:

- Radiator fan circuit
- A/C clutch circuit

Copyright Goodheart-Willcox Co., Inc.

Florida Dept. of Voc. Ed.

Figure 84-1. Note the types of problems that develop in a typical air conditioning system.

- A/C pressure circuit (low, high, or out of range)
- Outside temperature sensor circuit
- Interior temperature circuit
- Solar sensor circuit
- Blower motor circuit
- A/C high side and low side temperature sensors
- Compressor relay circuit
- Airflow control circuit
- Control head circuit
- Climate control ECM

Modern OBD systems monitor almost every circuit in a climate control system, which makes the task of troubleshooting very efficient.

Checking Line Temperatures

To check the basic action of an A/C system, start the engine. Turn the air conditioning system on high and allow it to run for about ten minutes. Feel the refrigerant lines or aim a laser thermometer at both high- and low-pressure lines to check their temperatures.

The *high-side* (discharge) line should be warm or hot. The *low-side* (suction) line should be cool. If this is the case, you know that refrigerant is moving through the system.

When the low-side line is cold but the system does *not* cool the passenger compartment, there might be a problem with the air control doors or the instrument panel controls.

If the high-side line is *not* warm and the low-side line is *not* cold, a problem exists in the refrigeration section of the system. You must perform other tests to pinpoint the problem source.

Inspecting the Sight Glass

Check the air conditioning system sight glass (if used) during your visual inspection of the system. It can give you information on the condition of the

Copyright Goodheart-Willcox Co., Inc.

system. The sight glass may be located in the top of the receiver-drier or in a refrigerant line. **Figure 84-2** shows how to read an A/C system sight glass.

A ***clear sight glass*** usually indicates that the A/C system has the correct charge of refrigerant. However, it can also indicate an empty system. If the low-side line is cool, there is refrigerant in the system. If the sight glass is clear and the low-side line is warm, the system could have a refrigerant leak.

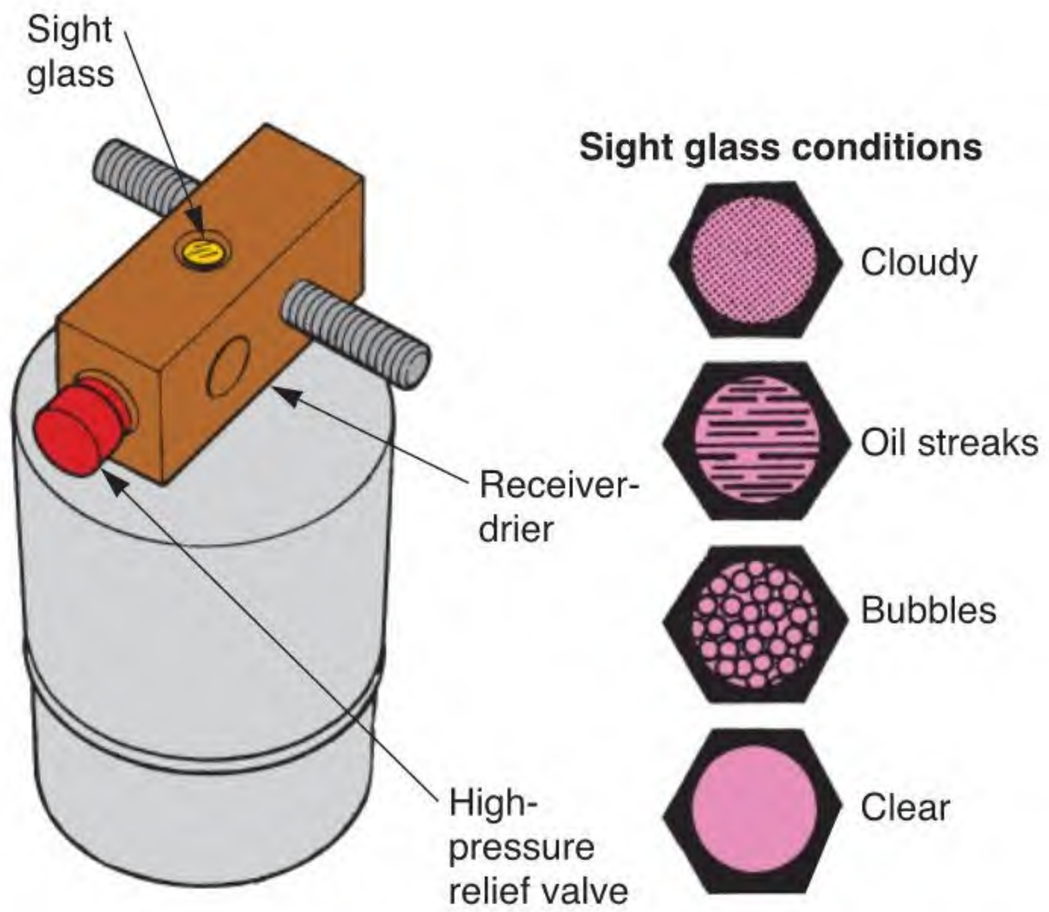
A ***bubbling sight glass*** indicates that the A/C system is low on refrigerant and air is in the system. However, an occasional bubble during clutch cycling or system start-up may be normal.

An ***oil-streaked sight glass*** denotes a low refrigerant level. In this case, excessive compressor oil is circulating through the system.

A ***cloudy sight glass*** may indicate that the desiccant (drying agent) in the receiver-drier or the accumulator has broken down and is circulating through the system. You probably need to replace the unit or the desiccant bag.

Sight glass readings can be used only as indicators of system problems. They are not totally accurate. You must perform other tests to verify problems.

Refrigerant Safety Precautions



To avoid injury, observe the following safety precautions when working with refrigerant:

- Refrigerant can cause severe *frostbite* if it contacts your skin. Be careful when opening a line in the air conditioning system. Place a rag around the fitting before loosening the connection.
- Always wear safety glasses when working with refrigerant—it can cause *blindness* if it sprays into your eyes. If refrigerant sprays into your eyes, flush them with water, without rubbing. Always consult a doctor.
- Store refrigerants away from excessive heat. Pressure in a refrigerant container increases as temperature rises. High heat could make the tank explode, shooting metal fragments and refrigerant into your face or hands. Store refrigerant at temperatures below 104°F (40°C).
- Keep refrigerant away from an open flame. When burned, refrigerant turns into phosgene gas, a highly *toxic poison*. When using a torch-type leak detector, carefully follow directions and make sure the work area is well ventilated.
- Never discharge refrigerant into the air. To prevent environmental damage, all refrigerant must be reclaimed or recycled. Also, discharging any vapor in a confined space, where it could displace air, may cause *suffocation*.
- Improper refrigerant storage poses a danger to those working in the shop and to the environment. In addition to causing physical injury such as frostbite, refrigerants allowed to escape from storage containers can damage the Earth's ozone layer.
- Refrigerants should be stored in approved containers that are in good condition. Replace containers exhibiting signs of corrosion or damage. If a container is designed to accept a safety cap, secure the cap when the container is not in use.
- Store refrigerant containers in a location away from mechanical work so they are not accidentally damaged during vehicle repair operations. Accidentally striking or knocking over a container could cause the release of refrigerant into the atmosphere.

R-134a Service Differences

R-134a refrigerant systems require the use of special tools, fittings, and service procedures. See **Figure 84-3**.

- Never use a flammable refrigerant, like OZ-12, in a system designed for R-134a or R-12. If a crash or collision occurs, this type refrigerant could catch fire and kill someone.

Chrysler

Figure 84-2. If used, inspect the sight glass. It will indicate the condition of the A/C system. The sight glass may be in the top of the receiver-drier or in the line.

Service Tools			
Part/tool	**R–12 system**	**R–134a system**	**Remarks**
Tool joints	Inch threads	Metric threads	Threads standards for tool joints have been changed to avoid confusing R-12 system tools with R-134a system tools.
Charging valve joints	Screw-on type HI: 3/8–24 UNF LO: 7/16–20 UNF	Quick-connect–type HI: 16 mm (0.6 in) dia. LO: 13 mm (0.5 in) dia.	The shape of the charging valve joints differ for each system to avoid confusion. The quick-connect–type charging-valve joint prevents refrigerant from leaking when the charging hose is connected to the valve.
Manifold gauge	High-pressure side maximum reading: 2.9 MPa (30 kgf/cm^2, 430 psi)	High-pressure side maximum reading: 3.5 MPa (35 kgf/cm^2, 500 psi)	R-134a requires a higher pressure to condense than R-12.
Gas leak tester	Gas type Electric type	Electric type	A gas leak tester reacts with chlorine in R-12 to indicate the location of a leak. This kind of tester does not work with an R-134a system, however, because R-134a has no chlorine. Two kinds of electric testers are available: those that work exclusively with one system or the other, and those that work with both. A tester built only for R-12 systems cannot be used with R-134a systems.
Refrigerant	Chlorofluorocarbon–12 (CFC–12) (CCl_2F_2)	Hydrofluoro-carbon–134a (HFC–134a) (CH_2FCF_3)	If the refrigerants are mixed or one refrigerant is used in a system that requires the other, the compressor oil will separate from the refrigerant and not circulate within the system. This can damage the A/C compressor and cause abnormal A/C compressor vane noise. In addition, mixing R-134a with R-12 or using R-134a instead of R-12 in an R-12 system can lower the durability of the NBR O-ring and dissolve the fluorine rubber O-rings. If the fluorine rubber O-rings are dissolved, refrigerant may leak.
Compressor oil	Mineral oil	Polyalkylene glycol oil (PAG oil) (ATMOS GU10)	Special compressor oils for R-134a air conditioning systems are developed by each air conditioning vendor. Therefore, use only the specified oil for each model vehicle. If a PAG oil other than the specified type is used, the A/C compressor and refrigerant system can be damaged. If the compressor oils are mixed or one compressor oil is used in a system that requires the other, the refrigerant will separate from the compressor oil and not circulate within the system. This can damage the A/C compressor and cause abnormal A/C compressor vane noise. Mixing PAG oil with mineral oil or using PAG oil instead of mineral oil in an R-12 system can lower the durability of the NBR and fluorine rubber O-rings.
O-ring	Nitrile butadiene rubber (NBR) Fluorine rubber	High-circulated nitrile butadiene rubber (HNBR)	If an NBR O-ring is used in an R-134a system, the PAG oil and R-134a will lower the durability of the O-ring. If a fluorine rubber O-ring is used in an R-134a system, the R-134a will dissolve the O-ring and cause the refrigerant to leak.
Charging valve	Screw-on type HI: 3/8–24 UNF LO: 7/16–20 UNF	Quick-connect–type HI: 16 mm (0.6 in) dia. LO: 13 mm (0.5 in) dia.	The shape of the charging valve differs for each system to avoid confusion. The quick-connect–type charging valve prevents refrigerant from leaking when the charging hose is connected to the valve.

Mazda

Figure 84-3. Chart compares R-12 and R-134a parts and tools. Study the differences closely.

Copyright Goodheart-Willcox Co., Inc.

- The refrigerant tank for R-134a is normally blue, while R-12 is normally stored in a white tank.
- Tool fittings on R-12 systems use US Customary threads, while R-134a fittings have metric threads.
- R-134a service fittings are male, while R-12 service fittings are female.
- R-12 systems use screw-on fittings on charging valve joints; R-134a systems use quick-disconnect fittings on charging valve joints.
- Pressure gauges must read higher values when testing R-134a systems.
- Never mix R-12 and R-134a. Mixing these will make the refrigerant oil separate out of the refrigerant gas, resulting in severe compressor damage. Mixing refrigerants can also deteriorate O-ring seals and cause leakage.
- Only use the refrigerant oil recommended by the manufacturer. Like refrigerants, mixing R-12 (organic) oil and R-134a (synthetic) oil will cause separation and damage to the compressor and O-ring seals.
- Only use O-ring seals designed for the type of refrigerant and oil in the system. R-134a will dissolve the seals designed for R-12.

Imperial

Figure 84-4. A gauge set is commonly used when charging an A/C system with refrigerant gas.

Testing an Air Conditioning System

If your initial inspections and other checks do not find the source of the trouble, test the air conditioning system using pressure gauges. By comparing the high- and low-side pressures to specifications, you can determine the possible causes of the problem.

Pressure Gauge (Manifold) Assembly

A ***pressure gauge assembly***, or ***manifold gauge assembly***, typically consists of two pressure gauges, a manifold, two on-off valves, and three service hoses, **Figure 84-4**. The pressure reading on these gauges is affected by the outside temperature.

The low-pressure gauge measures suction, or low-side pressure. In cold weather, the low-side pressure reading may be only 31 psi. In hot weather, the low-side pressure reading for the same A/C system might be 45 psi because greater pressure is needed to sufficiently cool the evaporator. The high-side pressure gauge is used to measure compressor discharge pressure, or high-side pressure. A lower pressure reading of 150 psi may register in cold weather. Higher readings, nearing the 300 psi maximum, might be produced in weather nearing 100°F. See **Figure 84-5**.

The two outer service hoses connect to fittings on the air conditioning system. The center service hose is commonly connected to a recovery or recycling unit for cleaning or evacuating or to a refrigerant container for charging (filling) the system.

Service Valves

Service valves provide a means of connecting the pressure gauge assembly for testing, discharging, evacuating, and charging (filling) the air conditioning system. Most systems have two service valves; a few have three. The service valves may be located on the compressor fittings or in the refrigerant lines.

There are two basic types of service valves: Schrader valves and stem valves. These two types also vary for R-12 and R-134a systems.

A ***Schrader service valve*** is a spring-loaded valve, similar to the air valve in a tire. The service

Copyright Goodheart-Willcox Co., Inc.

Low-side Gauge

High-side Gauge

Goodheart-Willcox Publisher

Figure 84-5. A/C pressure gauges give normal operating high- and low-side pressures for R-134a systems. The low-side gauge should read between 25–45 psi. The high-side gauge should read 150–300 psi.

hoses on the pressure gauge set have depressors that open these valves. This is the most common type of service valve found on late-model vehicles. See **Figure 84-6**.

An R-134a service valve has a quick-disconnect fitting that accepts a corresponding fitting on the R-134a gauge set service hose. Before connecting these fittings, make sure the thumb screw on the hose fitting is turned all the way out. Pull back the sleeve on the hose fitting while pushing the hose fitting onto the service valve fitting. Release the sleeve to lock the fittings together. Finally, tighten down the thumb screw to depress the valve. An R-12 service valve has a threaded male fitting that accepts the female fitting on the R-12 service hose. This is shown in **Figure 84-6**.

Dust caps screw over the Schrader service valves to keep out debris and to prevent accidental opening of the spring-loaded valves. Dust caps should always be reinstalled after A/C system service, **Figure 84-7**.

Caution

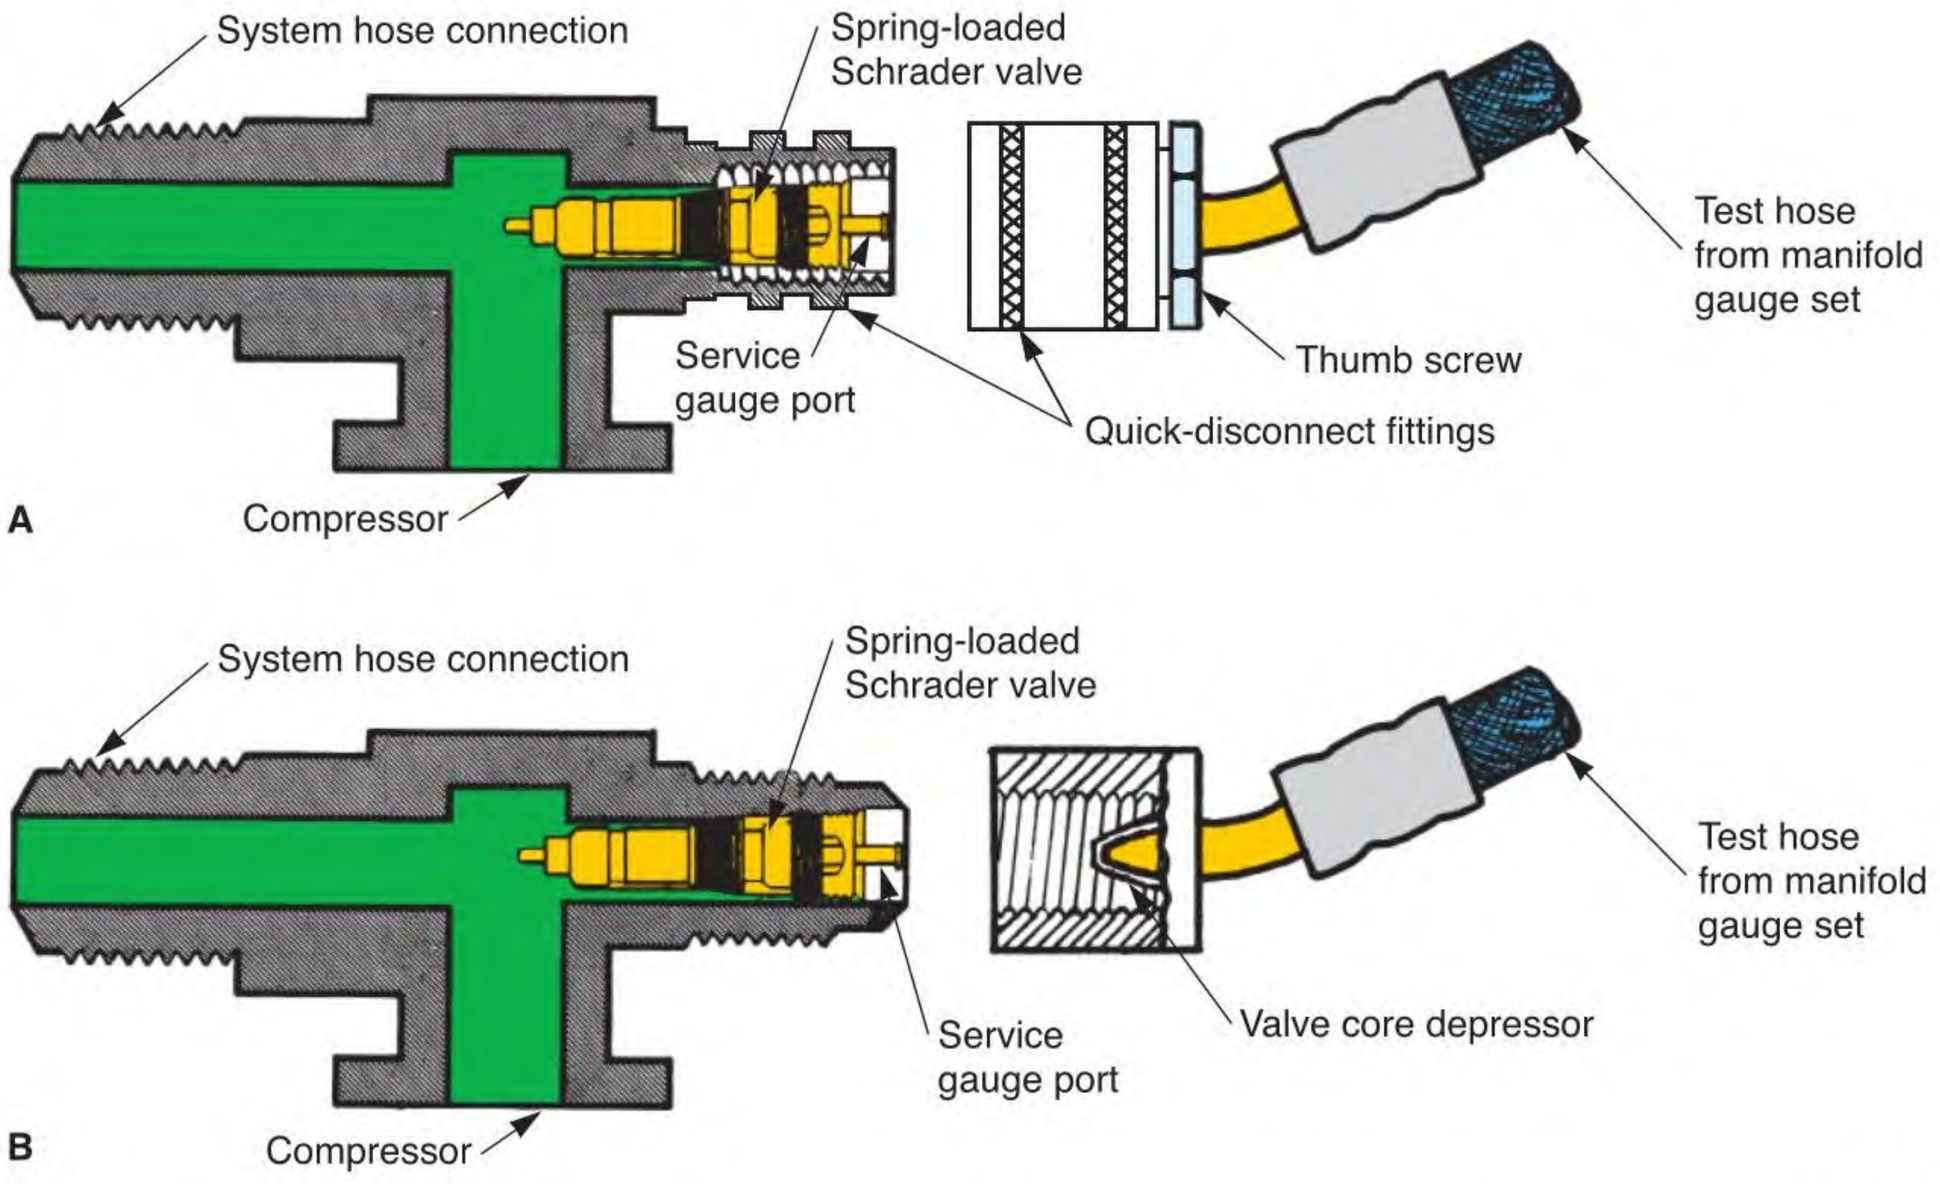
Never operate an air conditioning system when stem-type valves are in the frontseated position. Excessive pressure could build in the compressor, causing part overheating and damage.

Connecting A/C Pressure Gauges

With the engine stopped and safety glasses on, remove the dust caps from the service valves. Make sure the pressure gauge valves are both closed.

Connect the high-side line first. Screw the *red* (high-side) hose fitting on the high-side service valve. Then screw the *blue* (low-side) hose fitting over the low-side service valve, **Figure 84-8**.

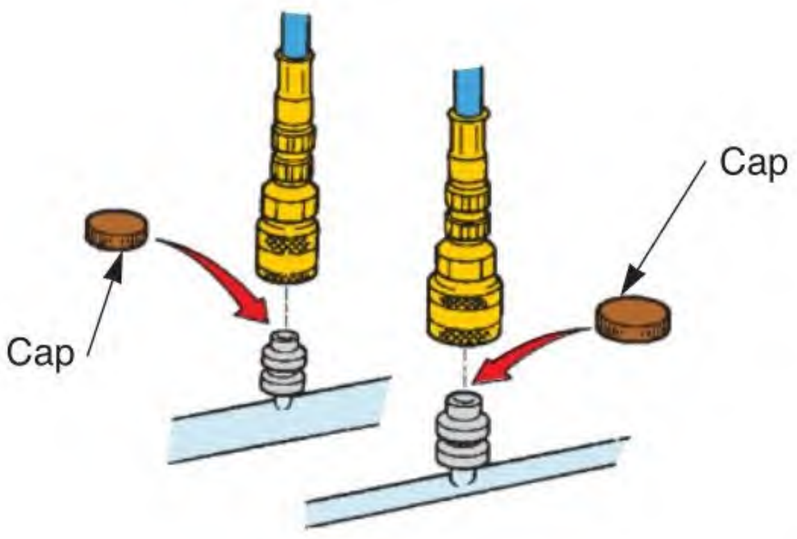
If you have stem-type service valves, turn them 1 1/2 turns clockwise. You can then measure air conditioning system pressures and cooling temperatures as a means of testing the system. This setup will also let you discharge or charge the system.



Static A/C Pressure Reading

A ***static A/C pressure reading*** indicates how much refrigerant is in the system. With the engine *off*, read the high-side pressure gauge. If the high pressure gauge shows approximately 50 psi (345 kPa), the system should have an adequate charge. If the pressure gauge reads below 50 psi (345 kPa), some of the refrigerant charge has leaked out and the system should *not* be operated. Correct any leaks and add refrigerant before making other tests.

Performance Testing A/C System



A ***performance test*** indicates air conditioning system condition by measuring cooling vent temperatures as well as system pressures with the engine running.

Snap-on Tool Corp.

Figure 84-6. A Schrader service valve has a valve core that is similar to one used in a car tire. When the pressure gauge hose is connected to the valve, the valve is pushed open to allow gas flow. A—Quick-disconnect fittings are used in R-134a systems. B—Service fittings for R-12 systems will have male threads.

Mazda

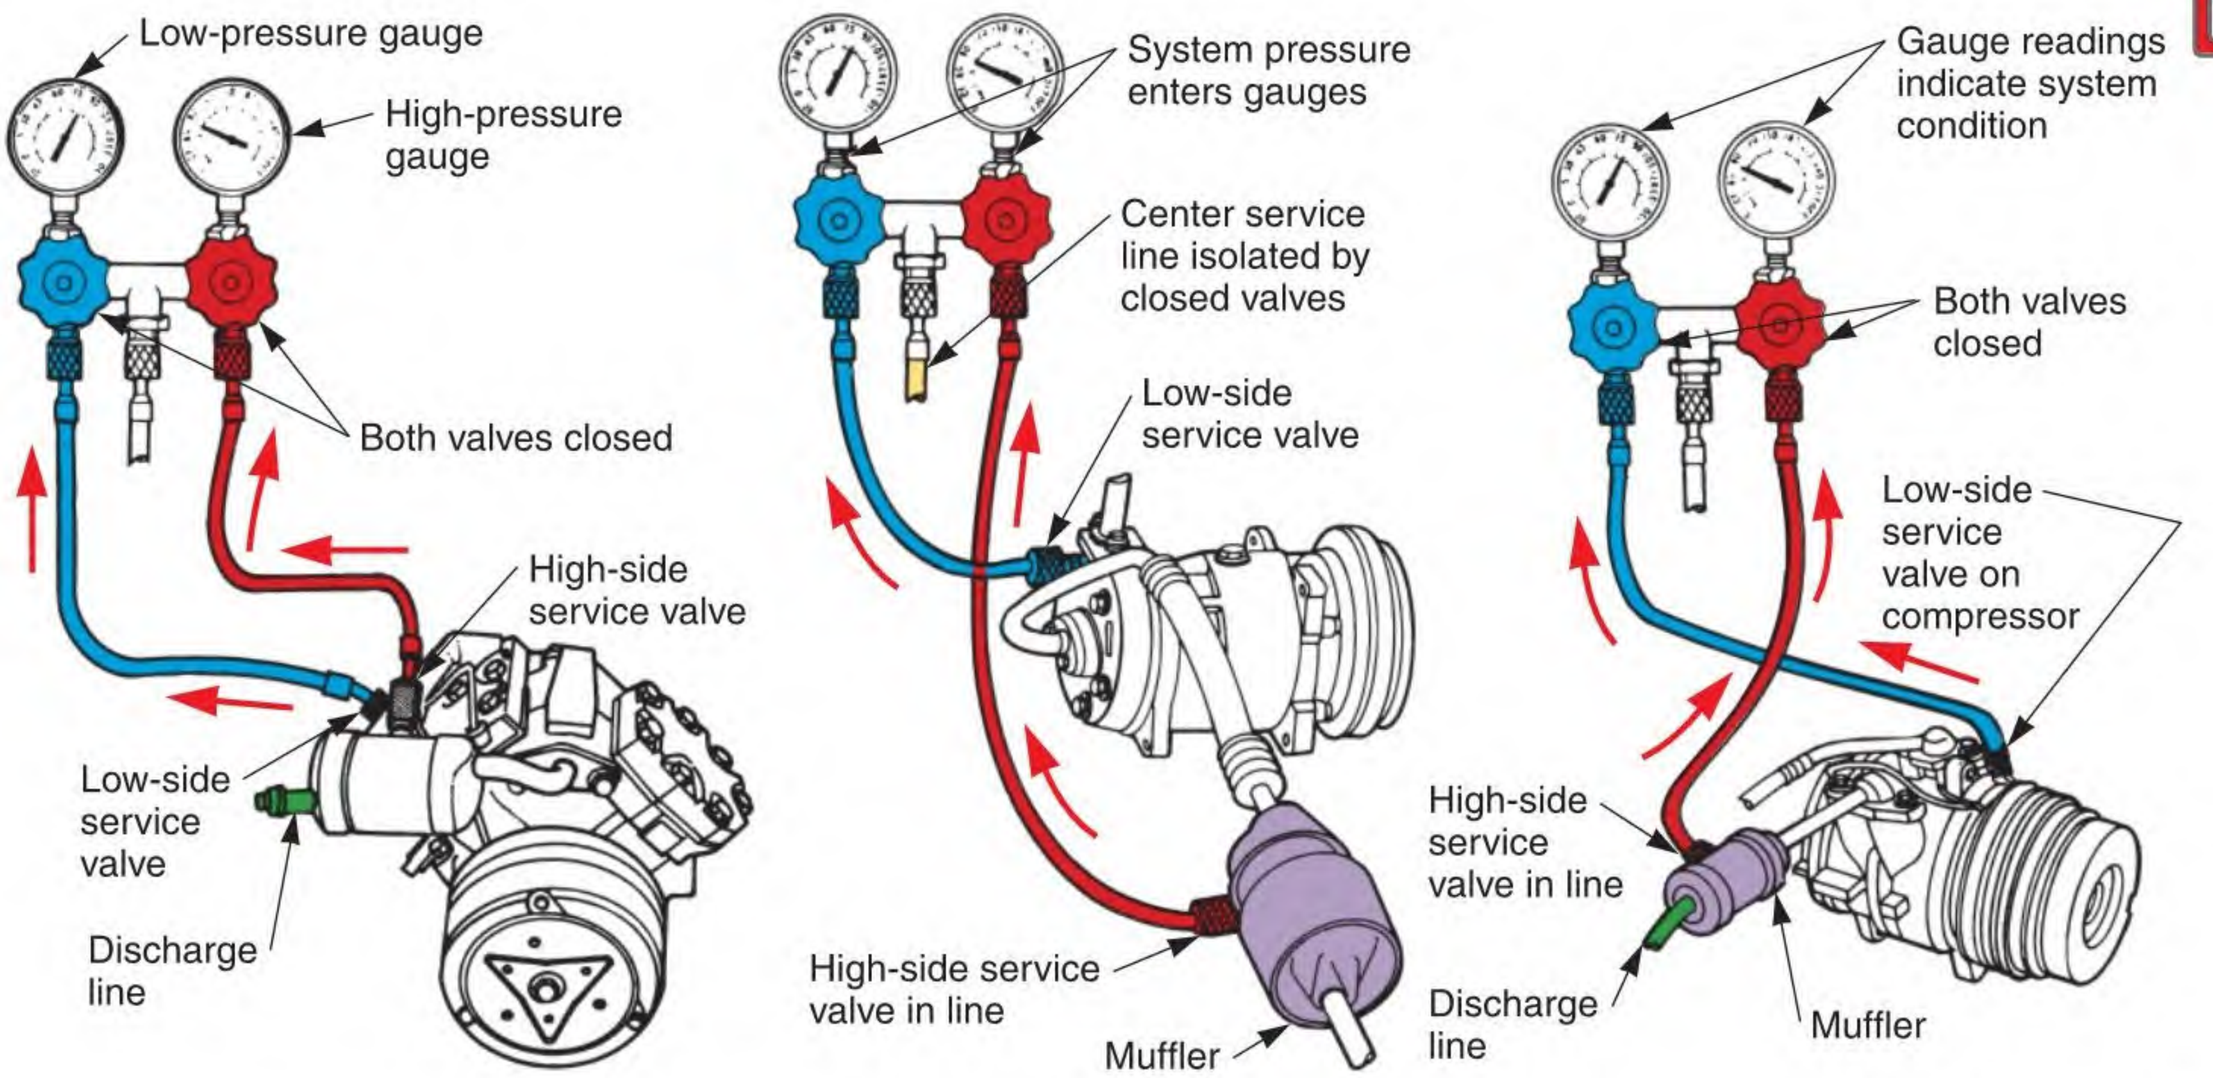

Figure 84-7. Dust caps protect Schrader valves from being filled with dirt and from accidental opening. Always reinstall the plastic caps on the service fittings.

Service Procedure

To conduct an A/C system performance test:

1. Connect an exhaust vent hose over the car's tailpipe.
2. Start the engine.
3. Set the system for maximum cooling and make sure the compressor is spinning.
4. Allow the A/C system to operate for about 10 minutes to allow pressures to stabilize.
5. Place a temperature gauge in a center air outlet in the passenger compartment. Slide the metal shaft on the temperature gauge fully down into the vent, **Figure 84-9**.
6. Close the vehicle's doors and windows. Leave the hood fully open.
7. If it is hot outside (above 85°F or 29°C), aim a large shop fan at the condenser to improve heat removal.

Copyright Goodheart-Willcox Co., Inc.

Florida Dept. of Voc. Ed.

Figure 84-8. Study how a pressure gauge is connected. The manifold valves are kept closed, so that refrigerant cannot flow out the center hose on the manifold.

A B

Goodheart-Willcox Publisher

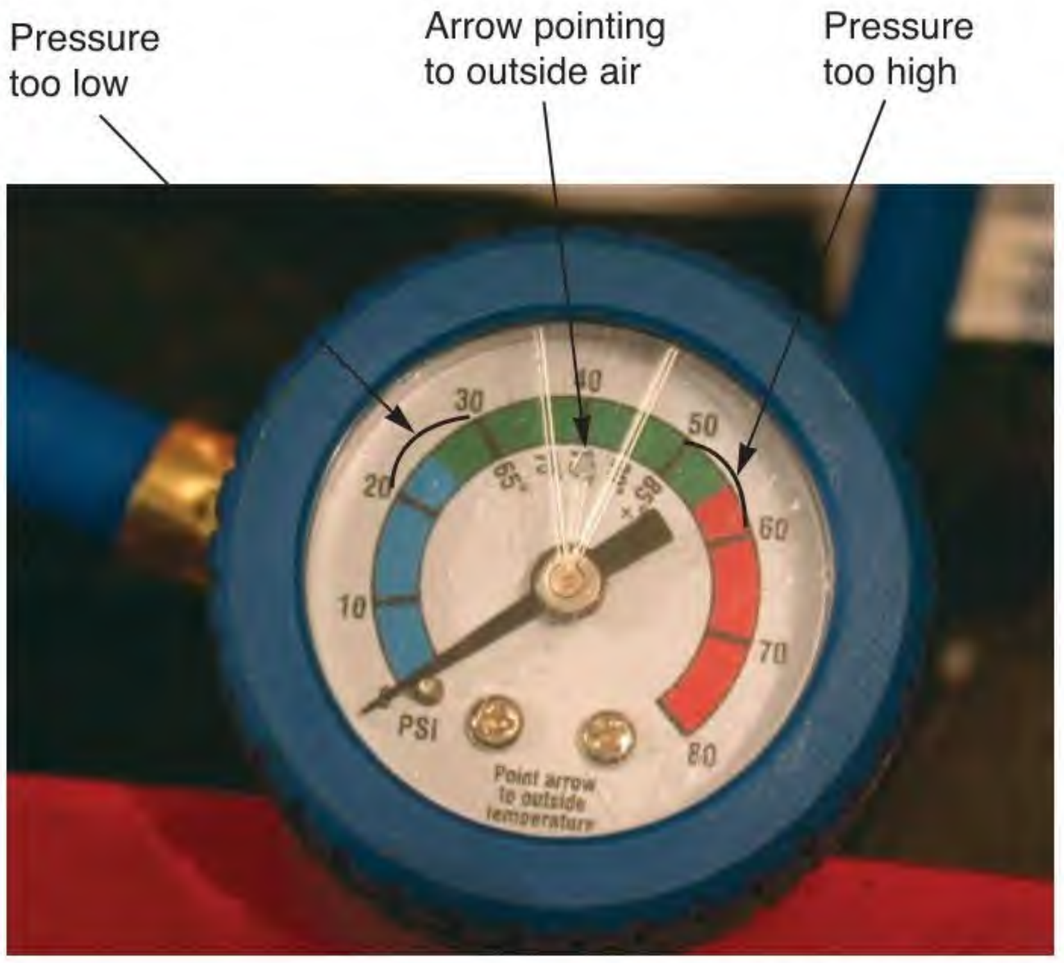

Figure 84-9. Use a temperature gauge to get a reading in a passenger compartment air vent. A—Remove the plastic sleeve to expose the metal shaft. B—Insert the thermometer shaft fully into the center vent in the dash.

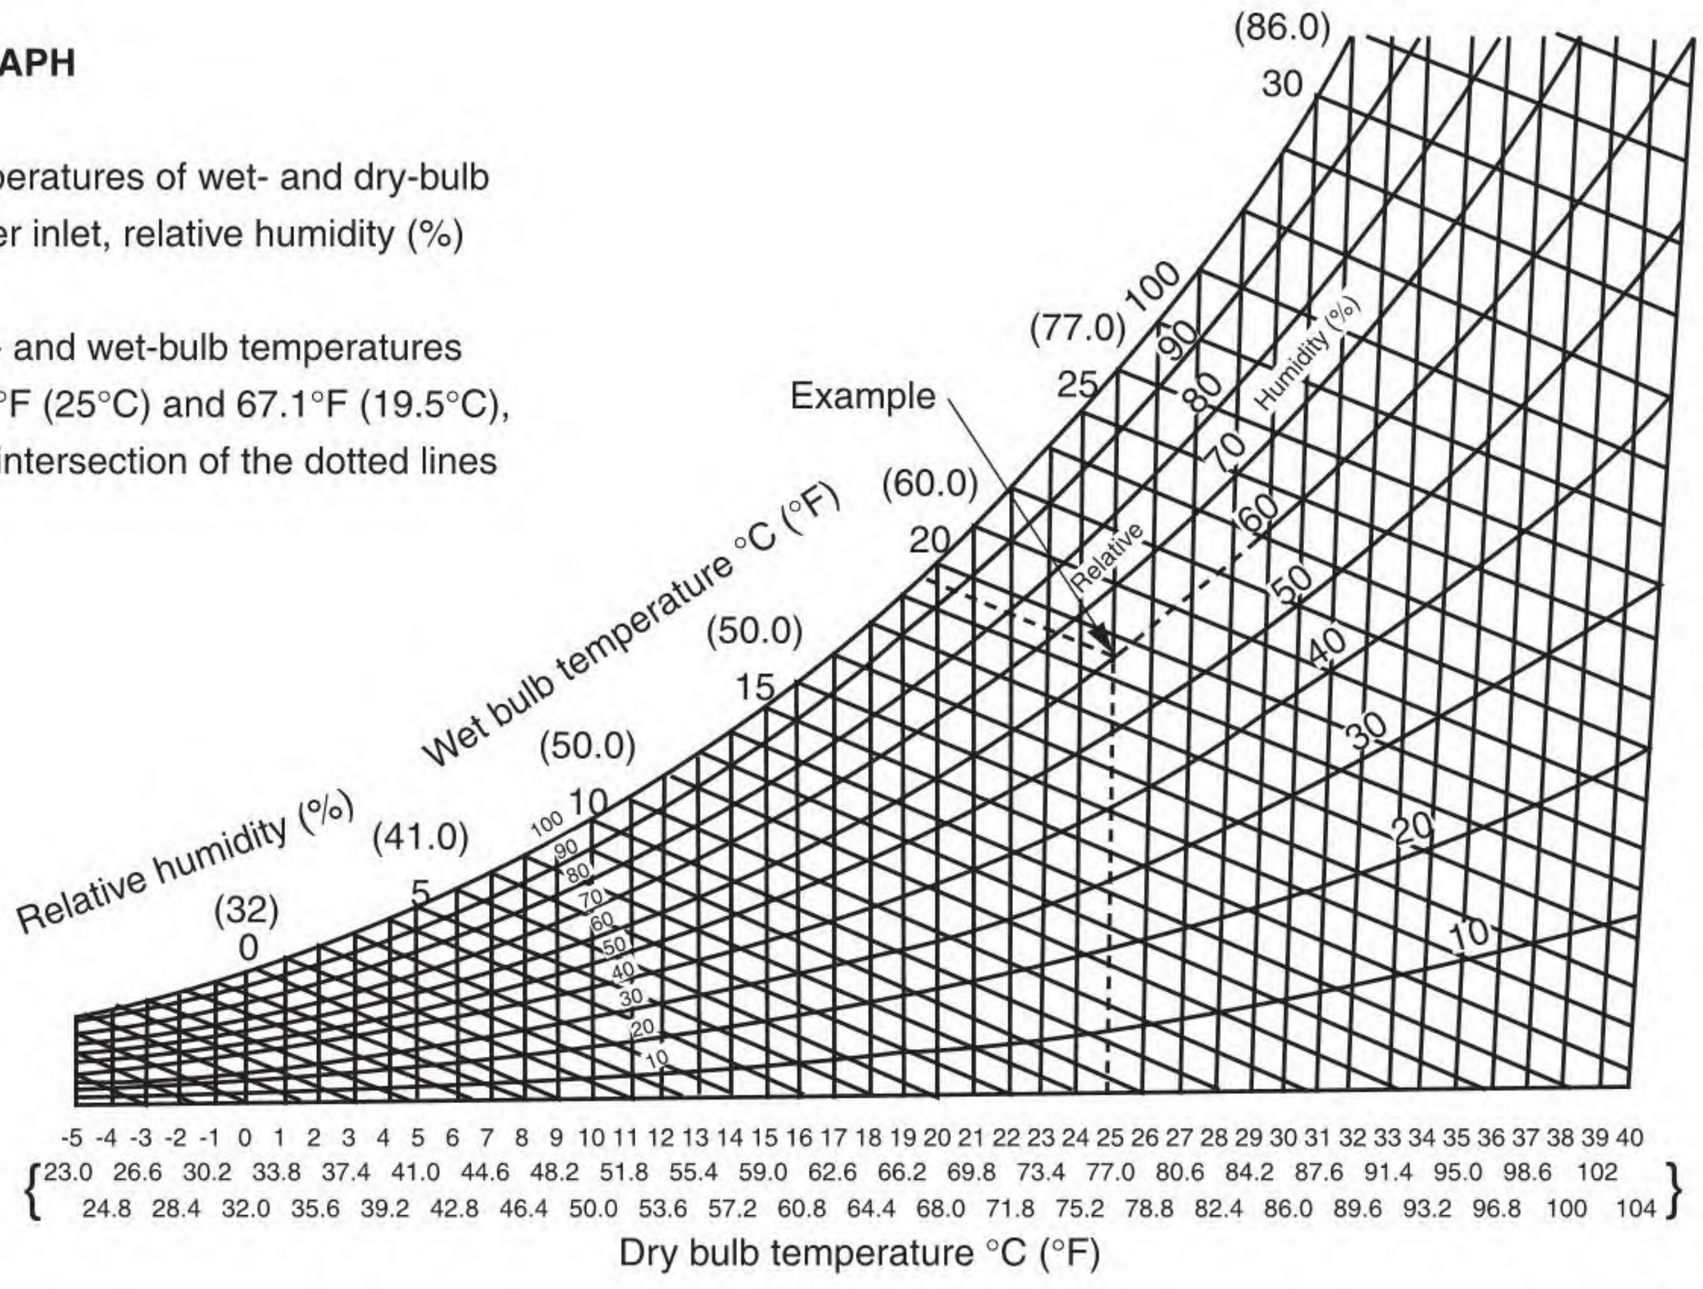
Copyright Goodheart-Willcox Co., Inc.

8. Place another temperature gauge at the condenser to measure ambient (outside) air temperature. See **Figure 84-10**. Both temperatures are usually needed to fully analyze system performance.
9. With R-134a, some manufacturers also require you to measure wet- and dry-bulb temperature at the blower inlet. Use a chart to find the relative humidity, which affects system operation and pressures. See **Figure 84-11**.
10. Compare pressure and temperature readings, as well as relative humidity, to factory specs.

The dash vent temperature reading should be approximately 38–60°F. In hot weather nearing 100°F ambient temperature, air at 57°F blowing out the vents will feel quite cool. In less extreme heat, the center vent temperature should be around 40°F. Note that pressure gauge readings vary with ambient air temperature, humidity, and system design.

If your pressure gauge readings are not within factory specs, there is a problem in the system.



Goodheart-Willcox Publisher

Figure 84-10. Notice the outside temperature arrow on this low-side pressure gauge. Aim the arrow at the outside or ambient temperature of the shop. The reference lines then note the pressure range for a properly functioning A/C system.

HOW TO READ THE GRAPH

After measuring the temperatures of wet- and dry-bulb thermometer at the blower inlet, relative humidity (%) can be obtained.

Example: Supposing dry- and wet-bulb temperatures at the blower inlet are 77°F (25°C) and 67.1°F (19.5°C), respectively, the point of intersection of the dotted lines in the graph is 60%.

Mazda

Figure 84-11. A chart like this will help you convert wet- and dry-bulb thermometer readings into humidity. Note the directions in the upper-left corner.

Copyright Goodheart-Willcox Co., Inc.

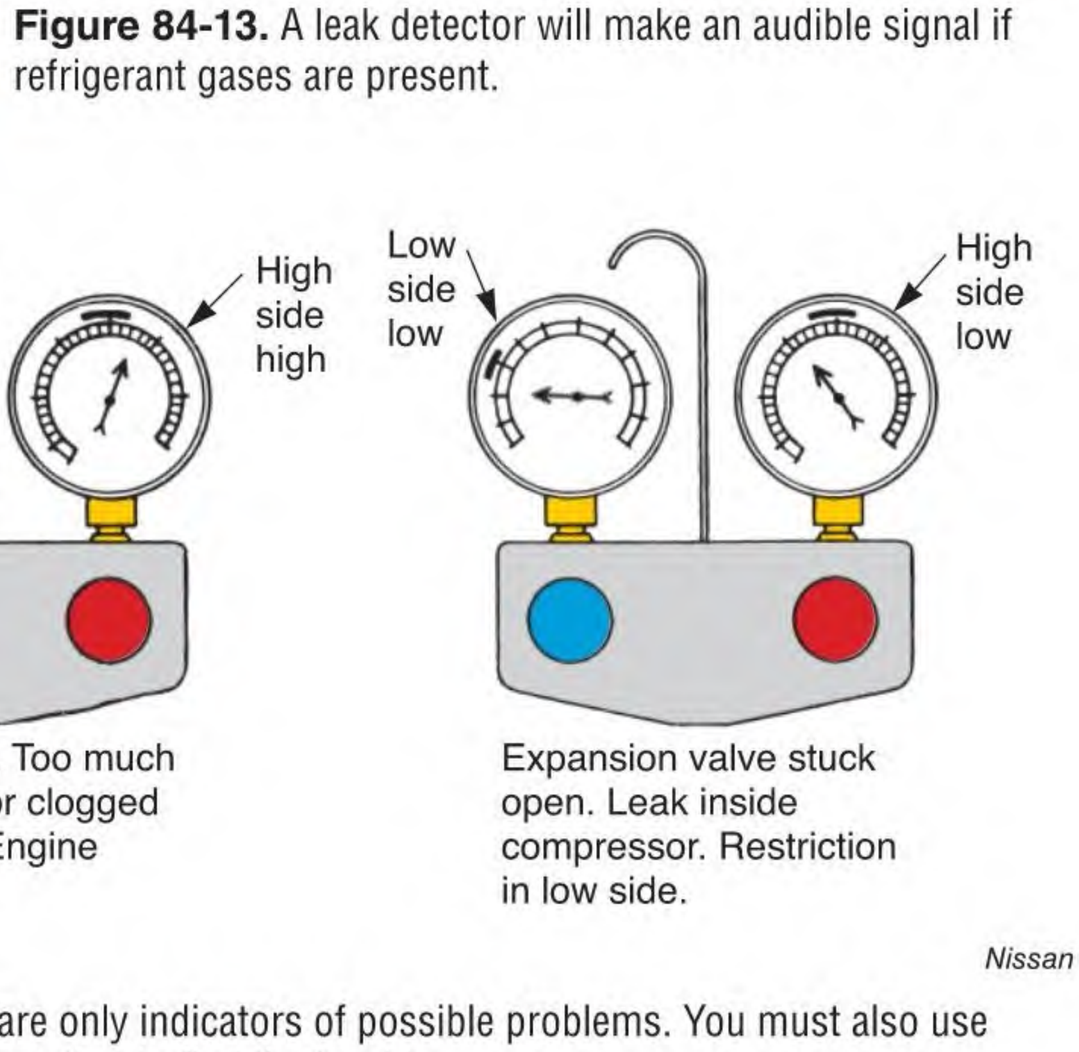
You must use the gauge readings, other symptoms, service manual diagnosis charts, and your knowledge of system operation to pinpoint the problem. A few examples of improper gauge readings are pictured in **Figure 84-12**.

Locating A/C System Leaks

An air conditioning system is considered leaking (needing repairs) when more than one-half pound of refrigerant must be added per year. There are several methods used to locate leaks.

An ***internally charged detector*** is a colored agent that can be charged into the system. Any leak shows up as a bright color spot (usually orange-red) at the point of leakage.

A ***bubble detector*** is a solution applied on the outside of possible leak points. The leaking refrigerant will make bubbles or foam in the leak-detecting solution.



A ***torch detector*** uses a gas flame to indicate A/C leaks. Leaking refrigerant is drawn into and changes the color of the flame. If the flame does not change color, refrigerant is not present. This type of detector has been phased out for the safer electronic leak detector.

Warning

When some refrigerants are burned, a very toxic phosgene gas is produced. If it is necessary to use a torch detector, use only in a ventilated area. Keep your face away from the detector to avoid inhaling fumes.

An ***electronic leak detector*** uses a special sensor and an electronic amplifier to locate A/C leaks. It produces a sound or light signal when refrigerant is detected. See **Figure 84-13**.

An electronic leak detector is the fastest, safest method of locating system leaks. To use an electronic leak detector, move the tester's probe around possible leakage points, such as service ports, line fittings and connections, condenser, compressor seals, valves, and evaporator. Check under the fittings and seals

Snap-on Tool Corp.

Figure 84-13. A leak detector will make an audible signal if refrigerant gases are present.

Nissan

Figure 84-12. Basic gauge readings, whether too high or too low, are only indicators of possible problems. You must also use information on system design and your knowledge of A/C system operation to find the trouble.

Copyright Goodheart-Willcox Co., Inc.

since cold gas tends to settle downward in a warm shop. When the tester buzzes or lights up, you have found the leaking component.

Tech Tip

Loose refrigerant line fittings are one of the most common sources of A/C system leaks. Tighten leaking fittings and retest them for leaks, **Figure 84-14**. If tightening does not correct the leak, replace the hose or line if needed.

Recovering Refrigerant

Technicians must use a ***refrigerant recovery machine*** to capture, store, filter, and recycle all used R-134a gas from repaired vehicles. See **Figure 84-15**. According to federal law, it is illegal to allow used refrigerant gas to escape into the shop area during repairs. The refrigerant gas that is drawn out of the vehicle's A/C system must be stored and recycled.

The recovery machine automatically filters the used R-134a and prepares the gas to be reused in another vehicle, **Figure 84-16**. Oil is separated from the refrigerant gas before circulating the gas through filter-driers to remove acids, moisture, and other contaminants. After filtering out water and other impurities, the clean R-134a gas can be charged into an empty vehicle A/C system.

Tech Tip

An automotive technician from St. Louis, Missouri, was the first person convicted of a crime for releasing automotive refrigerant into the atmosphere. The technician admitted to the offense and was prosecuted under a federal law written to protect the earth's atmosphere from further damage.

Never allow automotive refrigerant to escape into the atmosphere. Although you may not get caught, releasing refrigerant into the atmosphere contributes to our environmental problems. If everyone ignored this law, future generations could suffer serious consequences from ozone layer depletion and global warming

Snap-on Tool Corp.

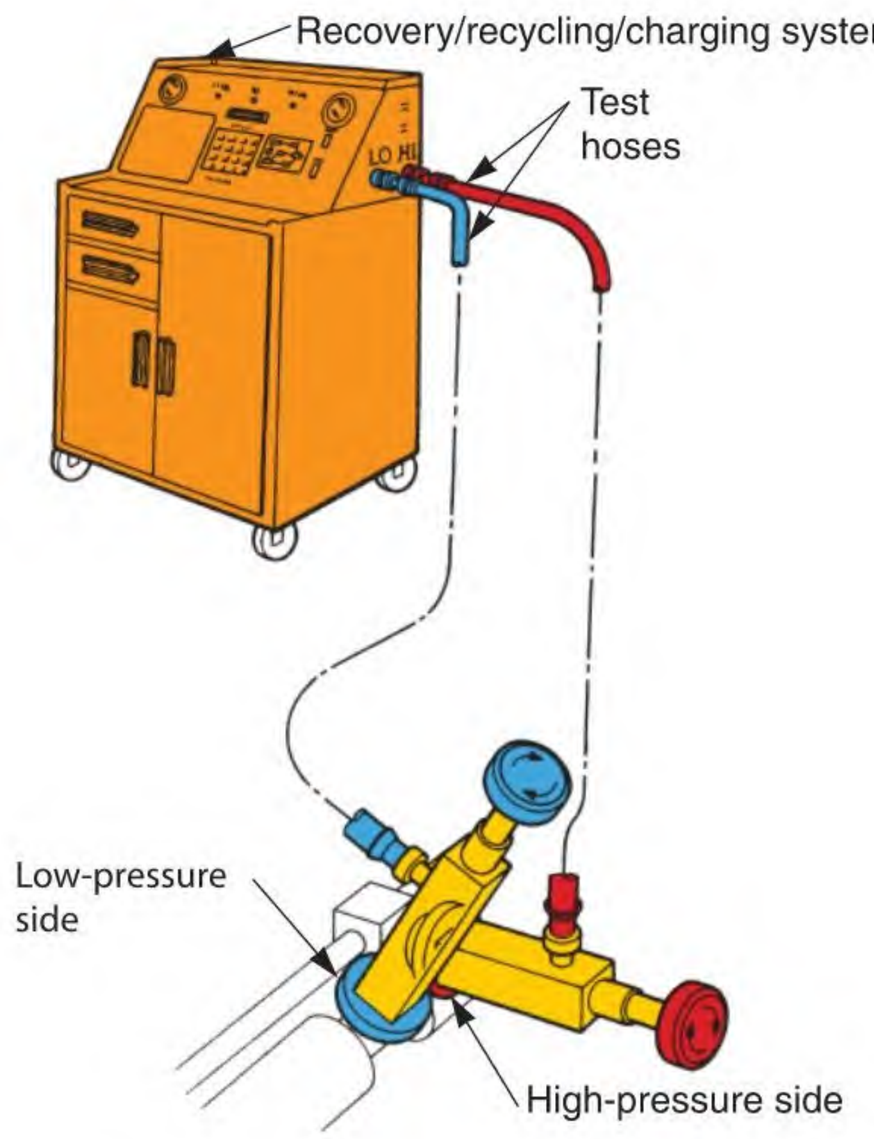


Figure 84-14. If a fitting is leaking, try tightening it. Use two wrenches or one wrench and a torque wrench, if possible.

Snap-on Tool Corp.

Figure 84-15. This typical charging station includes a recovery unit to withdraw refrigerant from an air conditioning system. The refrigerant is stored in a refillable container for reuse or recycling.

Copyright Goodheart-Willcox Co., Inc.

Snap-on Tool Corp.

Figure 84-16. The charging station connects to the vehicle like a pressure gauge set. A vacuum pump evacuates the system and a refillable container holds old, captured refrigerant.

R-12 and other older refrigerants can be recycled, as well. Recycling has become increasingly important as the reserve of R-12 and other CFC refrigerants is depleted. Environmentally safer refrigerants (such as R-134a) are used in new vehicles, but the A/C systems in many older cars and trucks still require R-12.

If your A/C recovery machine is not set up for R-12, connect an empty pressure tank to the vehicle's A/C system using your pressure gauge set. Open the gauge valves and the valve on the vacuum tank. Tank suction or vacuum will pull most of the old refrigerant into the tank. Start the engine and the compressor will pump almost all of the remaining R-12 gas and oil out of the vehicle for recycling. To prevent compressor damage, do not let the engine run very long without refrigerant and oil in the A/C system.

Tech Tip

Retrofit kits are available for converting A/C systems designed for R-12 to operate with R-134a refrigerant. The cost of these kits and the amount of labor involved in completing the retrofit varies. Check with the vehicle manufacturer and your parts supplier.

Common A/C Component Problems

When your performance (pressure) tests indicate faulty components, remove and replace or repair the defective parts. This section outlines typical symptoms, problems, and service procedures for common air conditioning components. Refer to a service manual for special procedures and tools.

Tech Tip

Some air conditioning systems use spring-loaded connectors at the ends of refrigerant lines. A special plastic disconnect tool is required to properly disengage these high-pressure line connectors without damaging the fitting, **Figure 84-17**. The connector tool must be the right diameter and design to disengage a spring-loaded, R-134a high-pressure line.

Evaporator Problems

With a bad evaporator, the trouble normally shows up as inadequate cooling. An evaporator can develop leaks that show up when testing with a leak detector around the evaporator case.

If leaking, the evaporator must be removed for replacement. Sometimes, the evaporator is removed from under the dash or it may come out on the engine compartment side of the firewall. Refer to a service manual for details.

A clogged ***evaporator drain*** often causes water to leak onto the carpet in the vehicle under the evaporator housing. The evaporator drain normally allows water to flow from the evaporator housing out of the vehicle, to the ground under the vehicle. The evaporator drain or hose can become clogged with debris. When this occurs, water may slosh around in the housing and may leak onto the floor of the passenger compartment. Additionally, the air conditioning system may produce a musty odor, as mold spores grow in the trapped water.

To clear a clogged evaporator housing drain hose, insert a long piece of mechanic's wire into the end of the housing drain hose to clean out any debris. Water will begin to flow and drip from the hose when the drain is clean. Some manufacturers recommend using compressed air to clear the drain. When using compressed air, be careful not to blow the hose out of the housing.

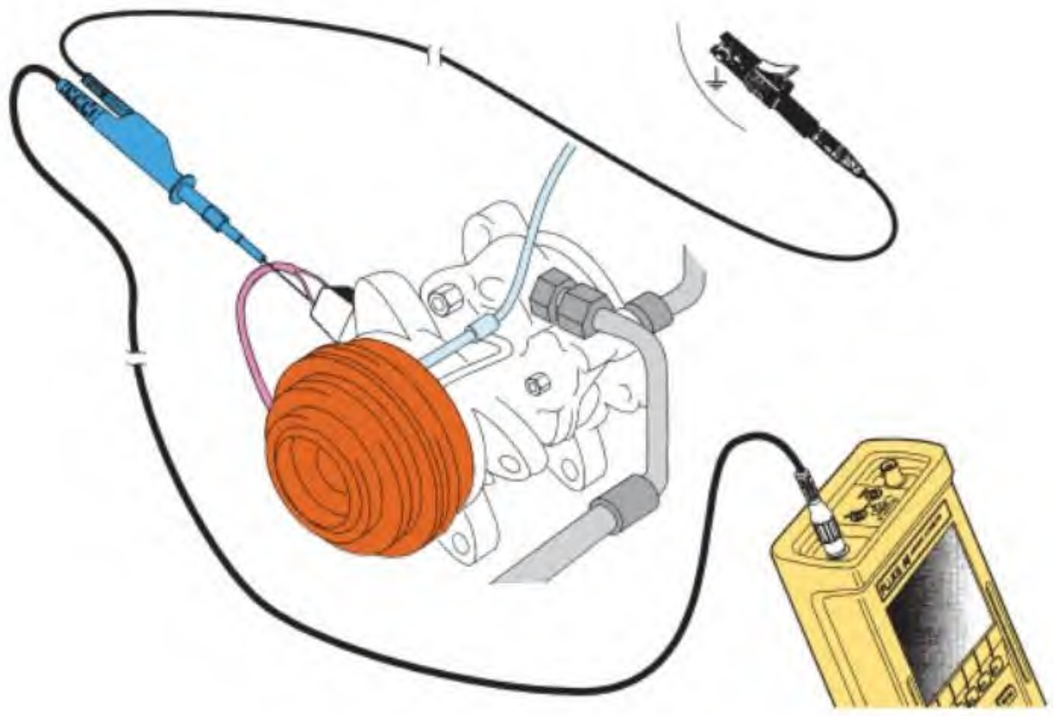
A

B

Goodheart-Willcox Publisher

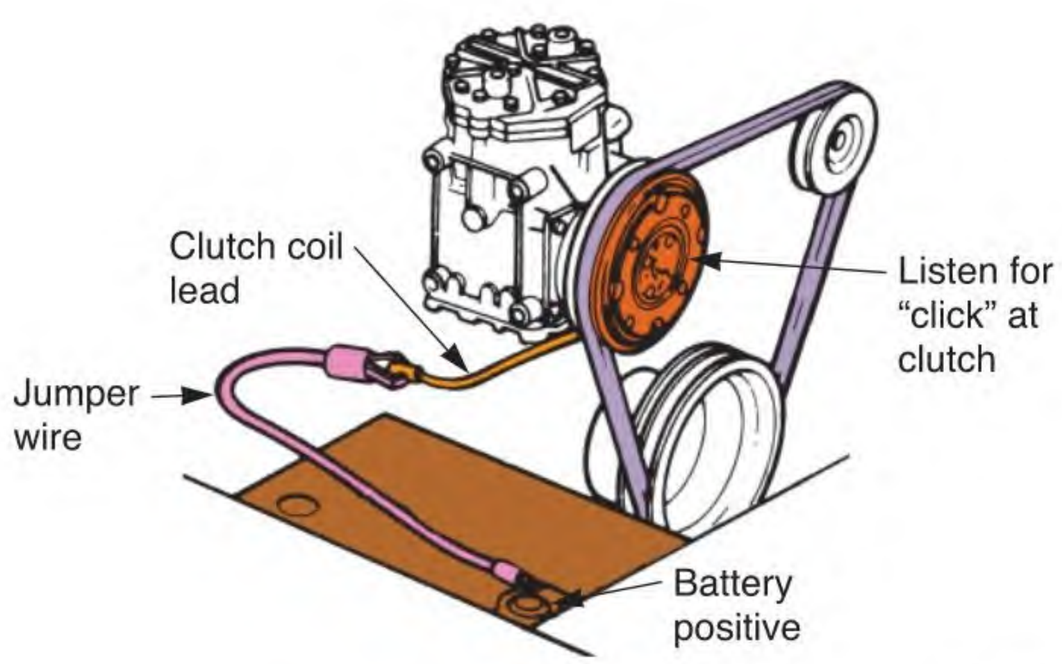
Figure 84-17. To disconnect spring-loaded connectors on the ends of refrigerant lines requires a special tool. A—A/C line tools must be the right size for the spring-loaded fitting. These tools are color-coded by size. B—After removing the clip that surrounds the spring-loaded fitting, seat the tool around the fitting and squeeze while pulling to disconnect refrigerant line.



Compressor Problems

Compressor problems appear as abnormal noises, seizure, leakage, or high inlet or low discharge pressures. Some pumping noise is normal. However, if a loud rattling or knocking noise comes from the compressor, faulty parts may be indicated.

A bad ***compressor shaft seal*** is a common wear problem that allows refrigerant to leak past the compressor shaft and compressor end housing. Always check the compressor seal closely during your leak tests. The seal can sometimes be replaced without compressor removal.



To check the ***compressor clutch***, check for voltage being applied to the clutch magnet. If you are not getting voltage to the clutch wire, find the open in the circuit, **Figure 84-18**. There may be a blown fuse or disconnected wire.

You can also connect battery voltage directly to the clutch. This should produce a clicking sound. If you start and idle the engine, the compressor plate and pulley should lock together to spin the compressor shaft and pump refrigerant through the system. See **Figure 84-19**. This tells you that there is a voltage feed problem to the compressor.

Fluke

Figure 84-18. A multimeter can be used to check for current and voltage to the compressor clutch. If no voltage is reaching the magnetic clutch, check the wiring and the controller.

Chrysler

Figure 84-19. If the compressor fails to turn on, check the clutch by applying battery voltage to the clutch coil. This should make the clutch kick in.

Copyright Goodheart-Willcox Co., Inc.

If the clutch does not engage, the compressor coil may be open or shorted and need replacement. If the clutch engages when connected to battery voltage, there may be a problem in the circuit supplying voltage to the compressor clutch. Trace the circuit and locate the problem (bad switch, wire connection, broken wire, burned relay points, etc.).

Follow the instructions provided in the service manual during compressor service. The manual outlines procedures for compressor removal, disassembly, overhaul, and reassembly. Special tools and procedures are required.

Tech Tip

Air conditioning compressors are complicated to the inexperienced technician. Never attempt to overhaul a compressor without proper training and supervision. Most technicians replace bad compressors with new or rebuilt units.

Condenser Problems

A bad condenser can leak refrigerant or become restricted internally. A restricted condenser causes a high pressure reading in the discharge (high) side of the system. A partial condenser restriction can cause ice or frost to form on the outside of the condenser. During normal condenser operation, the outlet tube is slightly cooler than the inlet tube.

The condenser is fairly simple to replace, as it often mounts in front of the radiator. Its fittings must be loosened and removed. Use tubing wrenches to prevent fitting nut damage. Screws or small bolts often hold the condenser to the vehicle's radiator core (metal framework across the front of the body). During installation, make sure you start the fitting nuts by hand to prevent crossthreading. Be careful not to hit and bend the soft aluminum fins on the new condenser. Bent fins will reduce heat transfer and cooling efficiency in hot weather.

Receiver-Drier Problems

Receiver-drier problems are very common. The receiver-drier is one of the most frequently replaced air conditioning components. The desiccant (drying agent) can become contaminated or the unit may become internally restricted. A restricted receiver-drier alters system pressures, causing the outlet fitting on the unit to become abnormally cold.

A receiver-drier is typically replaced when:

- The sight glass is cloudy.
- System fittings have been left open for more than an hour.
- The system has been leaking and been operated on a partial charge.
- The system has been opened and serviced for the third time.
- Moisture is found in the system.
- A restriction is indicated in the unit.

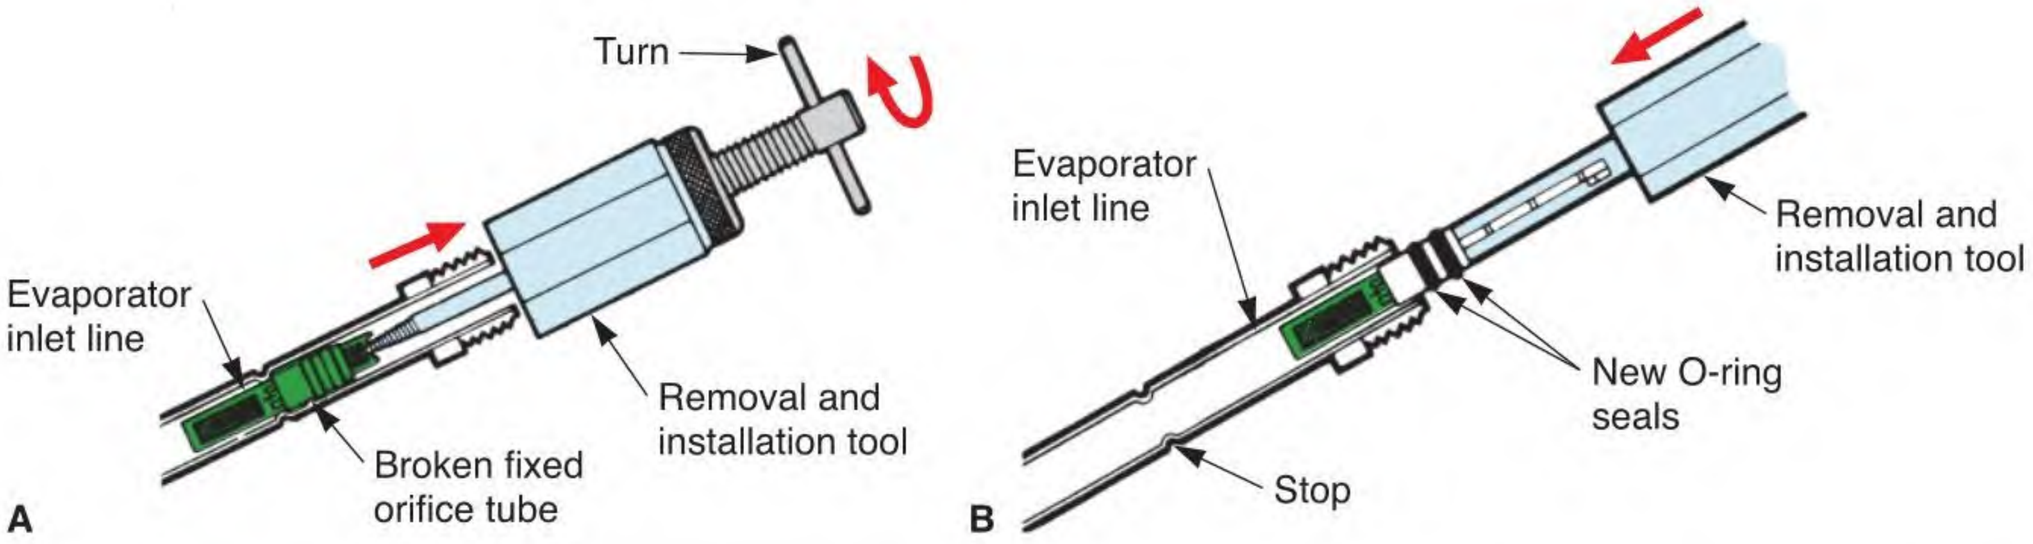
Expansion Valve or Tube Problems

A faulty expansion valve usually shows up as low pressure readings on either the low side (suction) or the high side (discharge) of the system. The failure is often due to the power element (bulb) not operating the valve properly. A less common failure of the expansion valve is due to a clogged inlet screen (corrosion particles, loose desiccant beads, etc.).

A restriction in the expansion valve increases high-side pressure and decreases low-side pressure. A valve that is stuck open decreases pressure on the high-side and increases pressure on the low-side.

A clogged orifice tube will produce symptoms similar to those caused by a restricted expansion valve. Contaminants can fill and clog the orifice tube or the tube screen, blocking refrigerant flow through the system.

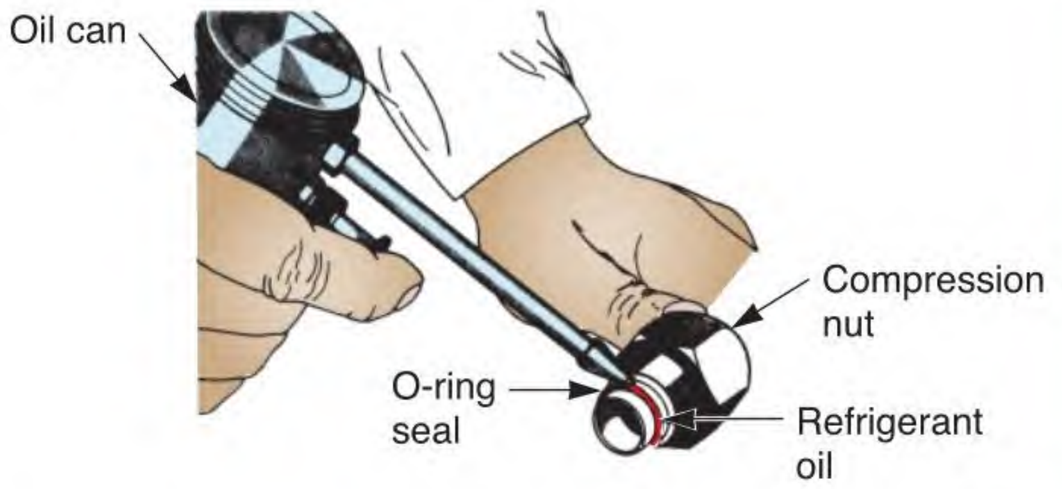
Refer to a service manual for detailed procedures for diagnosing and replacing these and other flow control valves. **Figure 84-20** shows the special tool needed to replace one type of orifice (expansion) tube.



Thermostat Problems

A bad thermostat will usually keep the compressor clutch from engaging. This prevents the system from cooling. If the compressor clutch will not engage during normal system operation but engages when connected to battery voltage, test the thermostat. It may not be sending current to the clutch coil when needed.

Refrigerant Line Problems



Defective refrigerant lines may leak, harden, crack, and restrict refrigerant flow. Replace any refrigerant lines that are faulty. When installing a line using an O-ring seal, coat the seal with refrigerant oil. This will help prevent the seal from leaking, **Figure 84-21**.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

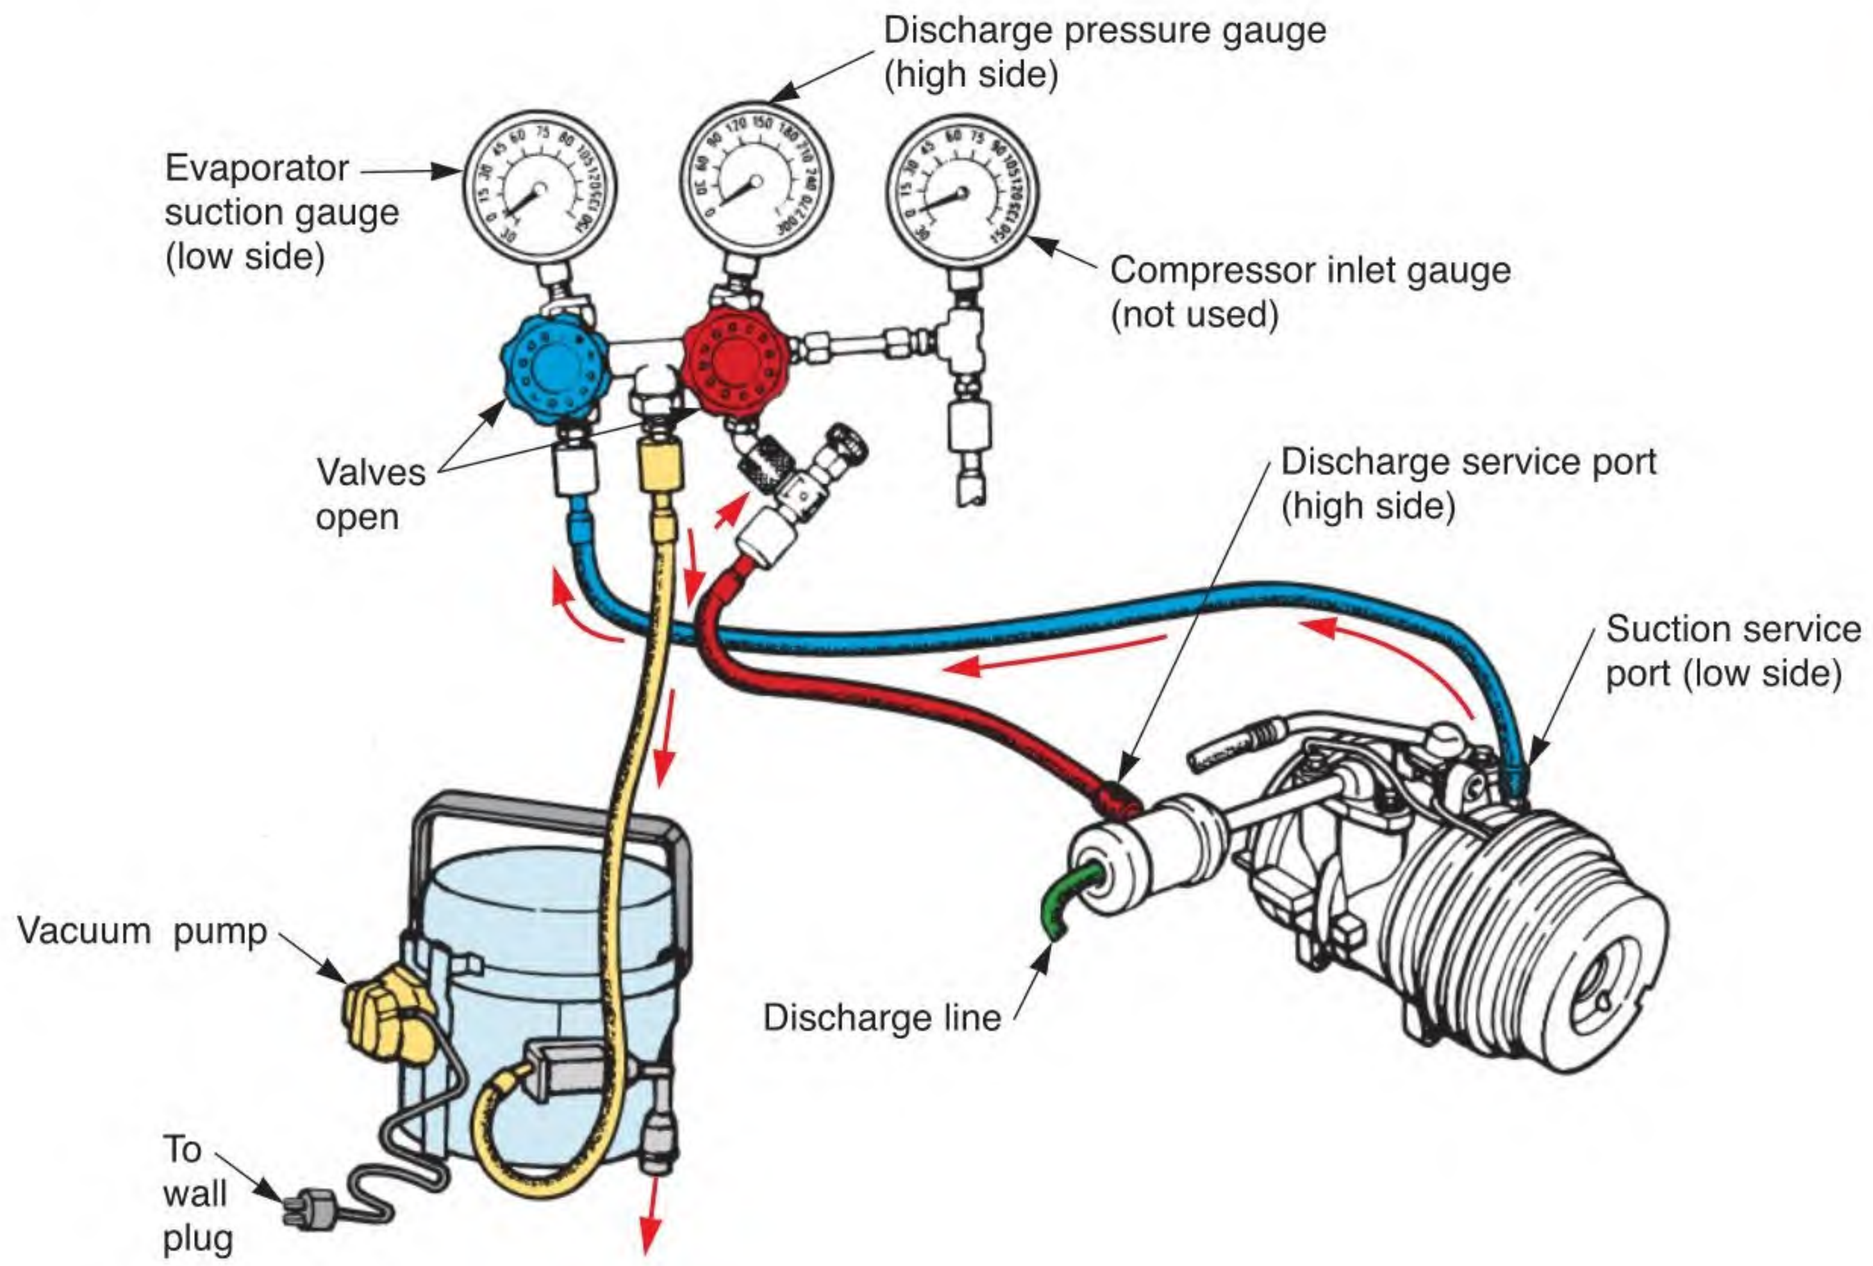
Figure 84-21. Lubricate all A/C system O-rings and seals with refrigerant oil. This will help seal them and prevent leaks.

Evacuating an Air Conditioning System

A/C system evacuation involves using a vacuum pump to remove air and moisture from the inside of the vehicle's refrigerant system, **Figure 84-22**. Evacuation is needed anytime the air conditioning system has been discharged or opened to the atmosphere.

Service Procedure

To evacuate an A/C system:



1. Connect the pressure gauges to the system.
2. Connect the vacuum pump to the center service hose on the gauge set.
3. If necessary, open the compressor valves (stem type).
4. Open the valves on the pressure gauge set.
5. Plug in and turn on the vacuum pump.
6. Operate the vacuum pump until the pressure gauges read approximately 26–28 inches of mercury (in. Hg) at sea level.
7. After reaching the necessary pressure reading, run the pump another 5 or 10 minutes to ensure complete removal of air and moisture.
8. If you cannot draw the amount of vacuum recommended by the service manual, check the operation of the pump and examine the system for leaks. This is an easy way to detect major leaks before installing refrigerant.
9. After evacuating the system, shut off the vacuum pump and close both gauge valves.

   The system vacuum should not drop more than 2–3 in. Hg in a five-minute period. If it does, a small system leak is indicated. You must leak-test the system as described earlier.

Charging an Air Conditioning System

A/C system charging involves filling the system with the correct amount and type of refrigerant. See **Figure 84-23**. The system should be charged only after it has been leak-tested and evacuated. Most shops use 10- to 30-pound containers of refrigerant. However, larger bulk containers are also used.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 84-22. Connect the vacuum pump as shown to evacuate the system.

Goodheart-Willcox Publisher

Figure 84-23. This 12-ounce can of refrigerant is often called a "pound can of refrigerant," even though it is not 16 ounces.

Service Procedure

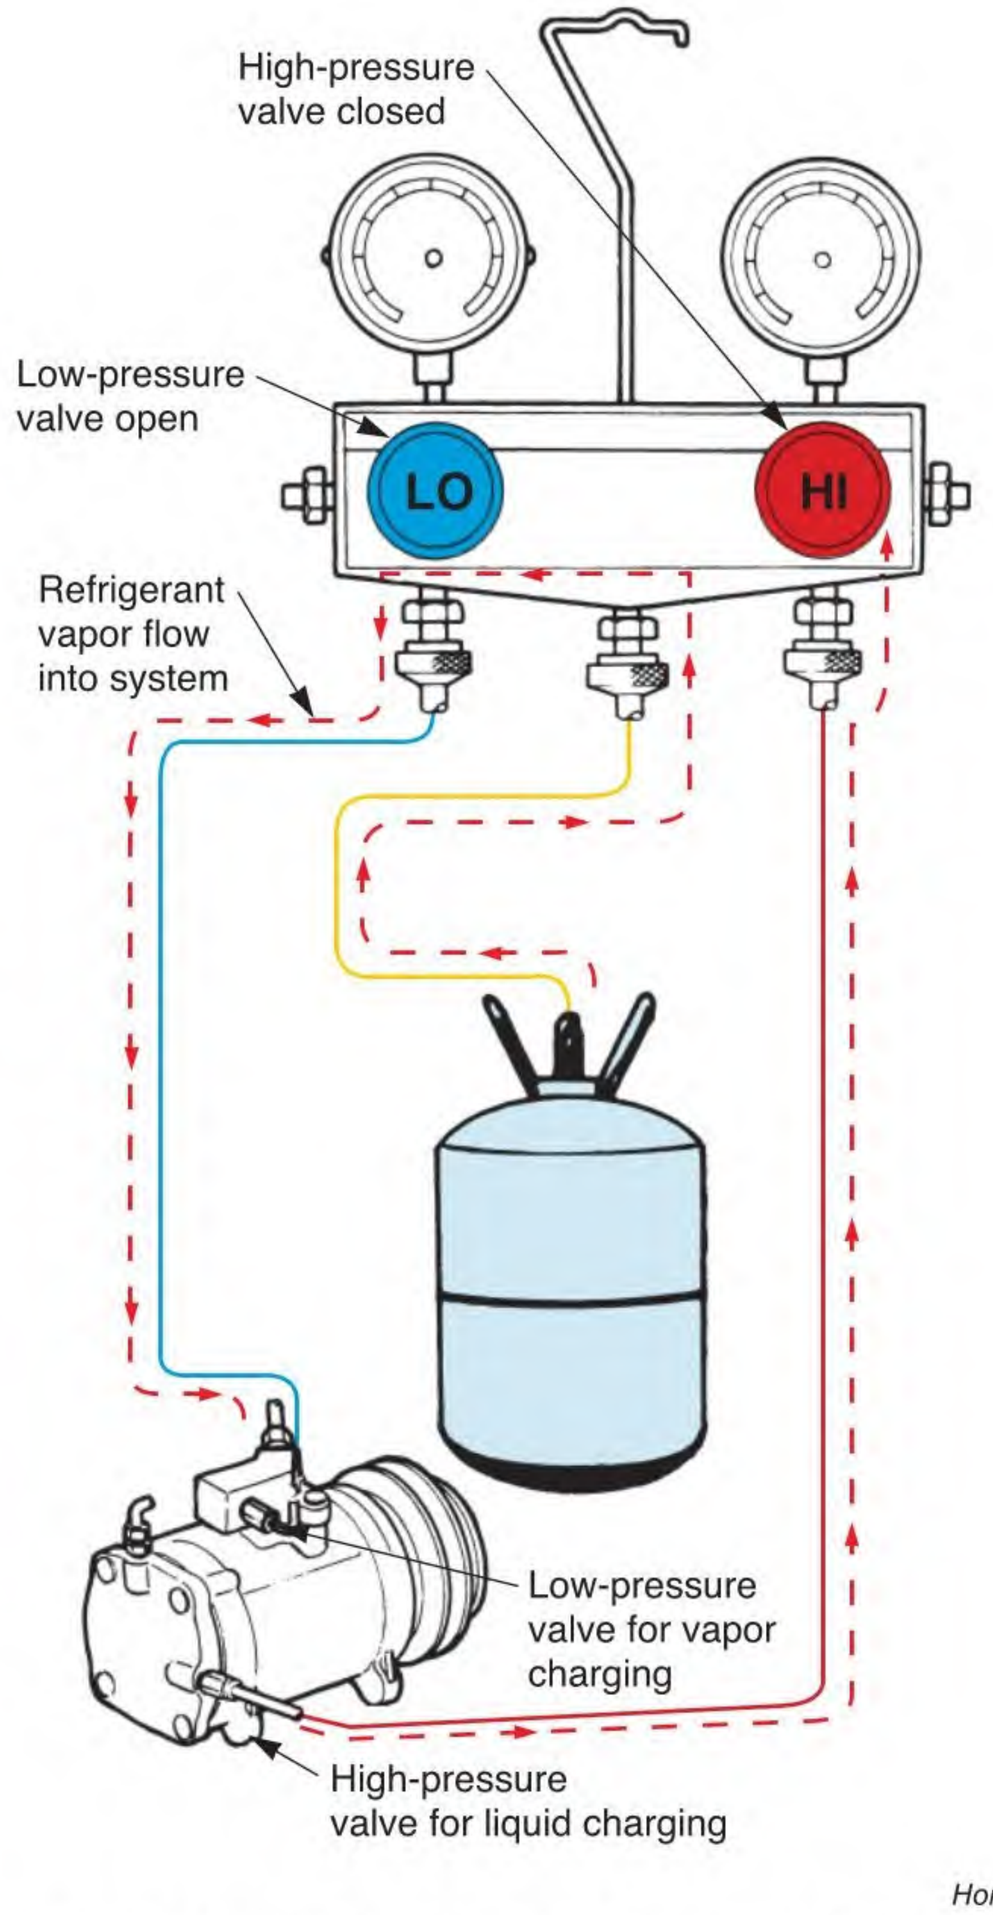
To charge an A/C system:

1. Leave the pressure gauge set attached to the A/C system after evacuation.
2. Remove the center hose from the vacuum pump and connect it to the refrigerant container or charging station.
3. With the gauge valves closed, connect the center hose to the refrigerant container, **Figure 84-24**.
4. Open the center valve of the manifold gauge set and the service valve on the refrigerant container. This will transfer control of refrigerant flow to the gauge valves.
5. To charge the system, open the gauge suction (low-pressure) valve but leave the gauge discharge (high-pressure) valve closed. See **Figure 84-25**.
6. Start the engine and adjust the A/C system to maximum cooling. Compressor suction will then draw refrigerant into the system.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 84-24. A special spike fitting on the dispenser hose must puncture the sealed top on a pound can of refrigerant.



7. Adjust the gauge suction valve so that gauge pressure does *not* exceed 50 psi (345 kPa). This will ensure that liquid refrigerant does not enter and damage the compressor.

Tech Tip

You may want to place the refrigerant container in warm water—not hotter than 125°F (52°C). This will expand the refrigerant, helping it to flow into the system.

Keep the refrigerant container right-side up when charging. This will ensure that only refrigerant vapor, not liquid refrigerant, enters the system.

After charging the A/C system, double-check system pressures and temperatures. Make sure the high- and low-side pressures are satisfactory. Also, use a thermometer to measure the temperature of the air blowing from the passenger compartment vents. If these checks are within specs, the air conditioning system is ready to be returned to service.

Honda

Figure 84-25. Attach the refrigerant container to the center hose. Open the lower pressure valve and allow refrigerant to flow into the low side of the system with the engine running.

Charging Station

A ***charging station*** usually contains a vacuum pump, a pressure gauge set, an oil injection cylinder, and a charging tank of refrigerant. A charging station can be used to evacuate and charge the system without disconnecting the service hose. The general procedures for using a separate vacuum pump, refrigerant container, and test gauge set should be followed when using a charging station. Remember to follow the directions for the specific type of equipment.

Copyright Goodheart-Willcox Co., Inc.

Adding Refrigerant Oil

The refrigerant oil level should be checked anytime you add or replace refrigerant. Before checking the refrigerant oil, operate the system for 10–15 minutes. Then, isolate the compressor by closing the stem-type service valves. If Schrader valves are used, you must discharge the system to check the oil level.

Refer to a service manual for detailed procedures for checking the refrigerant oil level. Follow instructions for the type of compressor you are servicing.

If the oil is low, add the specified amount and type of refrigerant oil. Do not overfill the compressor, or system efficiency will be reduced. If the refrigerant oil is dirty, the system should be evacuated, flushed, and refilled.

Tech Tip

Make sure you use the right type of compressor oil. R-12 and R-134a oils are different. Mixing them will cause separation and lack of lubrication in the compressor.

A/C System Service Rules

When servicing an air conditioning system, remember to follow these basic rules:

- Inspect the system for obvious problems (loose or missing belt, clogged condenser fins, disconnected wires, inoperative compressor clutch, etc.).
- Check the sight glass to see if the system has a refrigerant charge.
- Feel hose temperatures to determine if the compressor pump is moving refrigerant through the system.
- Leak test the system.
- Wear safety glasses and gloves when servicing a refrigerant system.
- Discharge the system into a recovery unit, never into the air.
- Make sure the system is fully discharged before attempting to remove any pressurized component.
- After disconnecting fittings, cap them to prevent moisture from entering the system.
- Coat all O-rings with refrigerant oil before installation. Add oil to the system as needed.
- Torque all fittings to specifications.
- Evacuate the system and check for leakage (vacuum drop) before charging.
- Charge the system with the correct amount and type of refrigerant.
- Add refrigerant to the suction side of the system with engine running. Do not let liquid refrigerant enter the compressor.
- Use service manual instructions and specifications for system test pressures, temperatures, capacities, and other information.
- Recheck system operation after service.

Heater Service

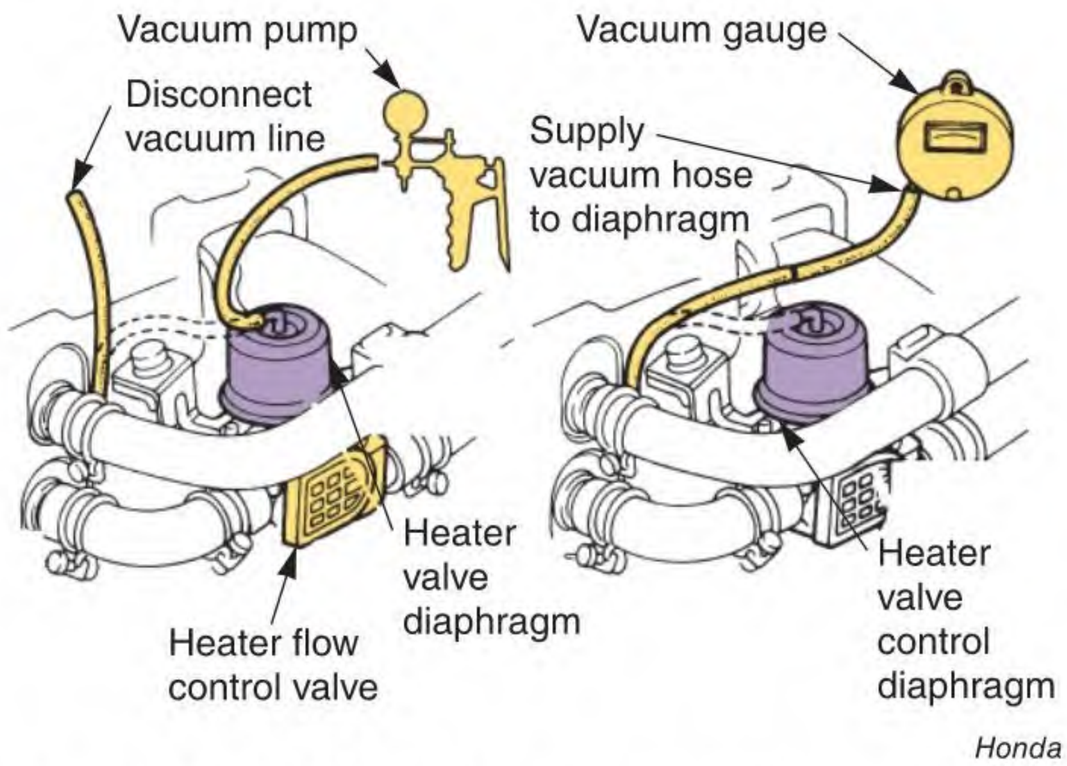
Heater problems typically show up either as coolant leaks or as insufficient warming of the passenger compartment. The heater hoses can harden, break, or leak, especially when they are routed near the hot engine. The heater core can rust and develop leaks, allowing coolant to drip on the car's floor or carpet.

When the system does not produce heat, the heater core may be clogged, a heater hose valve may be inoperative, or the air control doors may not be functioning properly.

Checking Heater Coolant Flow

To check heater coolant flow, let the engine and the heater hoses cool. Then, start the engine and operate it at a fast idle. Turn the heater on high.

As the engine coolant warms, feel both the inlet and outlet heater hoses. Feel the hose on both sides of the heater flow control valve, if used.



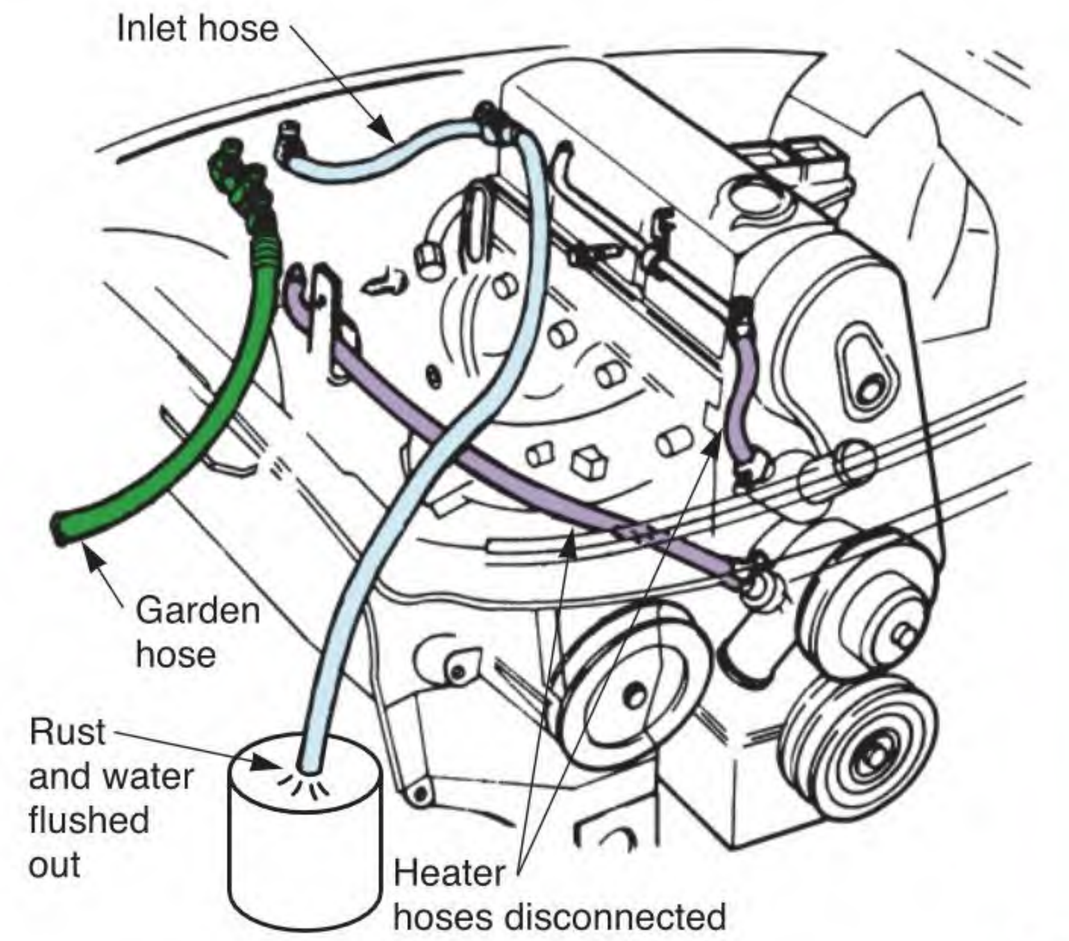
If both heater hoses are about the same temperature, coolant is passing through the heater core and valve. If one hose is hot and the other is cool, there is blockage in the system. The heater core may be clogged or the flow valve may be stuck closed.

To check the operation of a heater flow valve, use a hand vacuum pump to apply suction to the diaphragm. When vacuum is applied, the valve should activate. If the valve does not move or the diaphragm does not hold vacuum, replace it. If the valve and diaphragm are good, use a vacuum gauge or your finger to check that vacuum is reaching the unit through the supply line. See **Figure 84-26**.

Flushing the Heater Core

The heater core can become clogged with rust deposits, which prevents coolant from circulating and reduces heater efficiency. This problem can result from a poorly serviced engine cooling system.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 84-26. The heater flow valve can stick open or closed and the vacuum diaphragm can rupture. A—Use a vacuum pump to check valve operation. B—Also check that vacuum is being fed to the diaphragm from the vacuum line.

To flush the heater core, remove both heater hoses. Connect a garden hose to the outlet heater hose. Turn the hose on and let water force rust out of the core for about five minutes, **Figure 84-27**.

Heater Core Replacement

A clogged or leaking heater core must be replaced. Before removing a heater core, drain the cooling system to a level below the heater core. Then, remove the heater hoses from the heater core. Some heater cores come out from under the dash, while others are removed from the firewall through the engine compartment. Small clips or screws usually secure the housing around the heater core. Some heater cores can be difficult to reach, and a light and mirror are needed to find them. Refer to service literature for exact heater core replacement procedures for the vehicle being serviced.

Ford

Figure 84-27. A clogged heater core is common. Remove the heater hoses. Attach a garden hose to the outlet heater hose and force water through the core and flush out rust.

Blower Motor Replacement

A bad blower motor does not properly circulate air through the passenger compartment, and may produce dry bearing whining or screeching sounds.

Service Procedure

To replace a blower motor:

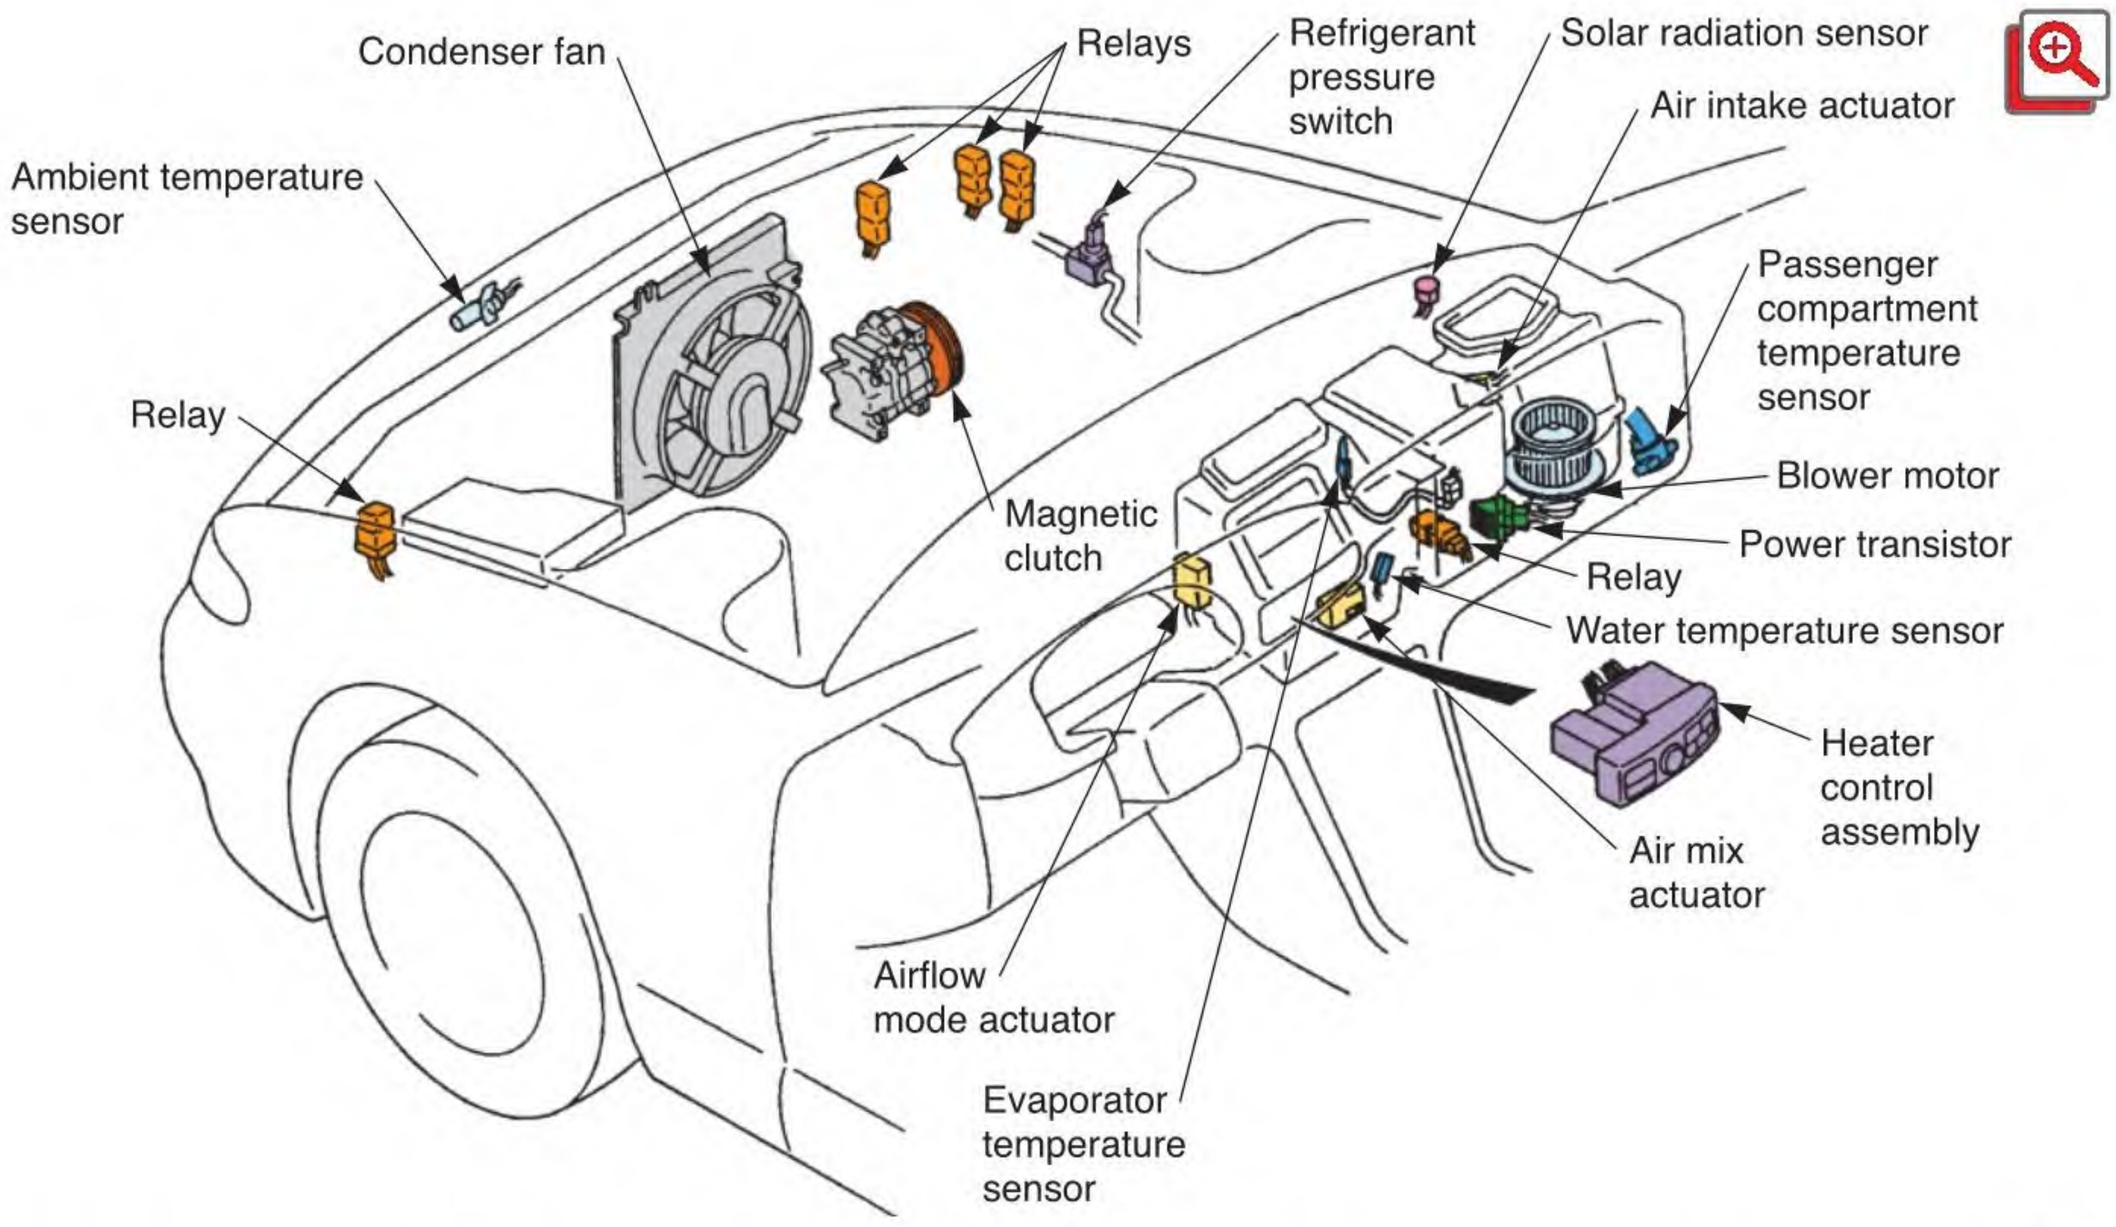
1. Disconnect the battery to prevent short circuits, as well as injuries caused by accidentally energizing the fan.
2. Refer to the service data to find out if the blower motor is removed from under the dash or from outside the firewall.
3. If the blower motor is mounted under the dash, remove inner trim pieces, ducts, and hoses to gain access to the motor mounting screws. You may have to remove the dash glove box or the whole dash panel to get at some blower motor and fan assemblies.
4. On a full-size truck, the blower motor is often removed from inside the engine compartment. The blower motor is held onto the cowl or firewall with machine screws. See **Figure 84-28**.
5. Unplug the harness and remove the blower mounting screws.
6. Lift the blower motor out of its plastic housing.
7. If needed, remove the fan from the old blower motor and install it on the new motor. Make sure the plastic fan is not cracked or broken. A friction clip usually secures the plastic fan to the motor shaft. Make sure the fan is tight and secure on its shaft to prevent it from coming loose.
8. Snug down the blower motor mounting screws and reconnect the wiring.
9. Operate the blower fan at all speeds to make sure it operates quietly. If you hear a loud grinding noise, the fan is not centered on its mount and is rubbing inside its housing.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 84-28. On this pickup truck, the blower motor is easily accessed in the engine compartment.

Checking Air Control Doors

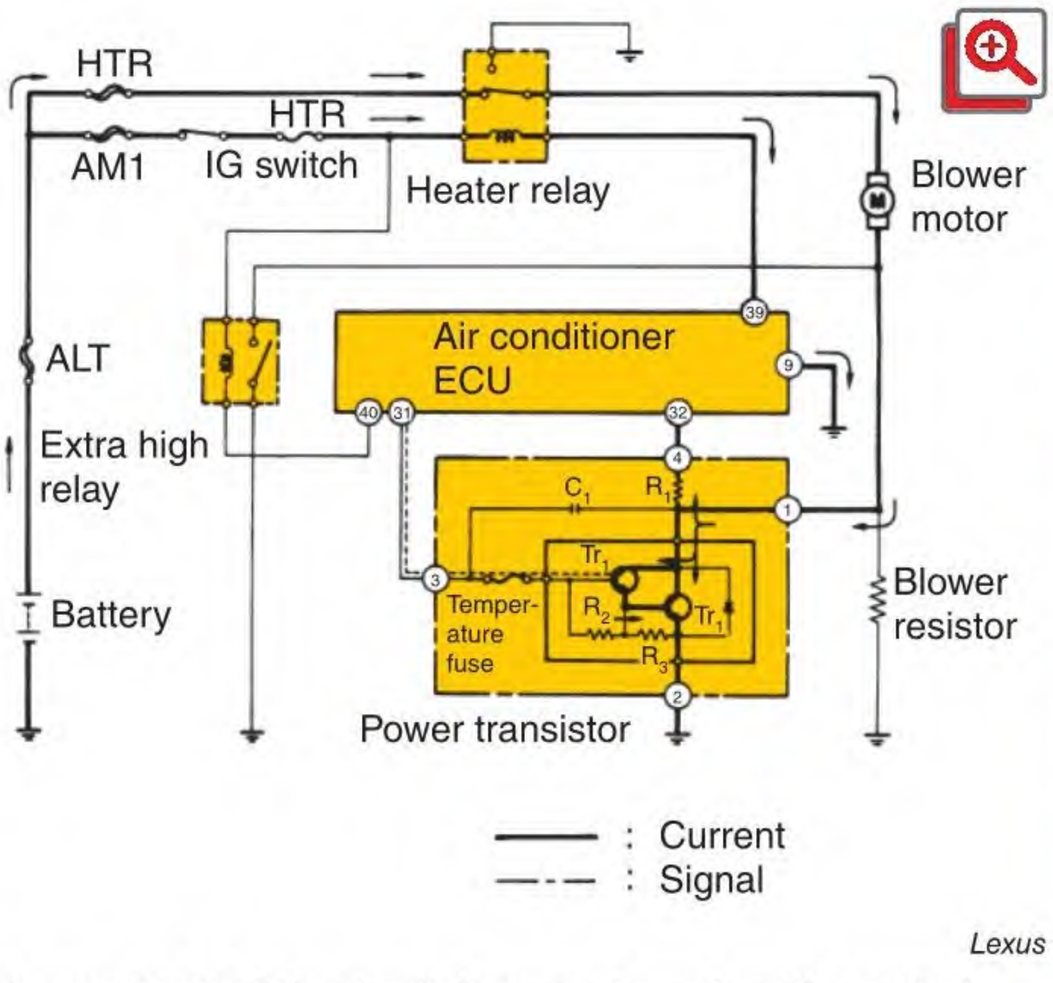


Inoperative air control doors prevent both cool and warm air from flowing through the desired vents. Use service manual diagrams of the doors to determine which ones are not working normally. You can sometimes lay under the dash and watch the air door shaft turn to check operation. If needed, adjust the air control door arm or cable until it closes and opens as needed.

Electronic Climate Control Service

Electronic climate control service can be challenging because there are so many design variations. Again, the service manual will give essential service information.

A ***component location drawing*** shows which parts affect heating and A/C operation and gives the general location of these parts on the vehicle. See **Figure 84-29**.



Wiring diagrams are also needed to troubleshoot electronic climate controls. These diagrams let you trace wires from component to component, **Figure 84-30**.

Mazda

Figure 84-29. A component location drawing shows the location of all major parts in climate control system. This can save time when troubleshooting.

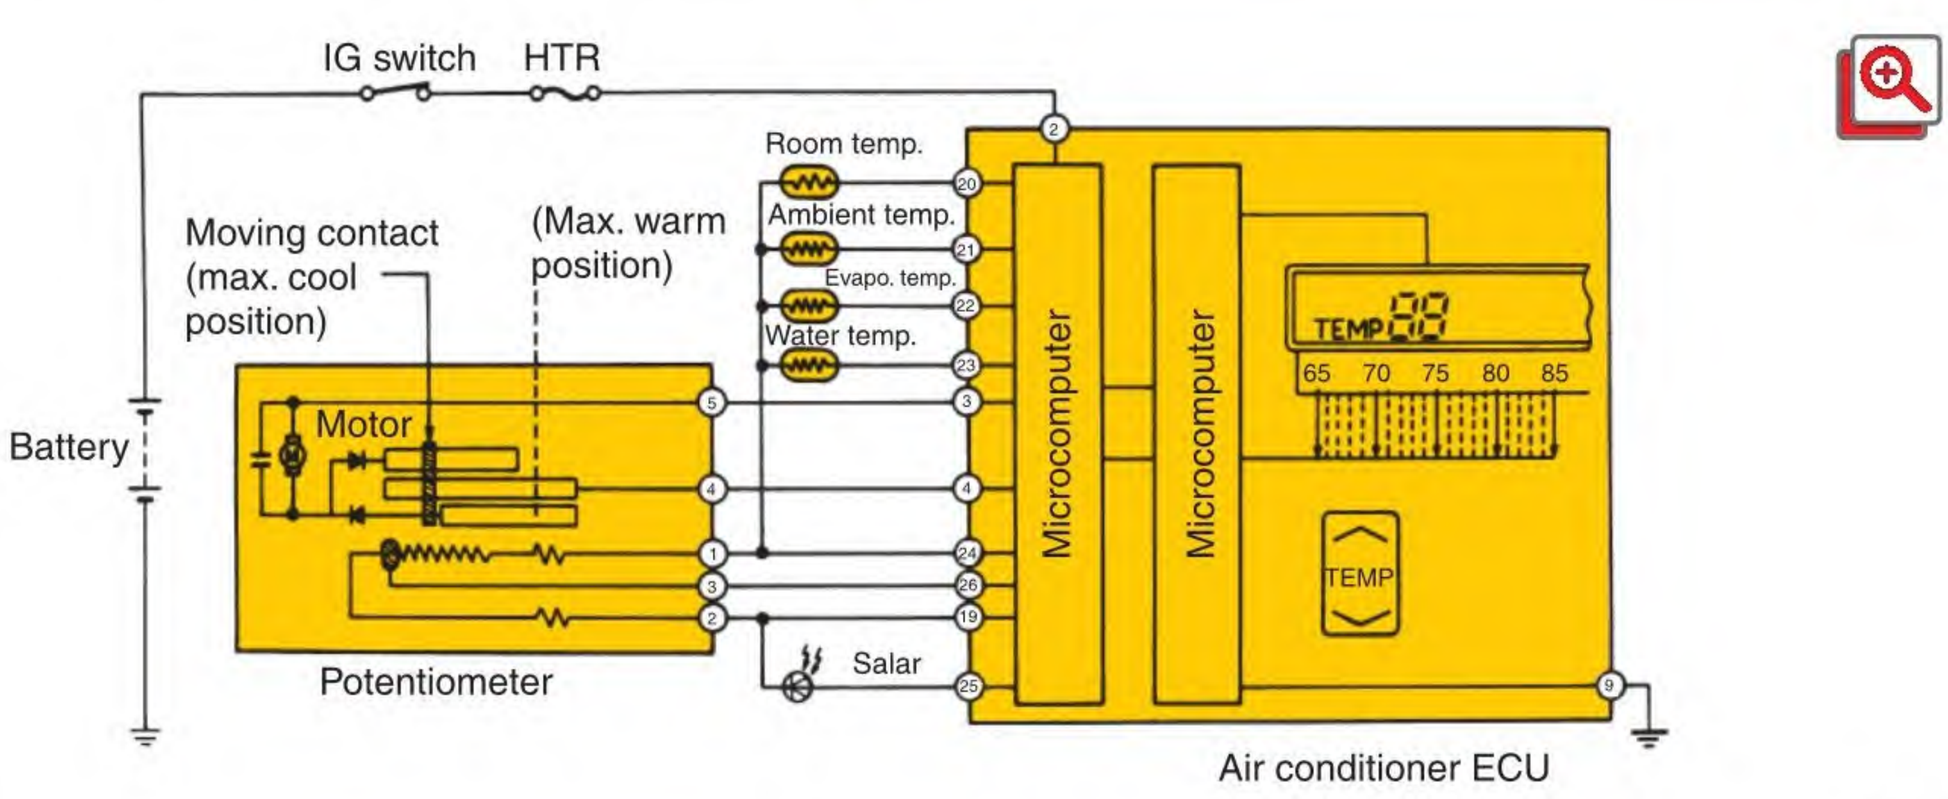
Copyright Goodheart-Willcox Co., Inc.

Lexus

Figure 84-30. This circuit diagram shows how the control module can control blower speed. This principle is used in other system designs.

The control module is the brain of modern electronic climate control systems. To check its condition, you must determine if the unit is producing the right outputs for known inputs. For example, if you move the controls to the maximum heat position, the module should produce an output to move the correct air control door to route warm air into the passenger compartment.

The control module must also produce the correct readouts in the digital display. Various sensors provide feedback so that the module can control the climate control system and produce meaningful displays, **Figure 84-31**.

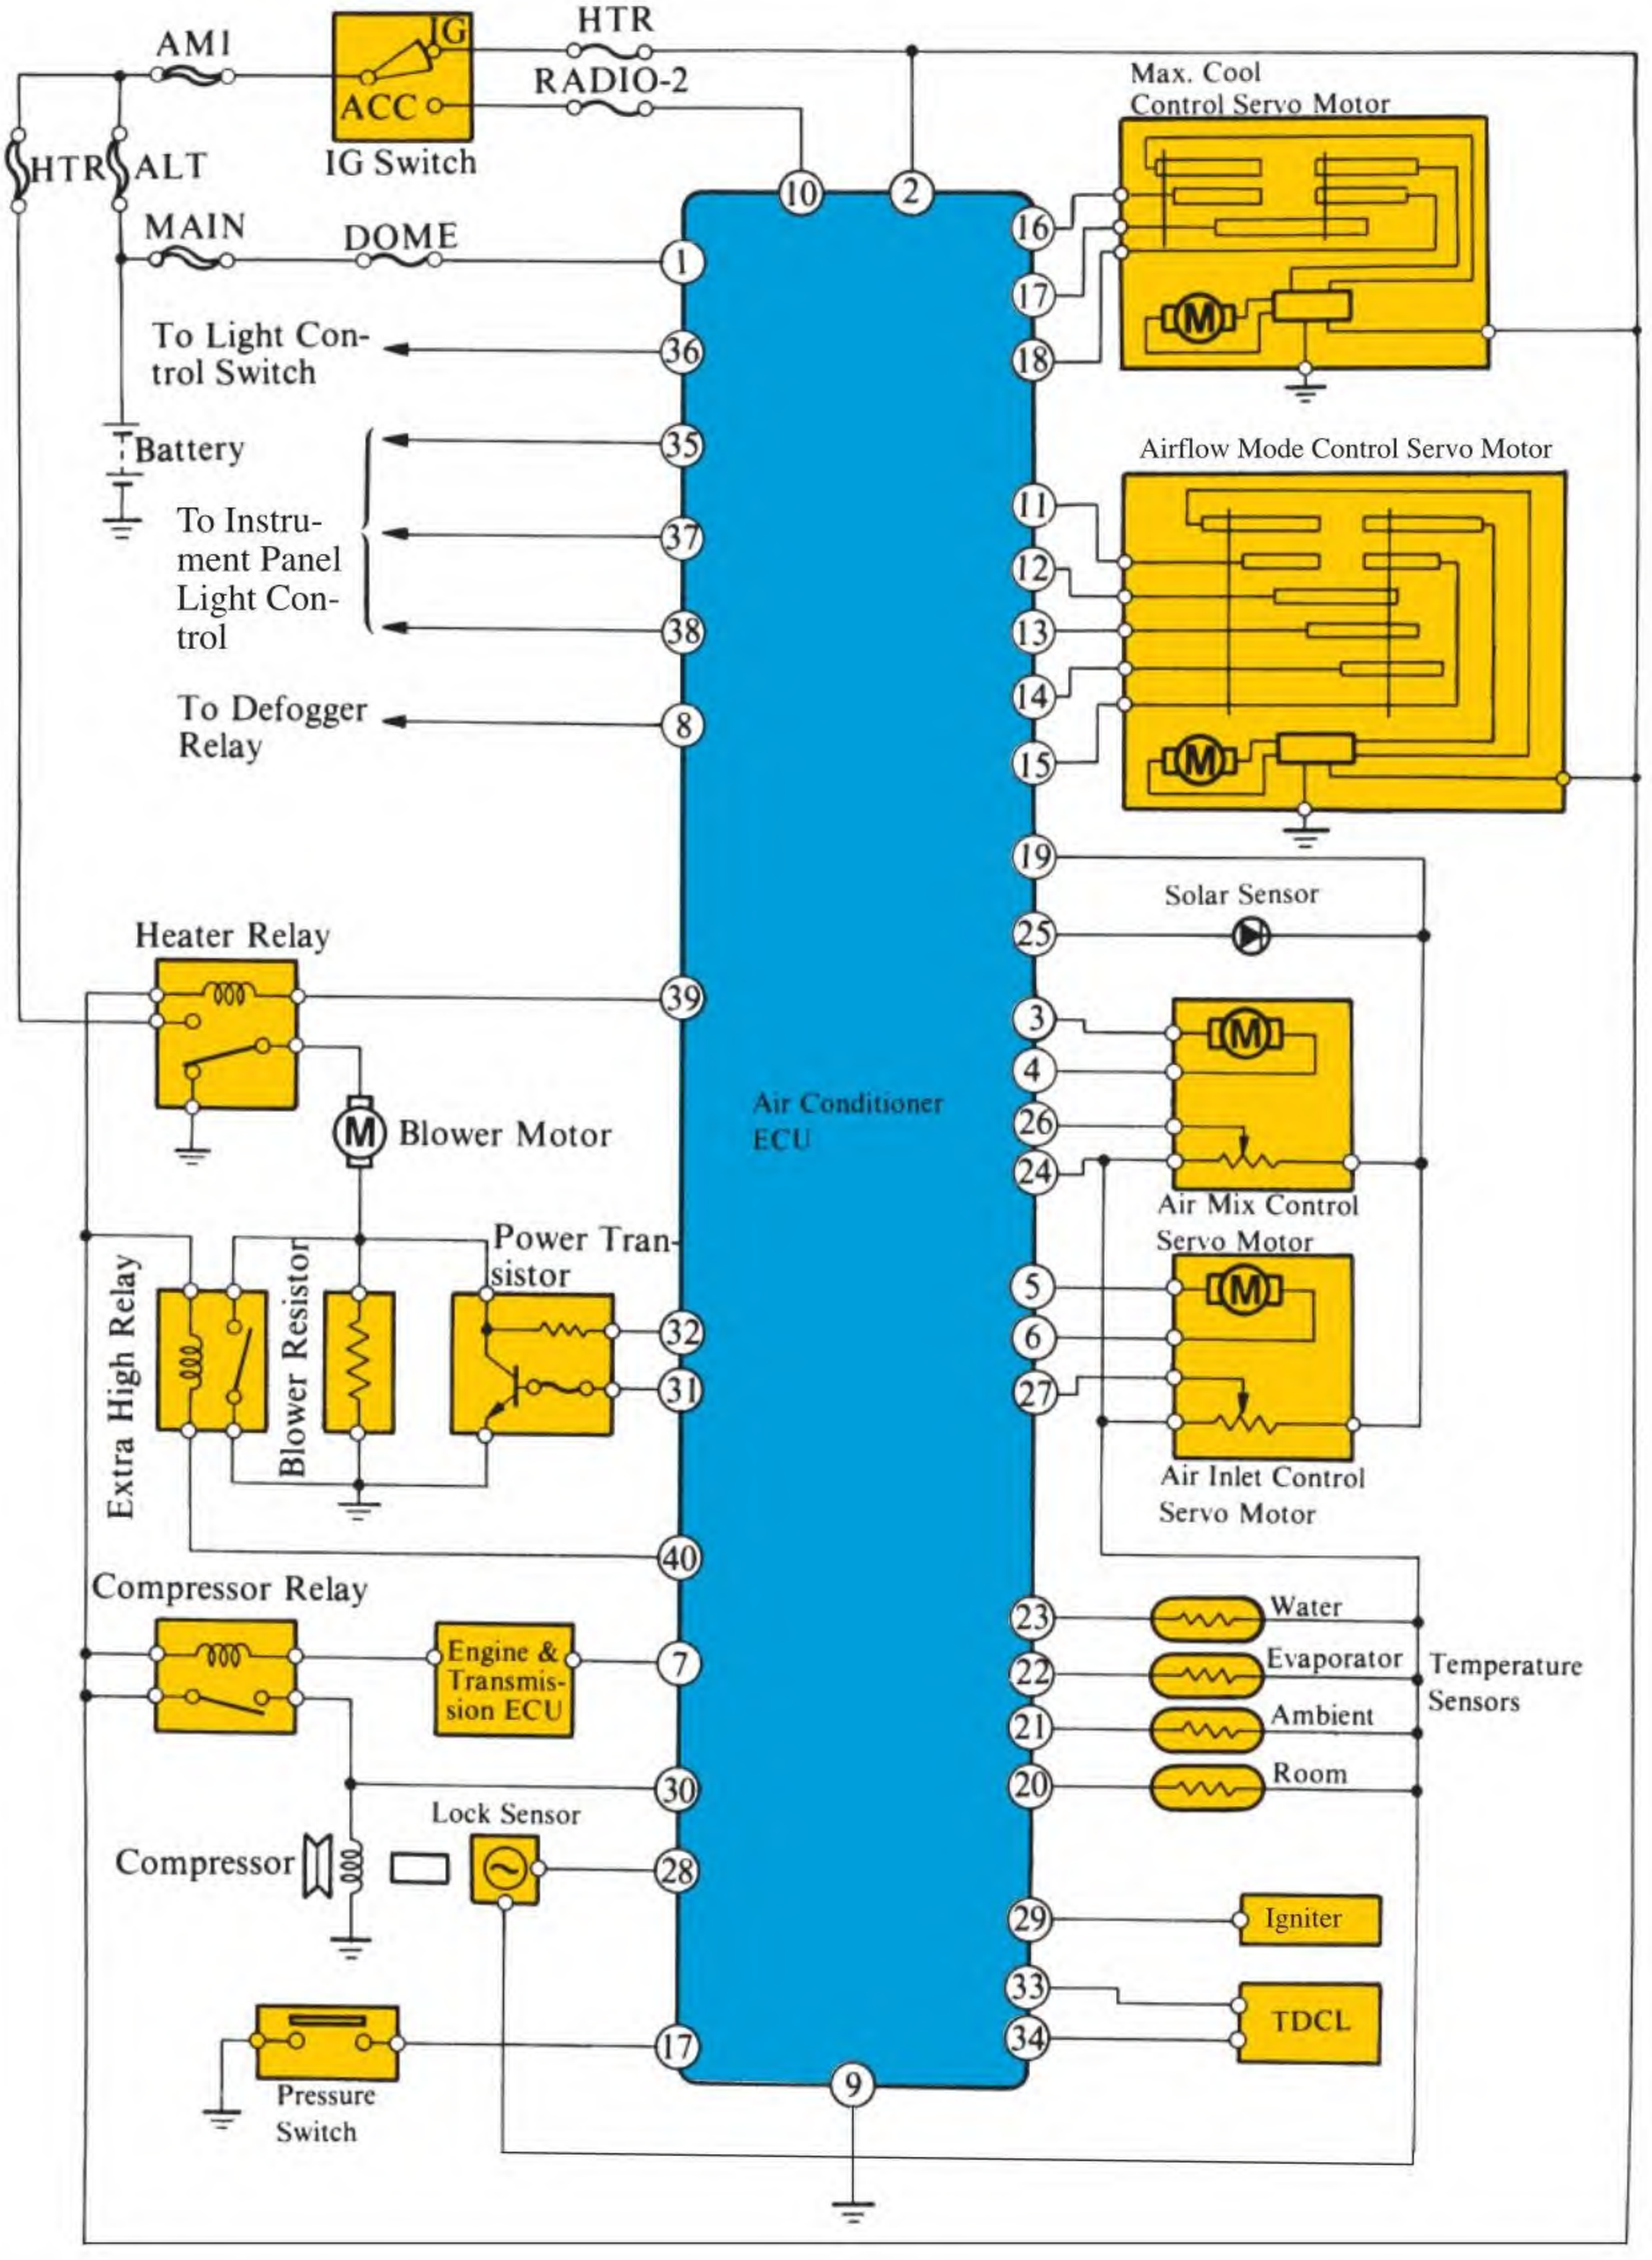


A wiring diagram for a complete climate control system is shown in **Figure 84-32**. Refer to this type of diagram when diagnosing and repairing hard-to-find problems.

Diagnostic Case Study

Concern: Mr. Watt brings his 2004 Impala to the shop. He states that his air conditioning system is not blowing as cold as usual.

Cause: Duff starts the engine and sets the air conditioner controls to high cool. He notes that the air coming from the vents is not as cool as it should be. Looking under the hood, Duff sees that the compressor belt is intact, but the compressor is turning on and off rapidly. Duff then checks the temperature of the air conditioner lines. The low side feels warm, while the high side feels cooler than it should. Duff shuts off the engine and turns the vehicle over to the shop's air conditioning technician.



After allowing the vehicle to sit for about an hour, the technician connects a pressure gauge set to the vehicle's service valves to measure static pressure. The gauge shows approximately 30 psi (210 kPa), which indicates that some refrigerant has leaked from the system. The technician uses an electronic leak detector to search for leakage points. The detector sounds off near the compressor's front seal. The technician sweeps the entire system and finds only the leak at the compressor seal.

Lexus

Figure 84-31. This circuit shows how two microprocessors are used to operate the digital display and to analyze inputs from various sensors and switches.

Lexus

Figure 84-32. Wiring diagram for a modern climate control system. Note the various inputs from sensors and outputs to motors and displays.

Copyright Goodheart-Willcox Co., Inc.

Correction: The technician connects the refrigerant recovery system to the vehicle and pulls the refrigerant from the system. He replaces the front seal in the compressor and then evacuates the system, which holds vacuum for an hour.

The technician charges the system with the correct amount of refrigerant. He sets the air conditioning controls to high cool and closes the windows. He places a thermometer in the center vent of the dash. After a few minutes of operation, the thermometer reads approximately 50°F (10°C). The car is released to the owner.

Summary

- Late-model climate control systems produce trouble codes if the on-board diagnostic system detects an abnormal circuit value or condition.
- To check the basic action of the A/C system, start the engine. Turn the air conditioning system on high and allow it to run for about ten minutes. Then, feel the refrigerant lines.
- During visual checks of the A/C system, be sure to inspect the sight glass (if used).
- Refrigerant can cause severe *frostbite* if it contacts your skin.
- Always wear safety glasses when working with refrigerant.
- Keep refrigerants away from excessive heat.
- Keep refrigerant away from an open flame.
- Never discharge refrigerant into the air.
- A pressure gauge assembly typically consists of two pressure gauges, a manifold, two on-off valves, and three service hoses.
- A Schrader service valve is a spring-loaded valve, similar to the air valve in a tire.
- An R-134a service valve has a quick-disconnect fitting that accepts a corresponding fitting on the R-134a gauge set service hose.
- A performance test indicates air conditioning system condition by measuring cooling vent temperatures as well as system pressures with the engine running.
- With R-134a, some manufacturers require you to measure wet- and dry-bulb temperatures at the blower inlet. This will let you use a chart to find the relative humidity, which affects system operation and pressures.
- An electronic leak detector uses a special sensor and an electronic amplifier to locate refrigerant leaks.
- Since refrigerant can no longer be discharged into the air when servicing air conditioning systems, technicians must use a refrigerant recovery unit.
- The compressor shaft seal is a common refrigerant leakage point.
- A bad condenser can leak refrigerant or it can become restricted internally.
- A faulty expansion valve will usually show up as low suction (low-side) or discharge (high-side) pressure readings.
- A clogged orifice tube will produce symptoms similar to those caused by a restricted expansion valve.
- A bad thermostat will usually keep the compressor clutch from engaging and prevent the A/C system from cooling.
- A/C system evacuation involves using a vacuum pump to remove air and moisture from the inside of the vehicle's refrigerant system.
- A/C system charging involves filling the system with the correct amount and type of refrigerant.
- A charging station usually contains a vacuum pump, a pressure gauge set, an oil injection cylinder, and a refrigerant container.
- Make sure you are using the right type of compressor oil. R-12 and R-134a oils differ.
- Heater problems typically show up as coolant leaks or as insufficient warming of the passenger compartment.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

A/C system charging
A/C system evacuation
bubble detector
bubbling sight glass
charging station
clear sight glass
cloudy sight glass
component location
drawing
compressor clutch
compressor shaft seal
dust caps
electronic leak detector
evaporator drain
internally charged detector
manifold gauge assembly

Copyright Goodheart-Willcox Co., Inc.

oil-streaked sight glass
performance test
pressure gauge assembly
refrigerant recovery machine
Schrader service valve
service valves
static A/C pressure reading
torch detector

Activities

1. Talk to the owners of several shops that service auto air conditioners. Ask if they convert R-12 systems to R-134a and what is involved. Report the findings to your class.
2. Demonstrate the proper connections and use of a gauge manifold set for making a static pressure reading on an A/C system.
3. Create a video demonstrating the proper use of an electronic refrigerant leak detector.
4. Locate the refrigerant storage containers in your shop. Are they in good condition and stored in an appropriate location? Write a short report summarizing your findings and explaining the environmental and physical dangers posed by improper refrigerant storage.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List six check points when inspecting an air conditioning system.
2. How can feeling line temperatures help you when inspecting an air conditioning system?
3. Which of the following sight glass conditions could indicate system troubles?
   (A) Clear sight glass.
   (B) Bubbling sight glass.
   (C) Cloudy sight glass.
   (D) All of the above.
   (E) None of the above.
4. Explain five important safety precautions for air conditioning system service.
5. What is a pressure gauge assembly, or manifold assembly?
6. _____ valves provide a means of connecting the pressure gauge assembly for testing, discharging, evacuating, and charging the system.
7. Describe a Schrader valve.
8. A static A/C pressure reading will indicate whether the compressor is in good condition. True or False?
9. Why is an electronic leak detector safer than a torch type detector?
10. Give a reason why you should not discharge (empty) an A/C system into the air.

ASE-Type Questions

1. An automotive air conditioning system is not cooling properly. Technician A checks for a loose compressor drive belt. Technician B looks for blockage in the condenser fins. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. An automobile's air conditioning is running on high. Technician A says the refrigerant lines on the high-side of this system should be warm or hot. Technician B says the refrigerant lines on the high-side of this system should be cool. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. An automobile air conditioning's low-side line is cold, but the system does not cool. Technician A says this problem may be caused by faulty air control doors. Technician B says this problem may be caused by an instrument panel control malfunction. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. The condition of a car's air conditioning refrigerant needs to be checked through the system's sight glass. Technician A says the sight glass may be located on top of the receiver-drier. Technician B checks to see if the sight glass is located in a refrigerant line. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

5. An automotive air conditioning system's sight glass is clear. Technician A says a clear sight glass normally indicates that the system has the correct charge of refrigerant. Technician B says a clear sight glass may indicate an empty system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Bubbles are visible in an air conditioning system's sight glass. Technician A adds refrigerant to the system. Technician B removes some of the refrigerant from the system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. The sight glass on an auto air conditioning system appears to be "cloudy." Technician A checks the condition of the system's receiver-drier. Technician B says the system is operating properly. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. A car's A/C system is being serviced. Technician A places a shop rag around the fitting before removing a refrigerant line. Technician B wears safety glasses while removing a refrigerant line. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A uses the high-pressure gauge on a manifold assembly to measure the compressor discharge pressure. Technician B uses the high-pressure gauge on a manifold assembly to measure the A/C's suction-side pressure. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. During a static A/C pressure test, the manifold assembly's high-pressure gauge shows approximately 50 psi. Technician A says this reading indicates a very low refrigerant level in the system. Technician B says this reading indicates an adequate amount of refrigerant in the system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. All of the following are used to detect automotive A/C system leaks, *except*:
    (A) Bubble detector.
    (B) Torch detector.
    (C) Electronic leak detector.
    (D) Tube detector.
12. Moisture is found in an automotive air conditioning system. Technician A replaces the receiver-drier. Technician B removes refrigerant from the system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. A car's air conditioning system is not operating properly. Pressure gauge readings show a low high-side pressure and a high low-side pressure. Technician A says the expansion valve may be restricted. Technician B says the expansion valve may be stuck in the open position. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. An automotive air conditioning system needs to be charged. Before charging this system, Technician A tests the system for leaks. Before charging this system, Technician B evacuates the A/C system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
15. An automobile's heater system will not operate. Technician A checks for a clogged heater core. Technician B checks the operation of the heater hose valve. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Section 15

Safety Systems and Future Technologies

Chapter 85
Restraint System Technology

Chapter 86
Restraint System Service

Chapter 87
New and Future Technology

Every year, automakers strive to incorporate features into their vehicles that improve safety, efficiency, and convenience. These features include highly effective restraint systems that protect a vehicle's occupants during an accident.

It is critical that you understand the operation and repair of the restraint systems found on late-model vehicles. Chapters 85 and 86 cover the operation, diagnosis, service, and repair of various restraint systems, including seat belt systems and air bag systems.

Chapter 87 details many of the cutting-edge technologies used in late-model vehicles. It also discusses exciting high-tech systems that may become common in the not-too-distant future.

Chapter 85
Restraint System Technology

After studying this chapter, you will be able to:

- Explain how vehicle body and frame construction works with restraint systems to protect a vehicle's occupants.
- Describe the purpose of restraint systems.
- Identify and locate the most important parts of vehicle restraint systems.
- Describe restraint system design variations.
- Correctly answer ASE certification test questions requiring a knowledge of restraint system operation and construction.

Restraint systems hold a vehicle's occupants in their seats, protecting them from injury during an automobile accident. These systems include the seat belts and air bags. Restraint system designs are affected by the strength and collapsibility of the vehicle's body structure, frame members, roof pillars, steering column, and dashboard.

The ability of a properly functioning restraint system to save lives makes it very important that you understand the operation and repair of these systems. Understanding how restraint systems work will help you diagnose problems when a system malfunctions.

Vehicle Collisions

Vehicle collisions, or ***accidents***, normally result from driver error that causes the car or truck to hit other objects (vehicles, trees, retaining walls, etc.). Tremendous force is generated when the vehicle, which can weigh almost two tons, crashes to a halt in a few feet (or meters) of travel. Automobile manufacturers design their vehicles to absorb this force in a controlled manner. Refer to **Figure 85-1**.

Crush zones located at the front and rear of the body-frame assembly are designed to collapse during a severe impact. As the crush zones collapse, they absorb some of the collision forces rather than transferring them to the passenger compartment. The passenger compartment is stiffer and stronger than these crush zones, so the occupants are protected from the forces of the accident. See **Figure 85-2**.

Side-impact beams, made of high-strength steel or carbon fiber, are mounted in the vehicle's doors to help prevent intrusion into the passenger compartment.

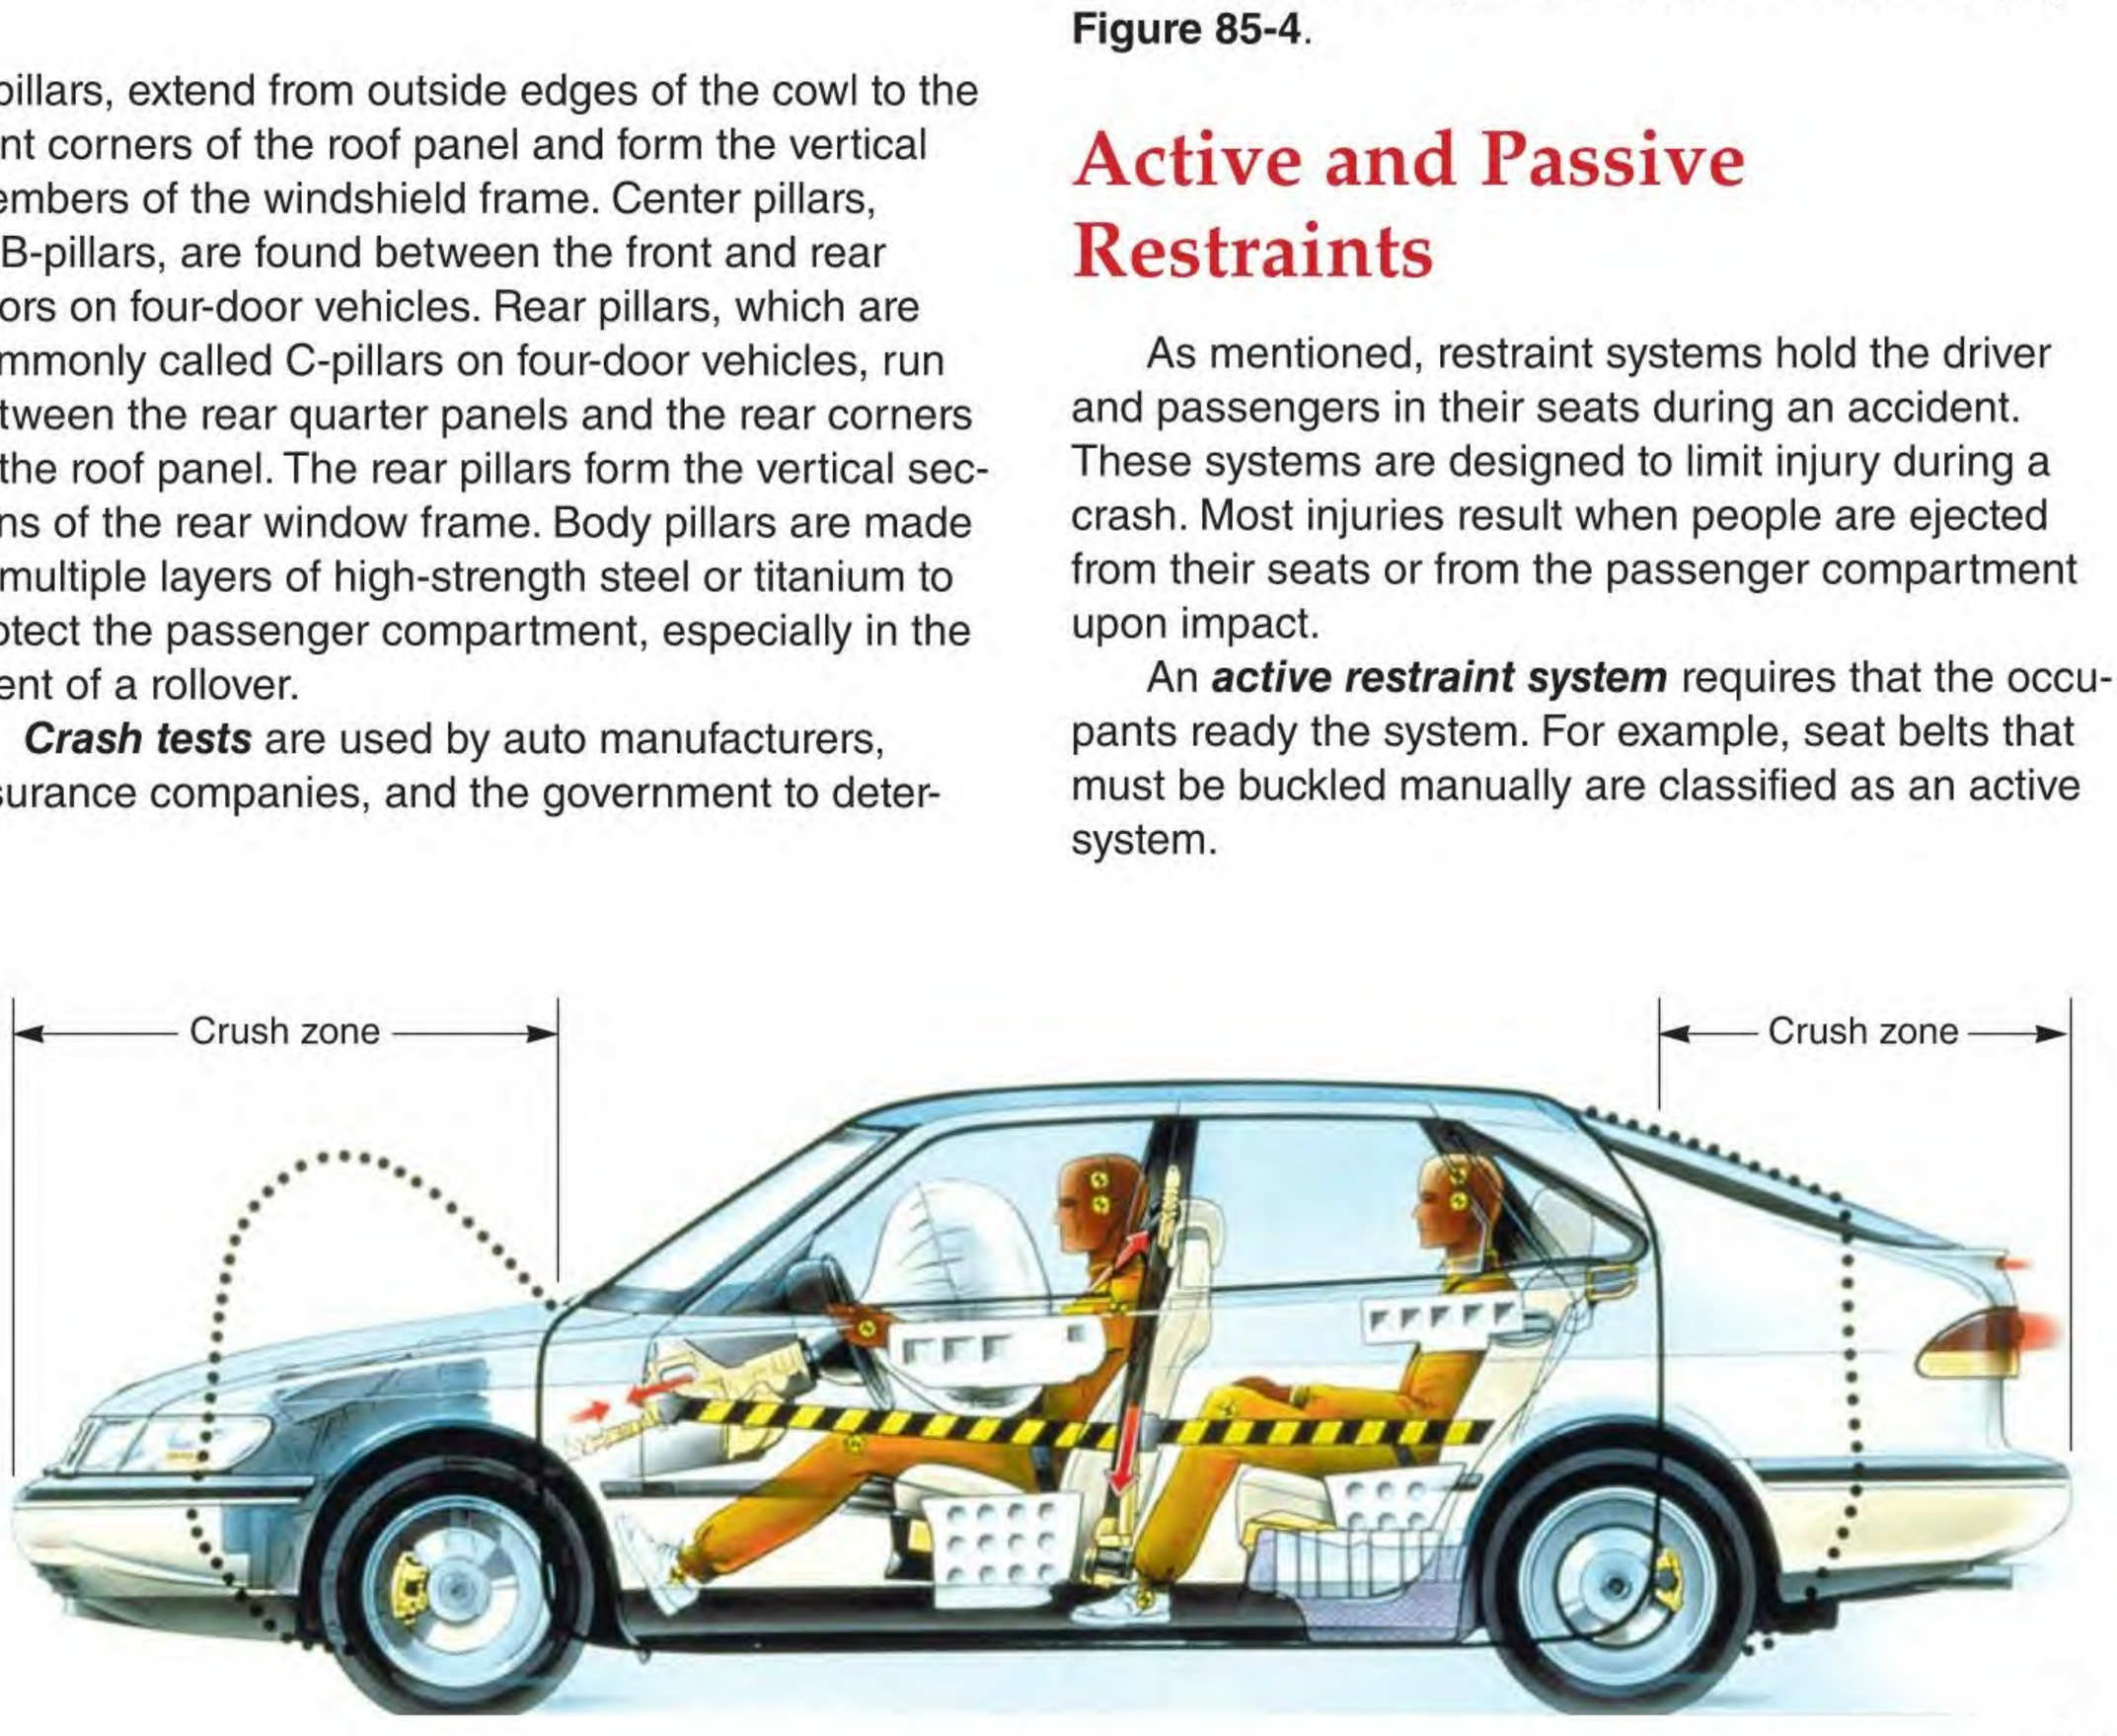
Body pillars are the metal beams that extend vertically to support the roof panel. Front pillars, or

Copyright Goodheart-Willcox Co., Inc.

Chrysler

Figure 85-1. When a passenger vehicle hits a large, stationary object, a tremendous amount of energy is absorbed to bring the vehicle to an abrupt, but controlled, halt.

A-pillars, extend from outside edges of the cowl to the front corners of the roof panel and form the vertical members of the windshield frame. Center pillars, or B-pillars, are found between the front and rear doors on four-door vehicles. Rear pillars, which are commonly called C-pillars on four-door vehicles, run between the rear quarter panels and the rear corners of the roof panel. The rear pillars form the vertical sections of the rear window frame. Body pillars are made of multiple layers of high-strength steel or titanium to protect the passenger compartment, especially in the event of a rollover.



Crash tests are used by auto manufacturers, insurance companies, and the government to determine how well a vehicle's body-frame structure and restraint systems will protect its occupants in the event of a major collision. Vehicles are crashed into stationary walls or other vehicles to measure how the vehicles and their occupants withstand and react to the impact forces. Crash tests are performed from the front, side, and rear of the vehicle. This allows the effects of major impact forces from each direction to be studied. See **Figure 85-3**. Vehicles are rated as good, acceptable, marginal, or poor based on front and side crash tests, as well as rollover tests.

Crash test dummies are used to measure the impact forces that would act on the human body during a crash test. Inertia sensors in the test dummies record the forces acting on vital parts of the body. This allows the manufacturer to estimate how badly people will be injured during similar crash conditions. Study **Figure 85-4**.

Active and Passive Restraints

As mentioned, restraint systems hold the driver and passengers in their seats during an accident. These systems are designed to limit injury during a crash. Most injuries result when people are ejected from their seats or from the passenger compartment upon impact.

An ***active restraint system*** requires that the occupants ready the system. For example, seat belts that must be buckled manually are classified as an active system.

Saab

Figure 85-2. Crush zones are built into the front and rear areas of the vehicle's body and frame. These areas collapse more easily than the passenger compartment, increasing occupant safety. Dotted lines show how the body deforms during a major collision.

Figure 85-3. Automakers perform extensive crash tests to analyze the safety of new car and truck designs. A—Frontal-impact crash test propels the vehicle straight into a barrier. B—In a side-impact crash test, a test sled hits the side and doors of the test vehicle. C—In a rear-impact crash test, the test sled is propelled into rear bumper and trunk area.

Volvo

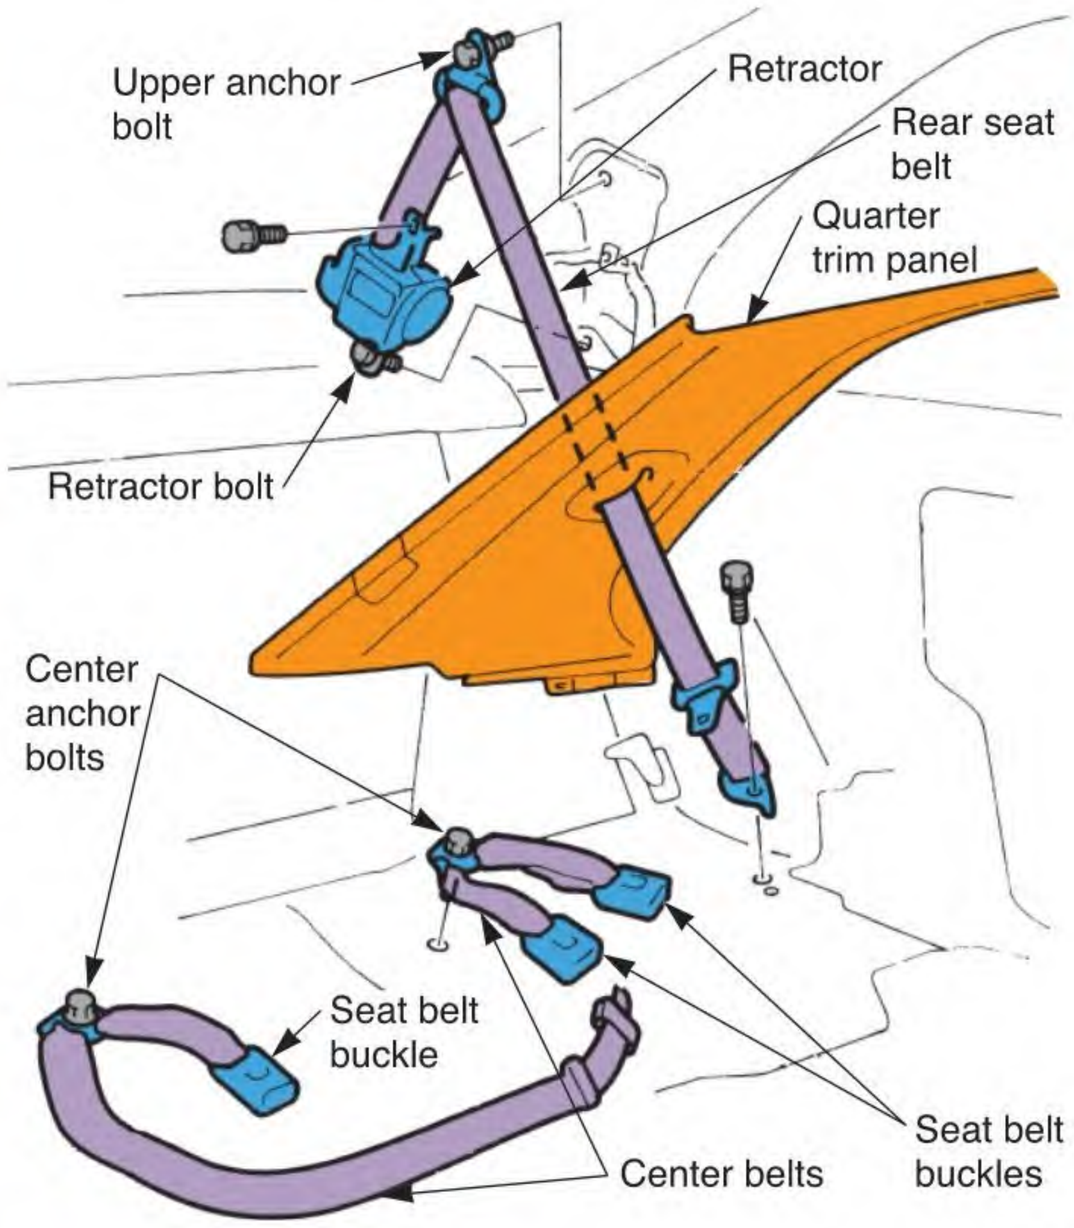
Figure 85-4. A crash test dummy is designed to measure the forces that would act on the human body during an auto accident. Damage to the dummy indicates how badly people would be injured in a similar accident.

A ***passive restraint system*** operates without driver or passenger activation. Air bags and automatic seat belts are passive restraint systems. Refer to **Figure 85-5**.

Seat Belt Systems

Seat belts are strong nylon straps that hold people in their seats during a collision. ***Lap belts*** extend across a person's lap. ***Shoulder belts*** extend over a person's shoulder and chest.

The ***seat belt buckle*** allows you to engage and disengage the belt around your body. ***Seat belt anchors*** provide a means of bolting the seat belt to the car's body and frame structure. A large steel bolt normally secures the seat belt anchors to the structural members in the rocker panels and floor panel. Look at **Figure 85-6**.



Copyright Goodheart-Willcox Co., Inc.

Saab

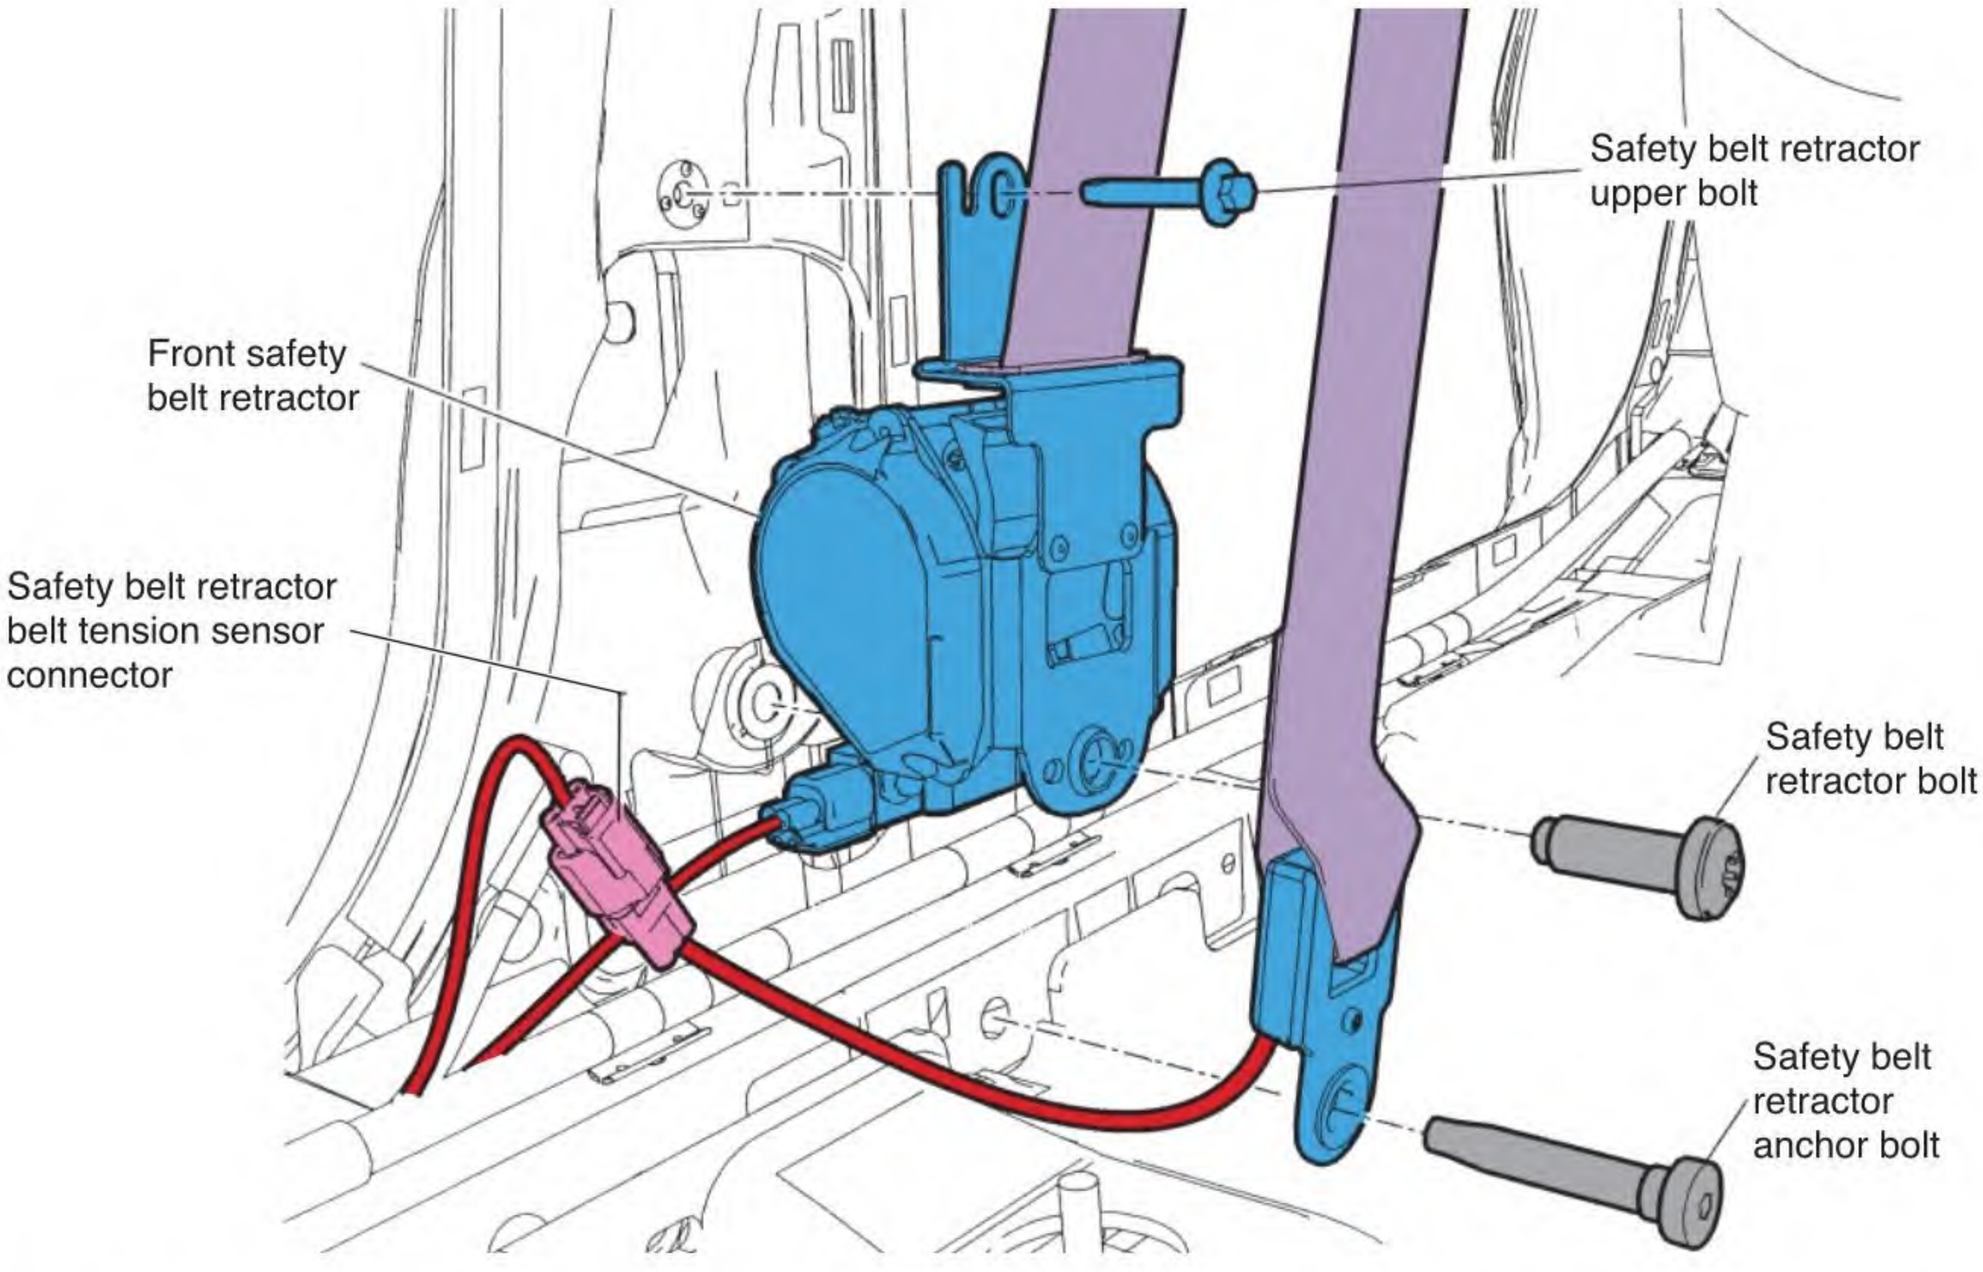


Figure 85-5. Modern vehicles are much safer than those produced in the past. Besides stronger passenger compartments, seat belts and air bags help protect the driver and passengers from injury during collisions.

A ***belt retractor*** takes the slack out of the seat belt so the belt fits snugly around the body. Designs vary. Most pull the belt tight during rapid deceleration, such as when the driver slams on the brakes. See **Figure 85-7**.

Honda

Figure 85-6. Note the basic parts of a seat belt assembly.

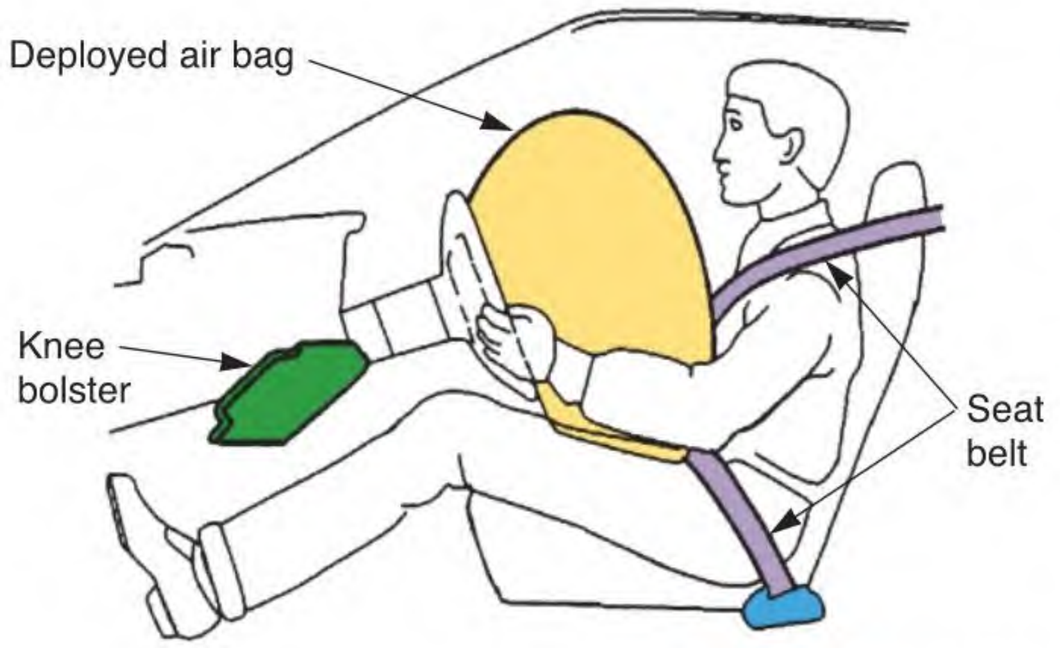
Ford

Figure 85-7. A seat belt retractor pulls the seat belt tight around a person's body during rapid deceleration. Large anchor bolts are used to secure the seat belt assembly to the frame or unibody of the vehicle.

Copyright Goodheart-Willcox Co., Inc.

A ***seat belt reminder system*** activates a dash light and generates an audible tone to warn the vehicle's occupants to buckle their seat belts.

Knee Diverter



A ***knee diverter***, or ***knee bolster***, is formed into the lower part of the dash to protect the driver's and the front passengers' knees from being injured on the metal frame of the dash. The diverter also prevents the driver and passengers from sliding under the air bag during a collision. It is usually a thick plastic panel that covers the metal frame of the dash. Refer to **Figure 85-8**.

Air Bag Systems

An ***air bag system*** deploys inflatable nylon bags to help protect a vehicle's occupants during a collision, **Figure 85-9**. The air bags inflate in about 1/20th of a second, well before a body can fly forward during a collision. The tough nylon bags can easily absorb the forward inertia of a human body. This helps protect both the driver and the passengers. The air bag system is designed to supplement the protection provided by seat belts.

Typical air bag system parts include the following:

- Air bag module—An air bag module contains the inflator mechanism and the nylon air bag that expands to protect the vehicle's occupants during the collision.
- Air bag controller—An air bag controller is a computer that operates the system and detects faults.

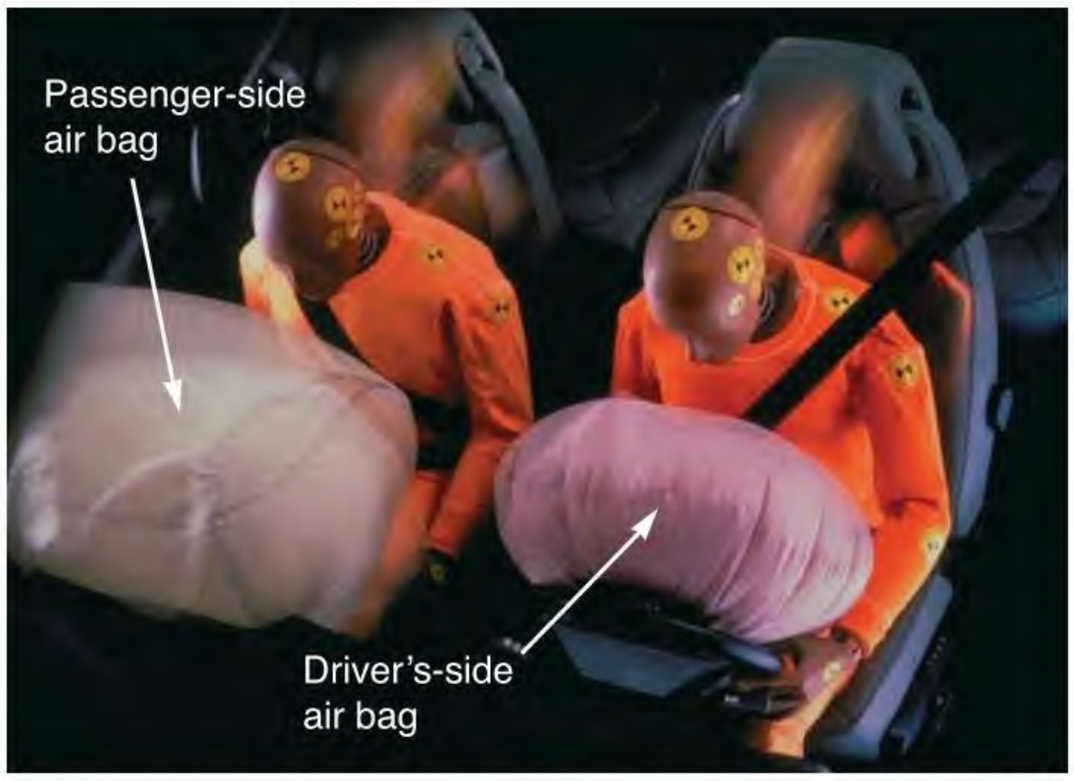
Goodheart-Willcox Publisher

Figure 85-8. This drawing shows the three primary restraint devices: the seat belt, air bag, and knee bolster.

Goodheart-Willcox Publisher

Figure 85-9. This vehicle is equipped with a driver's-side air bag, a passenger-side air bag, side-impact air bags, and side curtain air bags.

- Impact sensors—Air bag impact sensors are inertia sensors that signal the controller in the event of a collision. When at least two impact sensors are energized, the controller activates the air bag module.
- Clock spring—The clock spring is mounted in the steering column and provides a continuous electrical connection between the driver's-side air bag module and the air bag wiring harness in the steering column.
- Dash warning lamp—The dash warning lamp contains a bulb that glows when the vehicle is started and remains on until the system is armed (approximately 5 seconds). The bulb will also glow if the controller has detected a problem in the system.



Air Bag Types

The ***driver's-side air bag*** is located inside the steering wheel and protects the driver from head and chest injury during a high-speed frontal collision. Older vehicles may have a driver's-side air bag only. All late-model vehicles are equipped with dual air bags: a driver's-side air bag and a ***passenger-side air bag***. See **Figure 85-10**.

The passenger-side air bag deploys from the right side of the dash. It is much larger than a driver's-side air bag, since it is relatively far from the passengers and may have to protect two humans simultaneously.

The driver's- and passenger-side air bags will only deploy during frontal impacts. Steering wheel

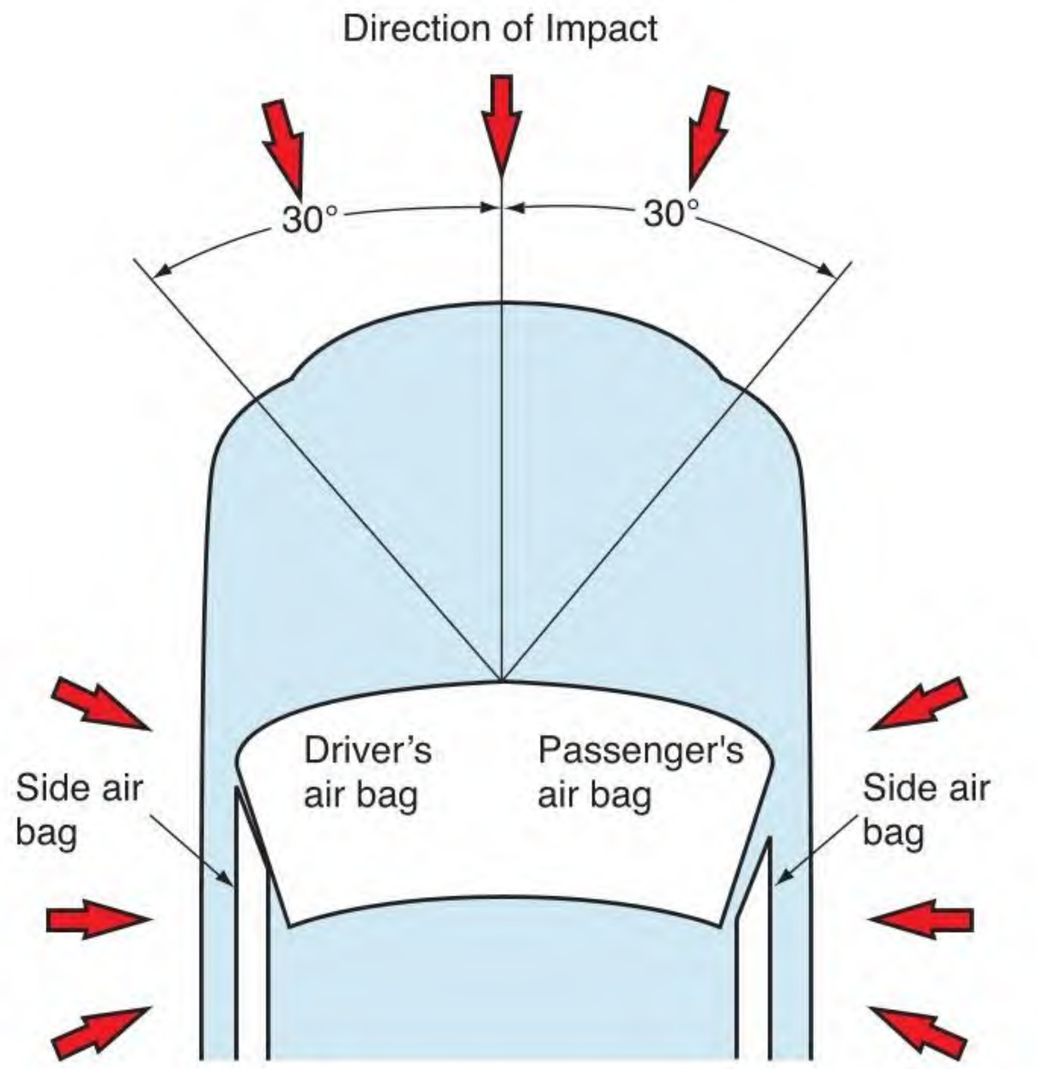
Saab

Figure 85-10. Both driver's-side and passenger-side air bags are shown here. Note that the passenger-side air bag is considerably larger than the driver's-side air bag.

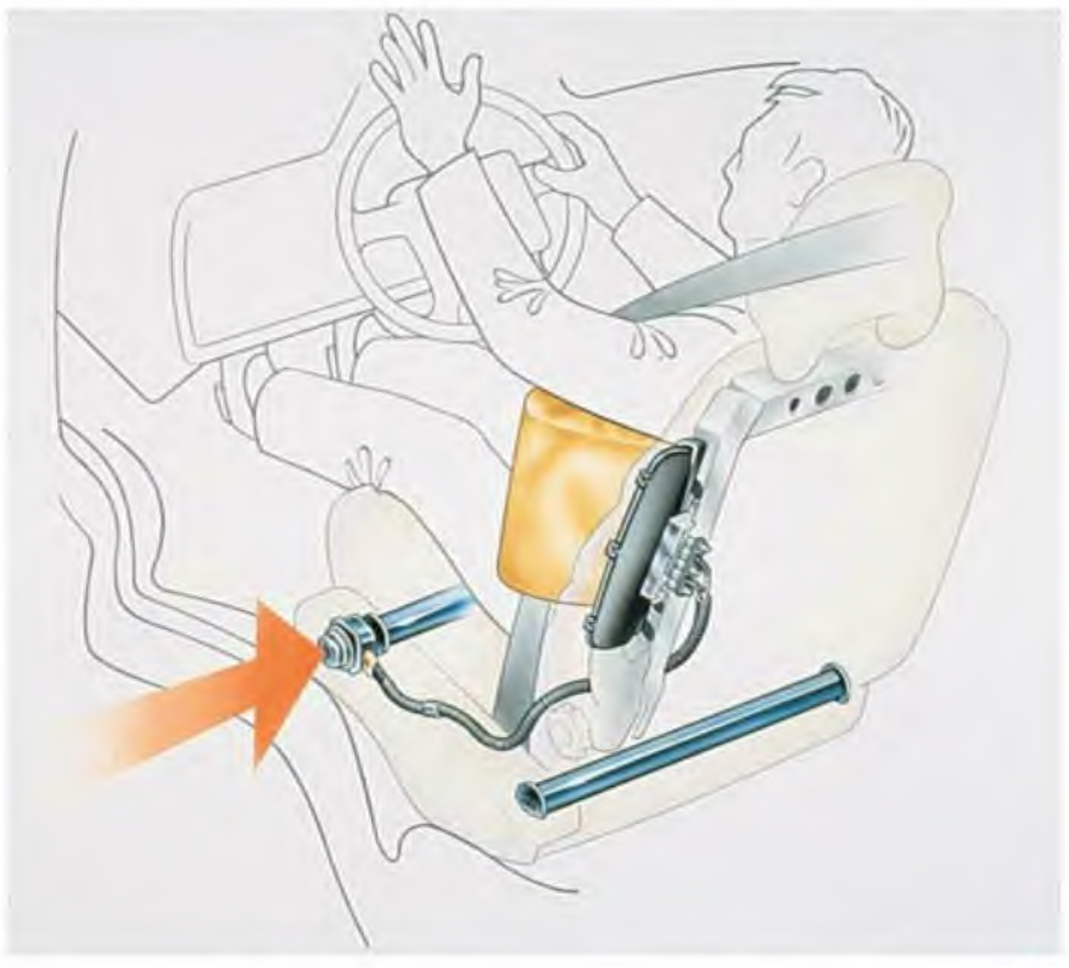
and dash-mounted air bags may not deploy in side impacts, rear impacts, or rollover situations. A collision must occur within about 30° of the vehicle's centerline for these air bags to inflate.



Side-impact air bags can be located in the door panels or on the outside edge of each front seat. These small air bags deploy when the vehicle is hit from the side. They generally do not deploy during a frontal impact. See **Figure 85-11**.

When a vehicle is hit from the side, injury usually results when the occupant's shoulder and head fly through the side window glass. A side-impact air bag system senses the side thrust of the impact and deploys a small air bag to cushion the person as he or she is propelled sideways, **Figure 85-12**.

Side curtain air bags are designed to drop down like "curtains" over the side window glass. This helps protect the occupants from head and facial injuries caused by impact with the window glass. See **Figure 85-13**.



Rear seat air bags fit into the rear cushion of the front seats. They inflate to protect the passengers in the rear seat from injury during a frontal collision. Although not very common, they can be found in a few luxury cars.

Inflatable seat belts use small air bags located in the shoulder harness straps. During a frontal impact, the air bag module can fire a small gas charge to inflate the air bag, increasing the surface area of the shoulder harness. See **Figure 85-14**. This causes the harness to more effectively hold the occupant in the

Goodheart-Willcox Publisher

Figure 85-11. Driver's-side and passenger-side air bags will normally deploy if impact is within 30° of a vehicle's centerline. Impacts on doors or sides may fire the side-impact air bags independently of frontal air bags.

Volvo

Figure 85-12. Side-impact air bags normally use their own sensors to detect side-impact forces. They only deploy when the impact force would tend to throw the body sideways and into the door.

Volvo

Figure 85-13. Note how side curtain air bags protect the head and face from being cut by side glass during a side impact from another vehicle. Side air bags and curtains also protect against neck lacerations caused by the shoulder harness during a severe side impact.

Ford

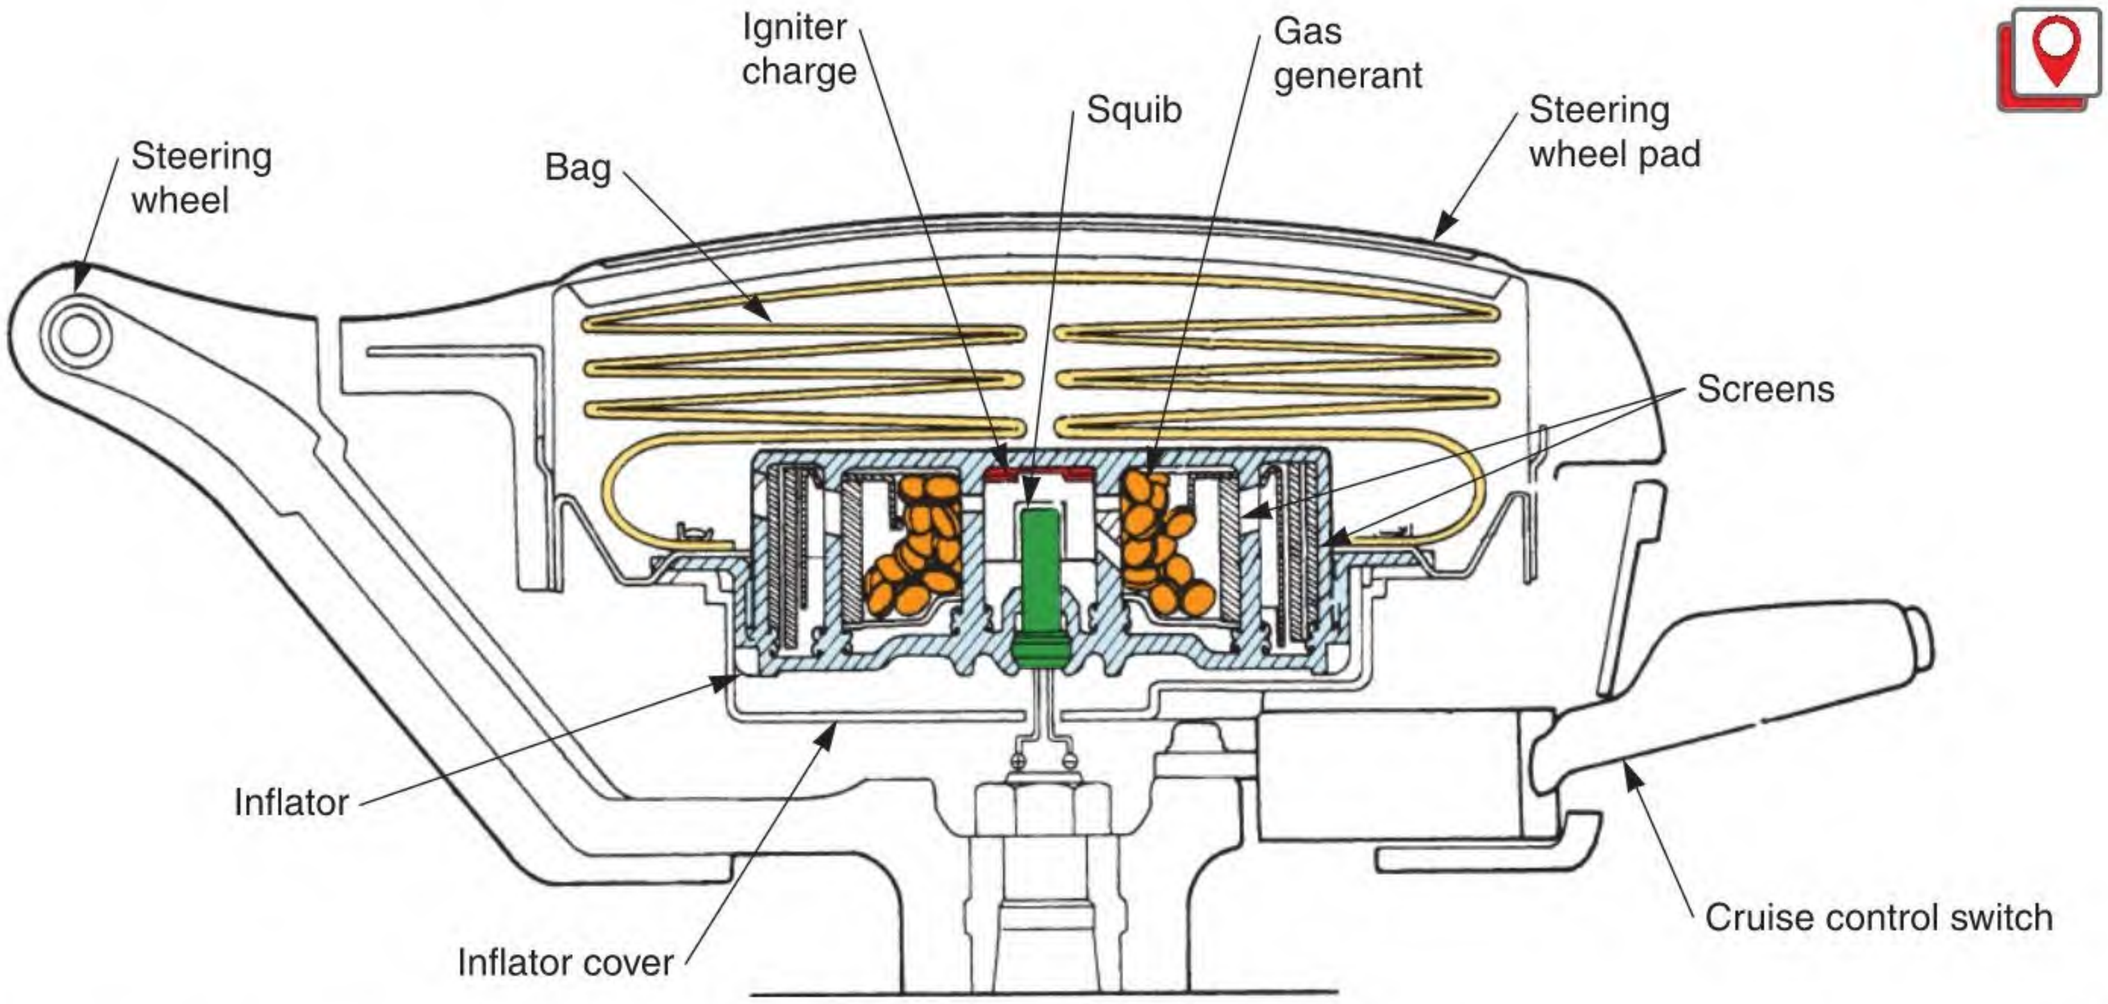
Figure 85-14. Inflatable seat belts use small air bags located in the shoulder harness straps to more effectively hold the occupant in the seat.

seat. It also spreads crash forces over a larger area, preventing the nylon shoulder harness strap from injuring the occupant's shoulder and chest.

Air Bag Module

The ***air bag module*** consists of a nylon bag and an igniter-inflator unit enclosed in a metal and plastic housing. The driver's-side air bag module is mounted in the center of the steering wheel. The passenger-side air bag module is mounted under a small door formed in the right side of the dash pad. Look at **Figure 85-15**.

The ***air bag*** itself is a strong, reinforced nylon sack attached to the metal frame of the module. It is tightly folded for storage in the steering wheel pad, the dash, the door panel, or the side of the seat. ***Air bag vent holes*** allow for rapid deflation of the air bag after deployment. These small holes are formed around the outer edge or back of the bag.



The ***air bag igniter*** generates a small electric arc when an electrical signal is sent to it from the air bag controller. The arc forms across two small pins in the igniter and fires an igniter charge. This flash of the igniter charge causes the gas-generating pellets to burn, generating a huge volume of expanding gas. See **Figure 85-16**.

Breed Automotive Corporation

Figure 85-15. This cutaway shows the inside of an air bag module. The flexible fabric air bag is folded neatly under the steering wheel cover. The air bag igniter generates a small electric arc across two metal pins when an electrical signal is sent to the igniter from the controller. The arc fires an igniter charge, causing the gas-generating pellets to burn. The burning pellets generate a rapidly expanding gas that inflates the air bag.

Copyright Goodheart-Willcox Co., Inc.

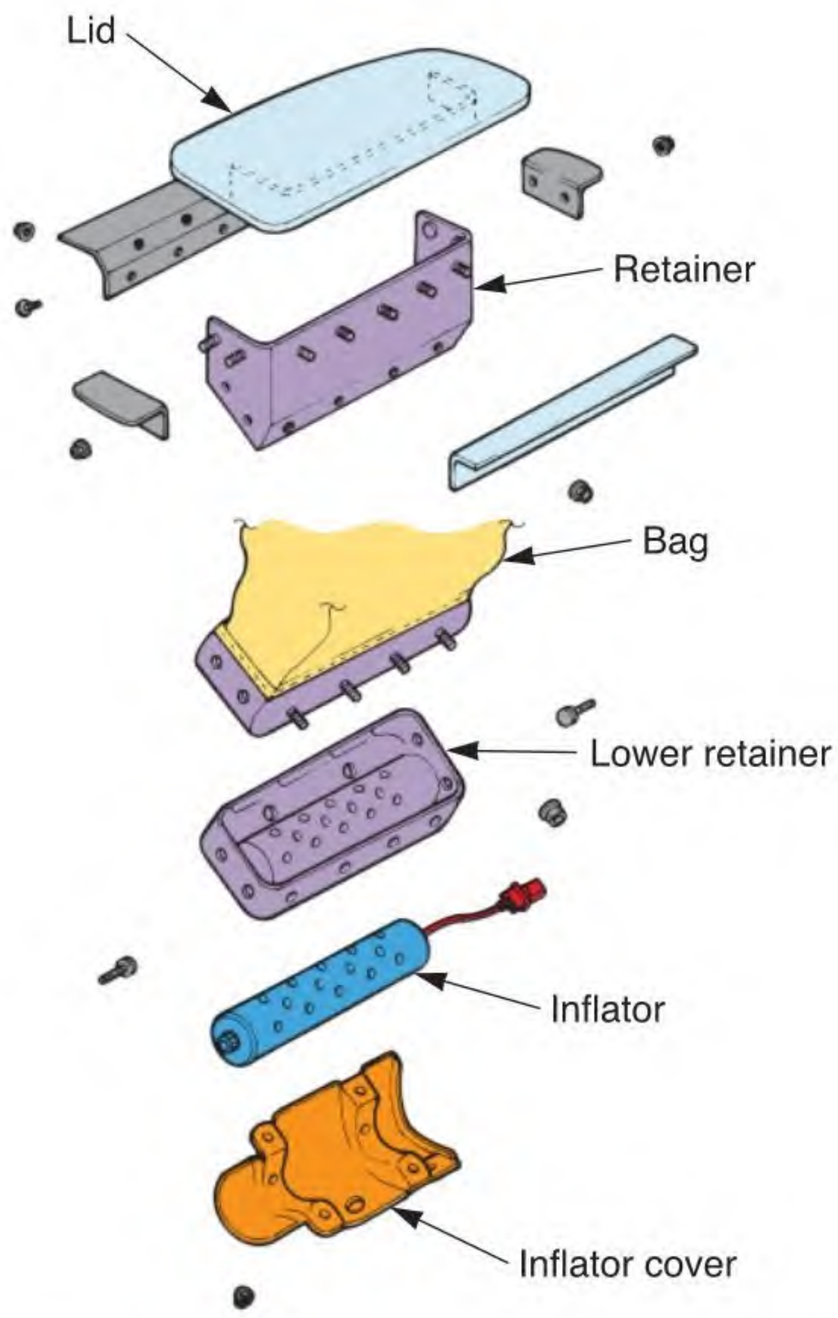
Toyota

Figure 85-16. This illustration shows the details of a common air bag module. Study the part names and locations carefully.

The air bag's ***propellant charge***, or expanding gas, is usually produced by the burning of sodium azide pellets in the air bag module. The burning pellets form nitrogen gas, which inflates the air bag.

The large volume of nitrogen gas can inflate the air bag in a fraction of a second. This forces the steering wheel cover to split open, and the air bag shoots out at about 200 miles per hour (320 kilometers per hour). This is fast enough to cushion the forward thrust of the human body as it flies forward after the collision. The air bags also protect the driver's and passengers' heads from flying objects resulting from the accident.

Immediately after the air bag is inflated, the gas is vented out the small holes on the sides or rear of the bag. This prevents the occupants from being pinned in their seats. It also allows the driver to see out of the windshield right after deployment. Study the stages of air bag deployment shown in **Figure 85-17**.



Passenger-side and side-impact air bags are very similar in design. The passenger-side air bag is much larger than a side-impact bag and, therefore, requires more gas for proper inflation. An exploded view of a passenger-side air bag is shown in **Figure 85-18**.

Chrysler

Figure 85-17. Note the stages of air bag deployment. A—During initial deployment, the air bag expands and tears through the plastic cover on the steering wheel pad. B—An air bag inflates at a tremendous speed because it must be fully inflated before the driver hits the bag when thrown forward by the collision force. C—Once the air bag is fully inflated, vent holes allow the bag to slowly deflate so the driver can get out of the vehicle after the accident.

Copyright Goodheart-Willcox Co., Inc.

Honda

Figure 85-18. Exploded view shows the major parts of a passenger-side air bag, which fits in the right side of the dash.

Hybrid Air Bags

A ***hybrid air bag*** uses two methods to inflate the air bag: a small explosive charge and a pressurized gas cartridge. The pressurized gas is much safer and easier to control than the hot nitrogen gas produced by burning sodium azide pellets. The small, metal ***gas cartridge*** contains inert argon gas pressurized to 3000 psi (20,700 kPa).

When the air bag controller sends current to a thin wire heating element, the element heats up and fires a small amount of pyrotechnic material (rapidly burning substance) that forces a "plastic bullet" through the end of the gas cartridge. The cool, pressurized gas then flows out to inflate the air bag.

A hybrid air bag is designed to help prevent minor skin burns that can result from the hot nitrogen gas used to inflate a conventional air bag. Refer to **Figure 85-19**.

Air Bag Sensors

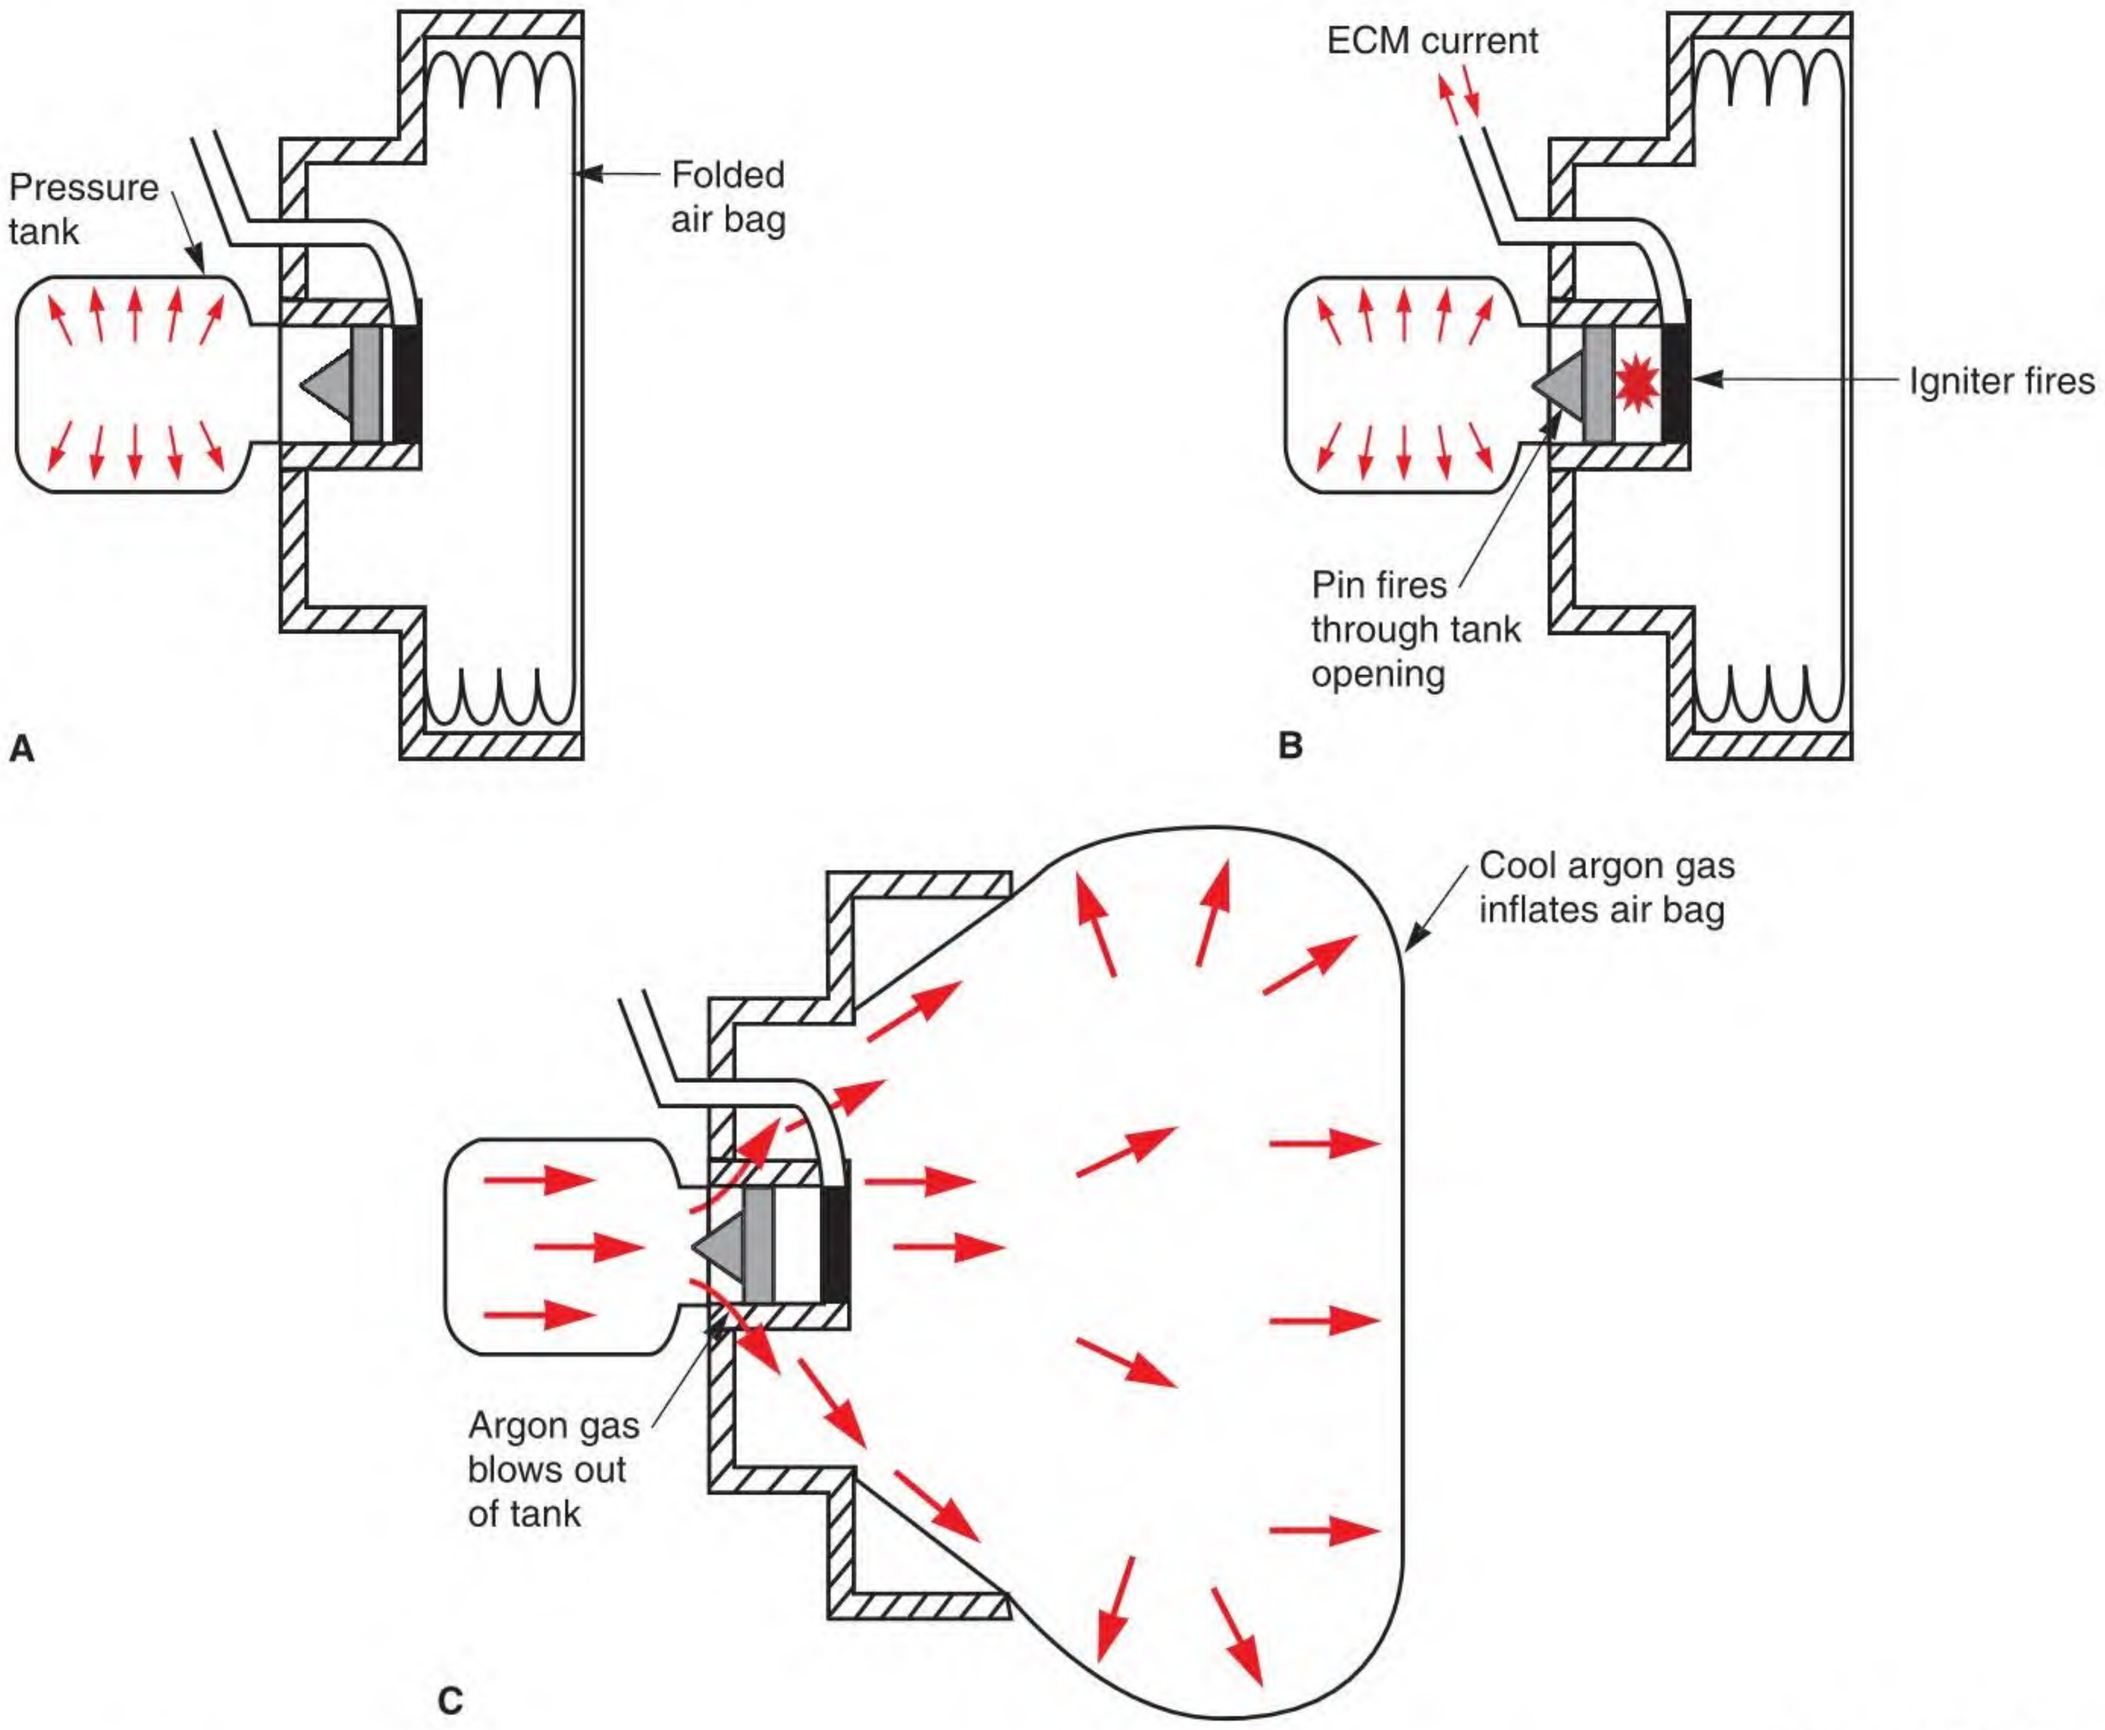
Air bag sensors detect a collision by measuring vehicle deceleration during a collision. They are inertia sensors that detect a rapid change in speed or velocity. One or more sensors are commonly incorporated into air bag systems. The trend is to use fewer sensors than in the past.

Impact sensors are mounted in the front and, in some cases, on the sides of a vehicle to detect a collision. Front impact sensors are often located in the engine compartment, on or near the radiator support. See **Figure 85-20**. Side impact sensors are mounted in the doors or in the B-pillars (pillars behind the front doors).

A ***safing sensor***, or ***arming sensor***, is a backup sensor designed to ensure that the vehicle is actually in a collision. It provides a fail-safe system to prevent accidental bag deployment. For the inflation of the air bags, the safing sensor and at least one impact sensor must be closed.

Magnet-and-Ball Sensors

A ***magnet-and-ball sensor*** is used in some air bag systems as the impact sensor. A small permanent magnet is used to hold a steel ball away from the electrical contacts in the sensor. During a severe collision, the rapid deceleration throws the steel ball forward, overcoming the force of the magnet. The ball rolls forward and strikes electrical contacts. This closes the sensor circuit to signal the controller of a possible collision requiring air bag deployment. See **Figure 85-21**.



Coil Spring Sensors

A ***coil spring sensor*** uses a small metal weight attached to a metal coil spring. During a severe frontal impact, the weight is thrown forward with enough force to overcome spring tension. The weight touches the sensor contacts and closes the circuit to the air bag controller.

Seat Cushion Sensors

Seat cushion sensors detect the weight of a person sitting in the passenger seat. If no one is sitting in the passenger seat, the air bag system may not deploy the passenger-side air bag. This saves the considerable cost of replacing an air bag without it protecting someone. If a small child is in the passenger seat, the air bag will inflate with less force to protect the child from injury. See **Figure 85-22**.

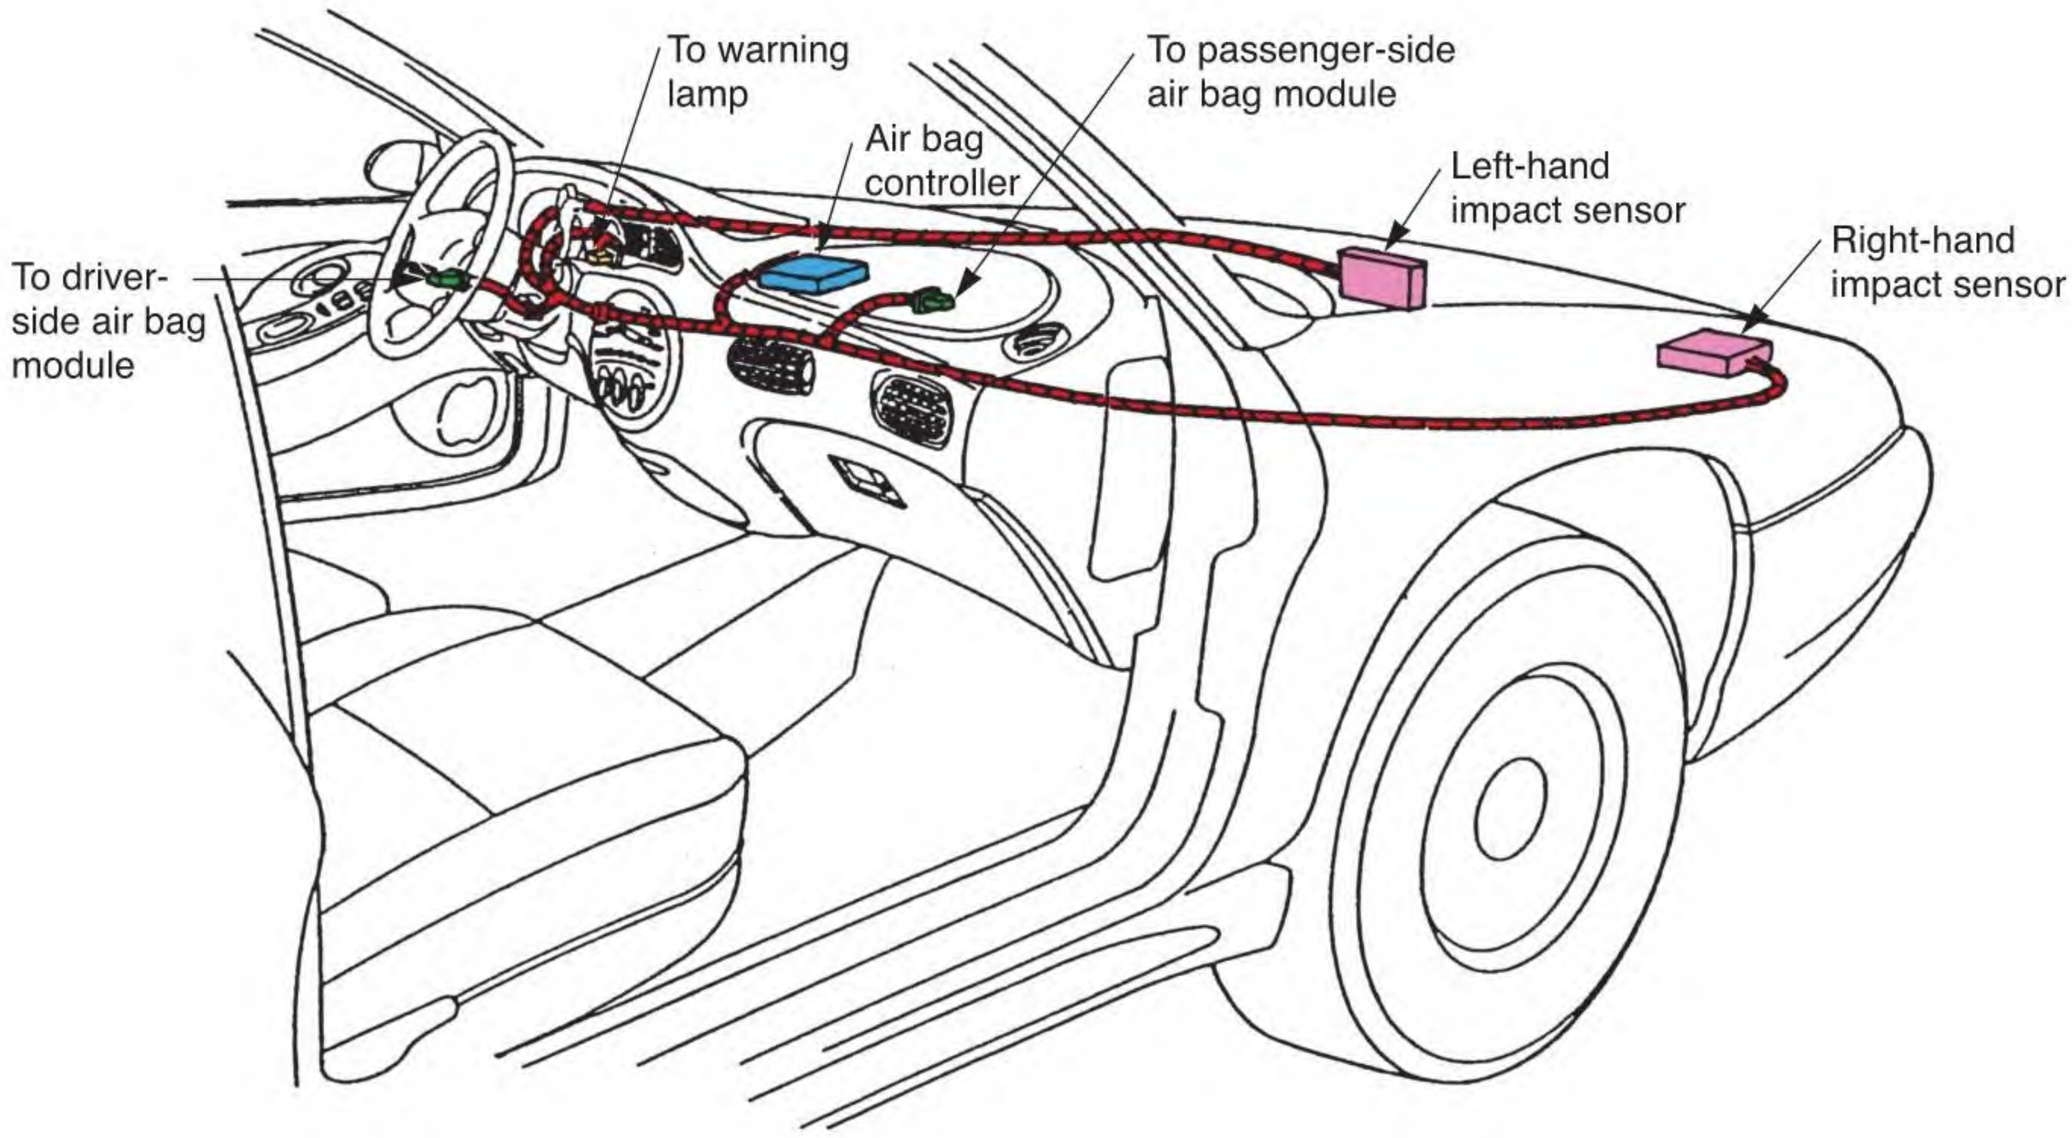
Goodheart-Willcox Publisher

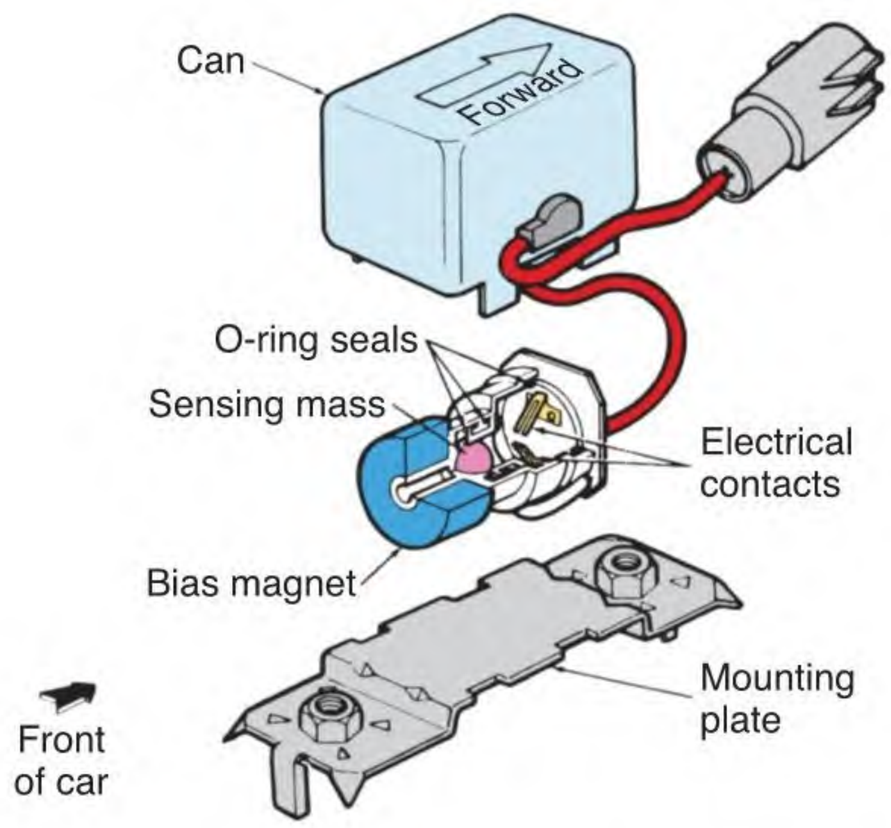
Figure 85-19. A hybrid air bag uses both pyrotechnic material and a container of pressurized gas to cause air bag inflation. A—The metal tank is filled with argon gas. The igniter is mounted on one end of the tank. The air bag is folded inside the steering wheel cover. B—The controller detects a collision and sends current to the igniter. The igniter fires, forcing a plastic projectile through the end of the tank. C—A hole formed in the end of the tank allows cool argon gas to blow out and inflate the air bag.



Accelerometer Sensors

Many late-model vehicles are equipped with one central ***accelerometer*** (inertia sensor) instead of separate impact and safing sensors. The accelerometer measures changes in motion or deceleration and is sometimes mounted in the air bag controller. Some accelerometers contain a thin wafer of semiconductor material that is deflected and warped by rapid deceleration. The bending of the semiconductor produces a piezo-electric, or pressure-generated, electrical signal that fires the air bag.

Decibel Impact Sensors



A ***decibel impact sensor*** can measure the amount of sound produced by a major collision. A minor impact will produce less sound and a weaker sensor signal than a major impact. This allows the air bag ECM to deploy the air bags more slowly in a minor accident. In a major, potentially deadly impact, the ECM can use decibel sensor signals to deploy the air bags at maximum speed to better protect people from injury. See **Figure 85-23**.

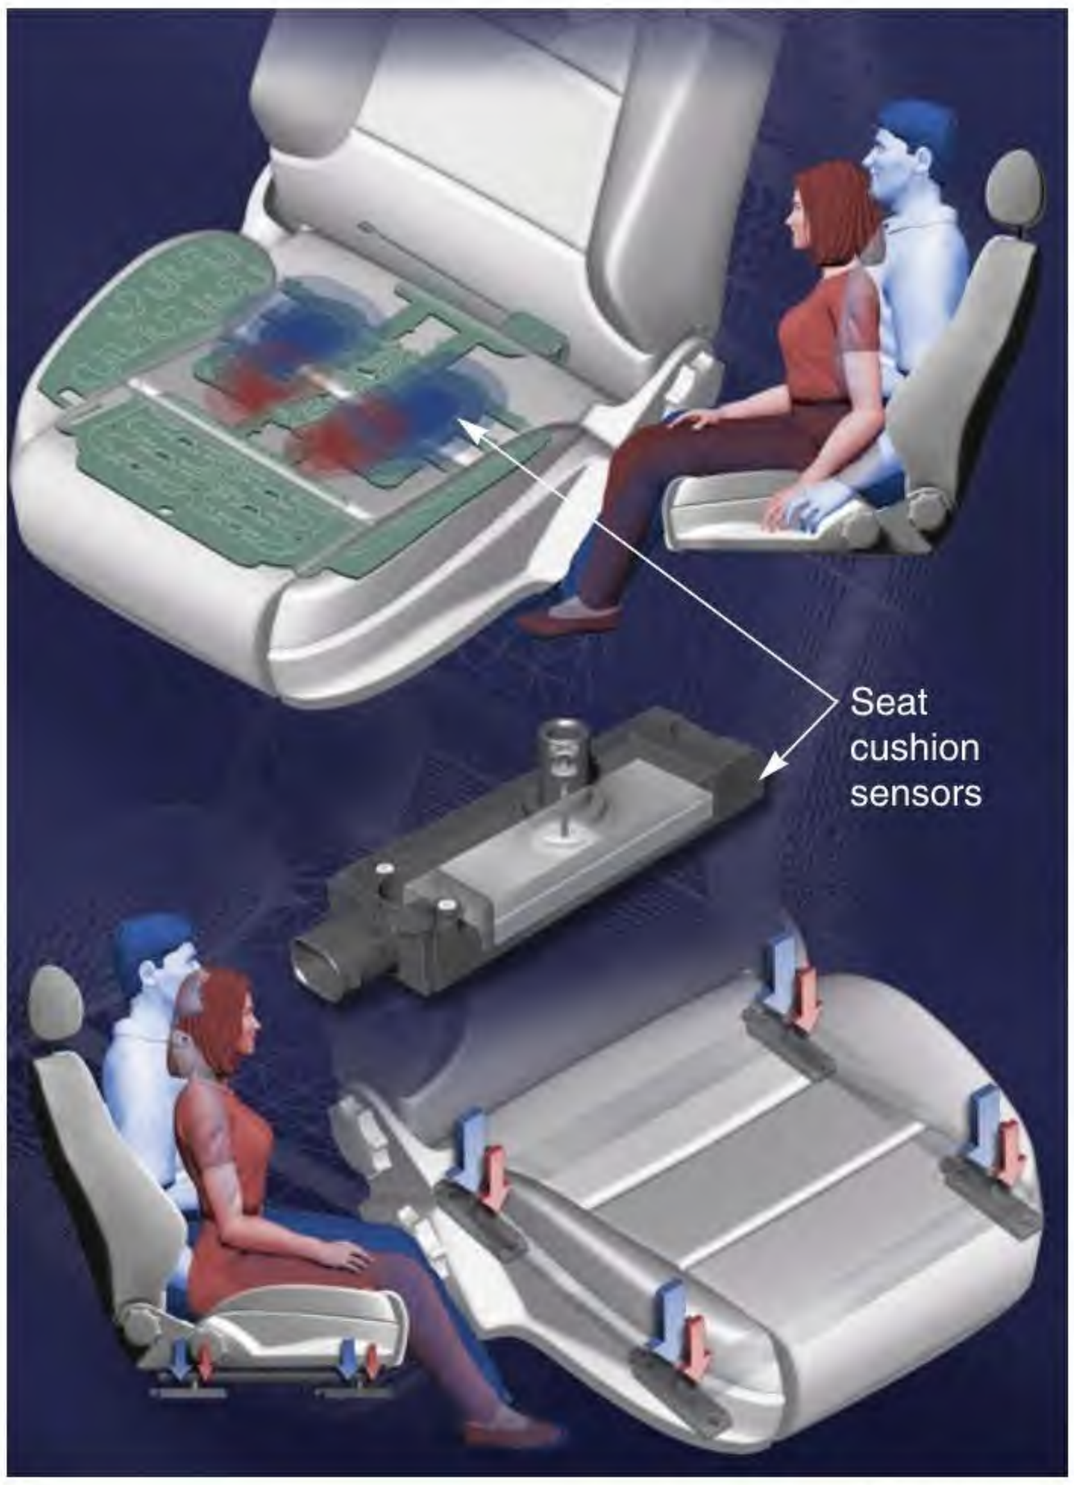
Copyright Goodheart-Willcox Co., Inc.

Ford

Figure 85-20. Typical location of the air bag impact sensors. They are often mounted near the radiator support.

Ford

Figure 85-21. An air bag system sensor closes when exposed to rapid deceleration forces. This sensor uses a magnet to hold a steel ball. If impact is great enough, the steel ball is thrown away from the magnet and into the two metal contacts. This closes the circuit and signals the controller that the vehicle is in a collision. Note that contacts can be plated with pure gold to ensure a good electrical contact after years of service.



Air Bag Controller

The ***air bag controller***, or ***air bag control ECM***, uses inputs from the impact and safing sensors to determine if air bag deployment is needed. If at least one impact sensor and the safing sensor are closed, the controller sends a high current pulse to the air bag module. The pulse produces a small electric arc in the air bag module, igniting the pyrotechnic material to produce gas expansion and bag inflation, **Figure 85-24**.

The air bag controller also generates trouble codes and energizes a warning lamp if it detects something wrong with the system. Refer to **Figure 85-25**.

A ***smart restraint system*** uses additional inputs to affect the operation of the air bags. It uses conventional impact sensor inputs, as well as data from the seat sensors, side door impact sensors, yaw sensors, wheel speed sensors, seat belt sensors, and even collision-predicting sensors. This allows the smart system to adjust the speed and pressure applied to the air bags to better protect the vehicle's occupants from injury.

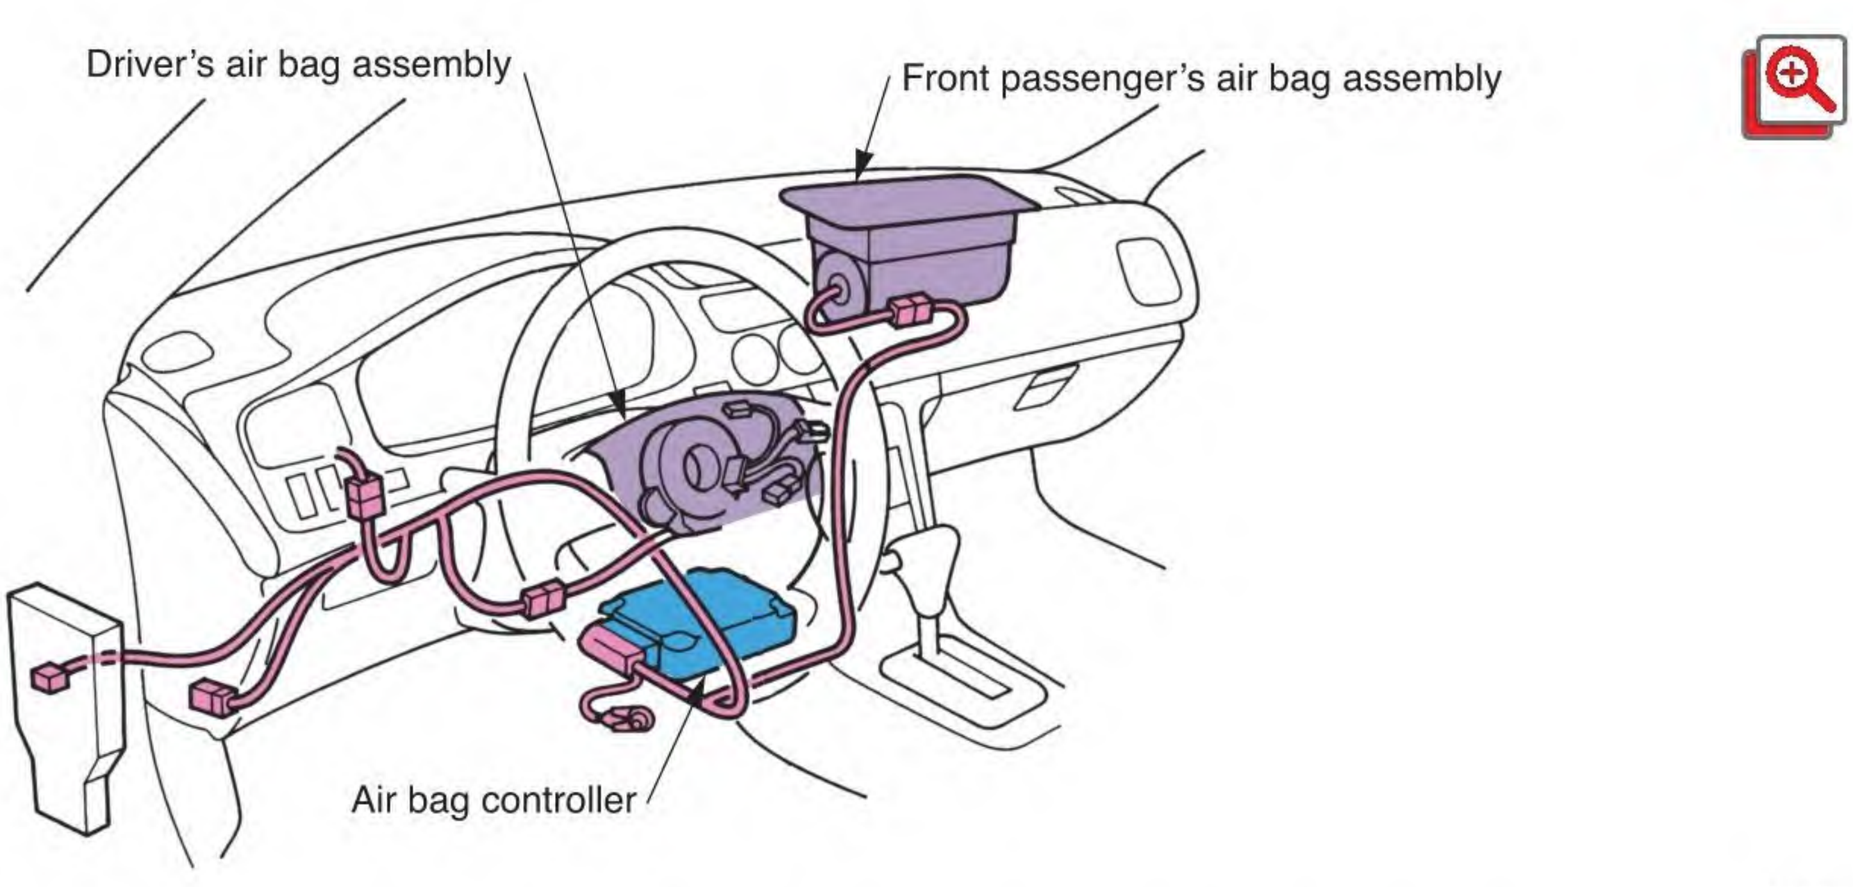
Mercedes-Benz

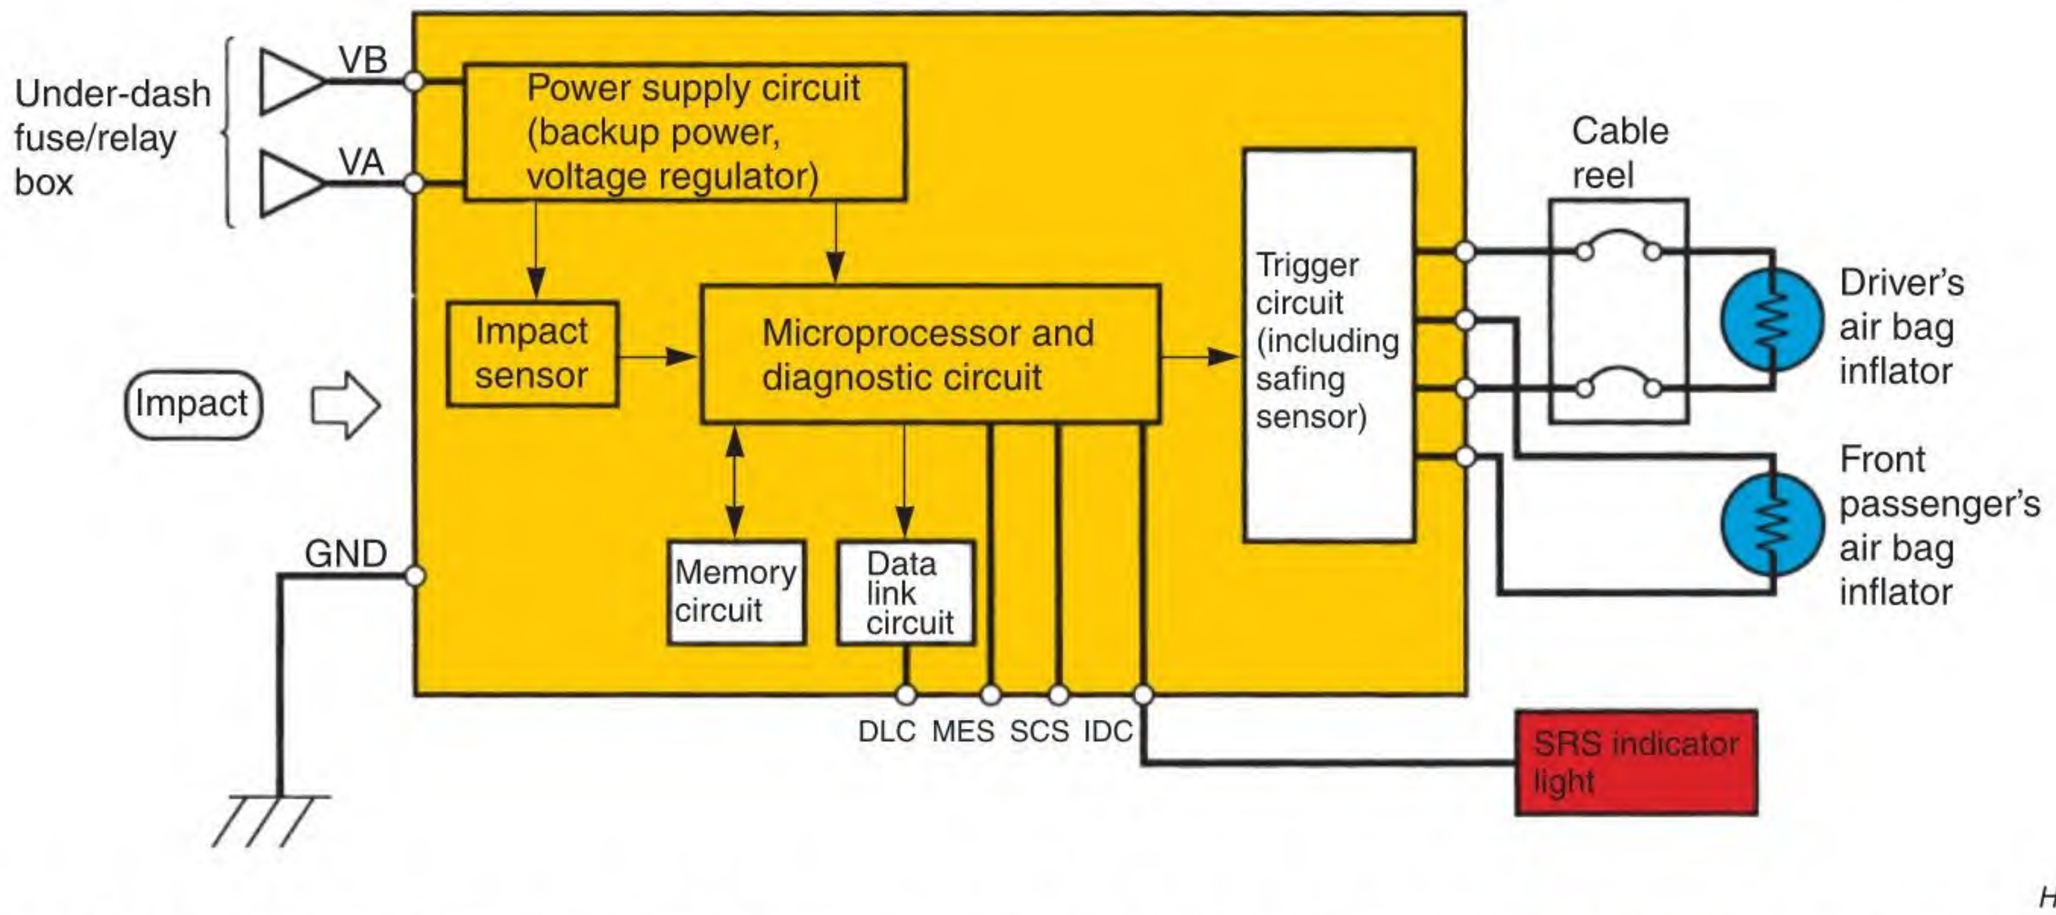
Figure 85-22. Signals from seat cushion sensors can be used by the air bag controller to control the speed and force of air bag deployment.



Siemens

Figure 85-23. This air bag system uses a decibel impact sensor that measures the severity of the collision. The louder the crash, the stronger the signal the impact sensor sends to the air bag controller. This allows the controller to inflate the air bag slowly in a minor collision or more quickly in a major collision.

Event Data Recorder



An ***event data recorder***, or flight recorder, monitors and records vehicle operating conditions and stores them in memory. Dealerships and insurance companies can unlock and retrieve this data to determine if a driver was speeding or driving erratically right before a major auto accident. On most new passenger vehicles, the event data recorder is built into the air bag controller or the engine control module (ECM).

Honda

Honda

Figure 85-25. This diagram shows how the air bag controller operates. Note that the controller has self-diagnostic capabilities and will generate a trouble code if any component in the system has abnormal voltage, resistance, or current levels.

Industry Trend

The technology found in typical late-model vehicles helps to prevent thousands of highway deaths each year. Many high-speed accidents, which were often fatal in yesterday's lower-tech cars, now result in only minor injuries. This improved safety record is primarily due to the superior structural body/frame designs and advanced restraint systems found in today's vehicles. Air bags, front and rear crush zones, stronger pillars, and reinforced passenger compartments have all contributed to improved vehicle safety.

Summary

- Crush zones, located at the front and rear of the body-frame assembly, are designed to collapse during a severe impact.
- Crash tests are used by the auto manufacturer to measure how well the body-frame structure will protect the driver and passengers in a major collision.
- Crash test dummies are used to measure the forces acting upon the human body during a collision.
- Seat belts are strong nylon straps that hold people in their seats during a collision.
- A knee diverter is formed into the lower part of the dash to prevent the driver's and front passengers' knees from being injured on the metal frame of the dash.
- An air bag system automatically inflates a large nylon bag immediately after the start of a major collision.
- All late-model vehicles are equipped with dual air bags: a driver's-side air bag and a passenger-side air bag, which deploys from the right side of the dash.
- Side-impact air bags can be located in the door panels or on the outside edges of the front seats.

Copyright Goodheart-Willcox Co., Inc.

- The air bag module consists of a nylon bag and an igniter-inflator unit enclosed in a metal-plastic housing.
- A hybrid air bag uses a small explosive charge and a pressurized container of gas to inflate the air bag.
- Air bag sensors detect a collision by measuring vehicle deceleration.
- A safing sensor, or arming sensor, is a backup sensor designed to ensure that the vehicle is actually in a collision.
- A smart restraint system uses additional inputs to affect the operation of the air bag system.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

accelerometer
accidents
active restraint system
air bag
air bag control ECM
air bag controller
air bag igniter
air bag module
air bag sensors
air bag system
air bag vent holes
arming sensor
belt retractor

coil spring sensor
crash test dummies
crash tests
crush zones
decibel impact sensor
driver's-side air bag
event data recorder
gas cartridge
hybrid air bag
impact sensors
inflatable seat belts
knee bolster
knee diverter
lap belts
magnet-and-ball sensor
passenger-side air bag
passive restraint system
propellant charge
rear seat air bags
safing sensor
seat belt anchors
seat belt buckle
seat belt reminder system
seat belts
seat cushion sensors
shoulder belts
side curtain air bags
side-impact air bags
side-impact beams
smart restraint system
vehicle collisions

Activities

1. Visit a local salvage yard. Ask to inspect deployed air bags in wrecked vehicles. Write a report on the amount of damage to the vehicle.
2. Read service manual literature on air bags.
3. Visit the library and look up articles in periodicals on air bags. Give a presentation to the class about interesting facts found in these articles.

Review Questions

Answer the following questions using the information provided in this chapter.

1. A(n) _____ _____ helps hold the driver and passengers in their seats to prevent them from being injured during a collision.
2. What are *crush zones*?
3. The _____ takes the slack out of the seat belt, so it fits around the body snugly.
   (A) anchor
   (B) buckle
   (C) retractor
   (D) propellant
4. Name the major parts of an air bag system.
5. The largest air bag in a dual air bag system is the _____.
   (A) driver's-side air bag
   (B) passenger-side air bag
   (C) side-impact air bag
   (D) rear seat air bag
6. Describe the air bag module.
7. How fast can an air bag travel during deployment?
   (A) 100 mph (160 km/h).
   (B) 150 mph (240 km/h).
   (C) 200 mph (320 km/h).
   (D) 300 mph (480 km/h).
8. Explain the operation of a hybrid air bag system.
9. Air bag sensors detect a collision by measuring _____ of the vehicle during a collision.
10. The trend is to replace several air bag sensors with a central _____.

ASE-Type Questions

1. Technician A says manual seat belts are passive restraints. Technician B says air bags are active restraints. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following tests is used to analyze how well the vehicle structure protects the driver and passengers?
   (A) Beam test.
   (B) Crush zone test.
   (C) Crash test.
   (D) Dummy test.
3. Which of the following parts helps prevent leg injuries?
   (A) Knee diverter.
   (B) Pedal cushions.
   (C) Tilt wheel.
   (D) Padded dash.
4. With most systems, how many sensors must be energized before the air bag will deploy?
   (A) One.
   (B) Two.
   (C) Three.
   (D) Four.
5. Technician A says that the driver's-side air bag may not deploy if the direction of impact is more than about 30° from the vehicle's centerline. Technician B says that side air bags may not deploy during a frontal impact. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. All of the following are found in motor vehicles, *except:*
   (A) rear seat air bags.
   (B) knee air bags.
   (C) side-impact air bags.
   (D) side curtain air bags.
7. Technician A says that the air bag controller is usually located on the vehicle's steering wheel. Technician B says that the driver's-side air bag module is located in the steering wheel. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says that hybrid air bags use a small explosive charge to inflate the air bag. Technician B says hybrid air bags use a pressurized gas cartridge. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Which of the following is *not* an air bag sensor?
   (A) Arming sensor.
   (B) Safing sensor.
   (C) Accelerometer sensor.
   (D) Proximity sensor.
10. Front impact air bag sensors are usually located in the:
    (A) engine compartment.
    (B) passenger compartment.
    (C) doors.
    (D) trunk.

Chapter 86
Restraint System Service

After studying this chapter, you will be able to:

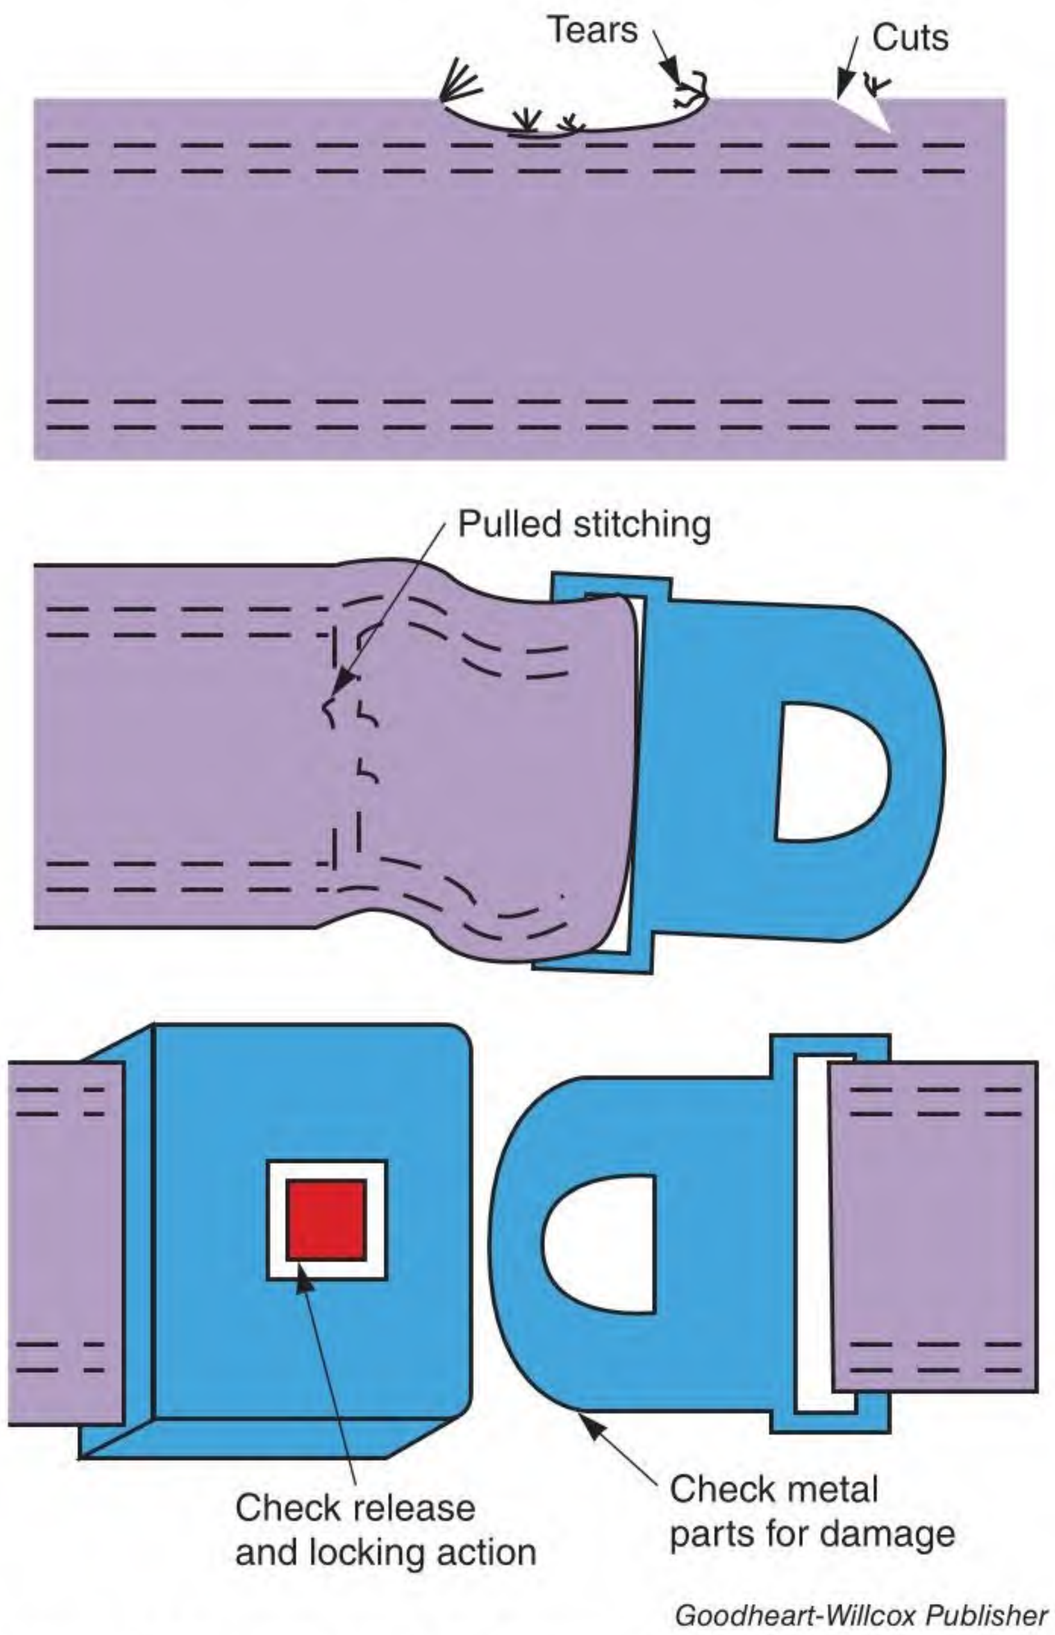
- Explain how to inspect and repair seat belts and their retracting mechanisms.
- Use a scan tool to diagnose and repair restraint systems.
- Describe safety rules for working with air bags.
- Safely disconnect 12-volt and, if necessary, HV battery power from restraint system circuit before working on the system.
- Summarize the procedure for air bag replacement and disposal.
- Explain how to replace air bag sensors.
- Correctly answer ASE certification test questions about the diagnosis and repair of restraint systems.

The proper operation of seat belts and air bags is critical to the safety of the driver and his or her passengers. If you make the slightest mistake when servicing these important safety devices, you will endanger the people who trust your work.

An air bag also has the potential to cause serious injury to you and others in the shop if handled improperly. Air bags "pack a powerful punch" when deployed, expanding outward at a speed up to 200 mph (320 km/h). This chapter will summarize the most important procedures for correctly servicing air bags and seat belts. Study it carefully.

Warning

Warn customers of the danger of placing children in front seats of vehicles equipped with dual air bags. Air bags have been blamed for the deaths of several small children. Children should be placed in the rear seats of the vehicles. They should be buckled into an approved child seat until they are tall enough to be restrained properly by a seat belt.



Seat Belt Service

Seat belts can be damaged by the force of a collision and their cloth fabric can deteriorate over time. Therefore, seat belt mechanisms and the belts themselves should be inspected after an accident or prolonged use, **Figure 86-1**.

Seat Belt Inspection

To inspect a seat belt for damage, pull the belt all the way out of its retractor. Inspect the belt fabric, or webbing, for cuts, pulled threads, broken thread loops, color fading, and fabric deterioration. Look for twisted

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 86-1. Inspect seat belt assemblies for these types of problems.

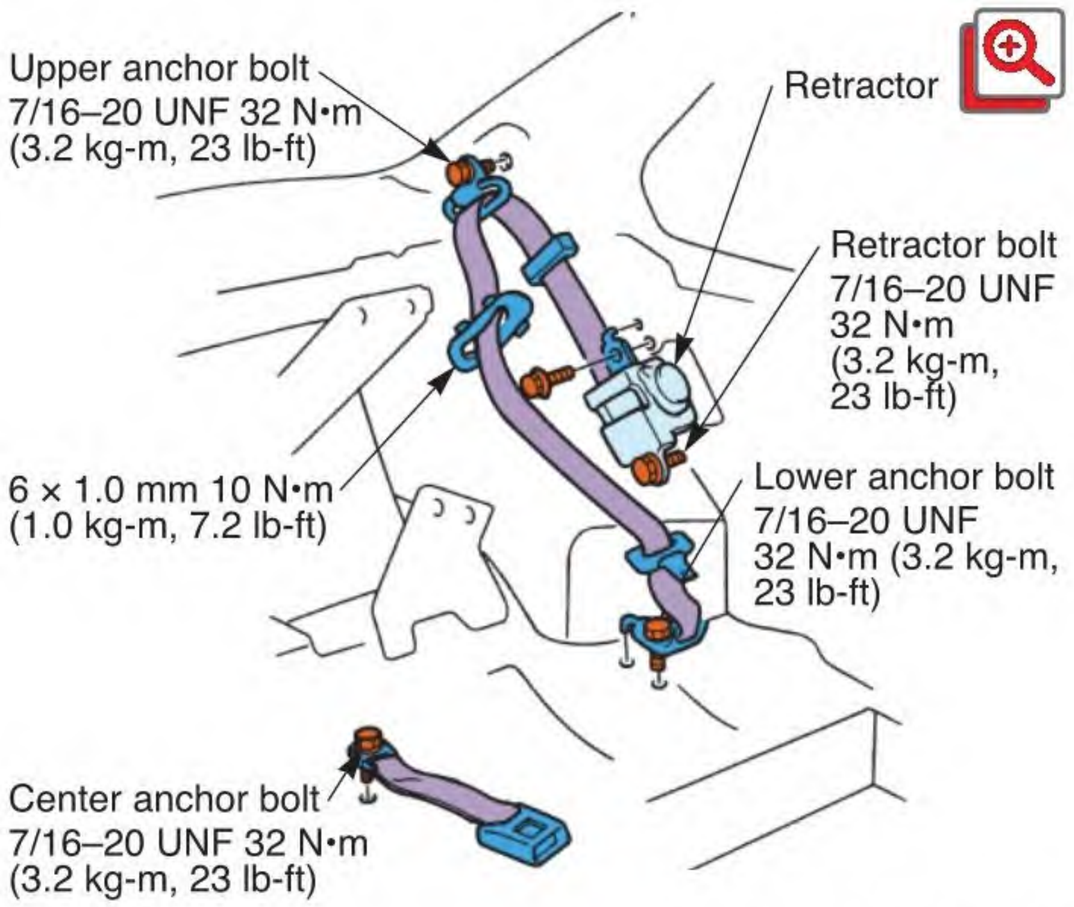
webbing, which could make the belt stick in its retractor or guide plates. If necessary, untwist the belt so it moves freely in and out of the retractor and guides.

Fit the two ends of the seat belt buckle together. Listen for a solid click. Then, try to pull the buckle apart by pulling sharply on the belt. The two ends must not disengage. Make sure the belt buckle will release with normal finger pressure. Inspect the belt anchors for problems (bent, cracked, loose, etc.).

Replace the seat belt assembly if problems are found. Repeat this procedure on all other seat belts.

Seat Belt Service

Seat belt service generally involves removing the damaged belt and replacing it with a new seat belt assembly. When replacing a seat belt, remember the following precautions:



- Sharp edges on sheet metal body parts and on tools can damage seat belts. Even small cuts can weaken the belt webbing, causing it to snap during a collision.
- Never attempt to straighten any portion of the belt buckle, latch plate, or anchor plate. If bent, the components should be replaced.
- Inspect seat belt anchors for bending, cracking, or looseness. When replacing anchors, use the correct grade case-hardened bolts. If common low-strength steel bolts are used, they could break during an accident, allowing the occupant to be ejected from the seat.
- Use a torque wrench to tighten all seat belt anchor bolts to factory specifications. See **Figure 86-2**.

Belt Retractor Service

Seat belts commonly use one of two belt retractor mechanisms: a centrifugal retractor or a pendulum retractor.

A ***centrifugal belt retractor*** uses centrifugal force to keep the belt from extending. If you pull on the belt hard enough, the rapid centrifugal force engages the locking mechanism so the belt holds the driver or passenger in the seat.

To check the action of this type belt, simply pull out on the belt quickly. It should lock, and you should not be able to extend the belt further. Pulling slowly should allow free lengthening of the belt out of the retractor.

Goodheart-Willcox Publisher

Figure 86-2. Always tighten seat belt anchor bolts and retractor bolts to specifications.

Copyright Goodheart-Willcox Co., Inc.

A ***pendulum belt retractor*** uses the inertia of a small hinged metal weight to engage the seat belt's locking mechanism during vehicle deceleration. When the vehicle brakes or stops quickly, a small pendulum in the retractor is thrown forward, causing the belt locking mechanism to engage.

To test this type of belt, find an open road or an empty parking lot. Drive the vehicle at approximately 10 mph and then hit the brakes hard. The belt should lock up as the vehicle comes to a stop. If the belt still does not lock, the retractor should be replaced.

Tech Tip

Most manufacturers recommend that certain seat belt system parts be replaced after a major collision. For example, many manufacturers recommend replacing seat belt retractors and inertia sensors after a collision, as these components can be mechanically damaged by the rapid deceleration.

Air Bag System Service

Air bag service is needed after deployment or when the dash malfunction light indicates a problem. For your safety and the safety of the people relying on the air bags, proper repair methods must be followed.

Warning

Remember to be cautious to prevent accidental air bag deployment when working. An air bag has enough force to break bones and cause serious injury. Always disconnect the battery before beginning work. Keep your head and arms to one side of the air bag when testing, removing, and installing a new module. Never place your head close to the steering wheel or reach through the wheel spokes during service.

Scanning an Air Bag System

If the air bag indicator light glows and the bag is not deployed, use a scan tool to analyze the system. Connect the scan tool to the vehicle's diagnostic connector and read any trouble codes. These codes will tell you where circuit problems might exist for further testing.

Tech Tip

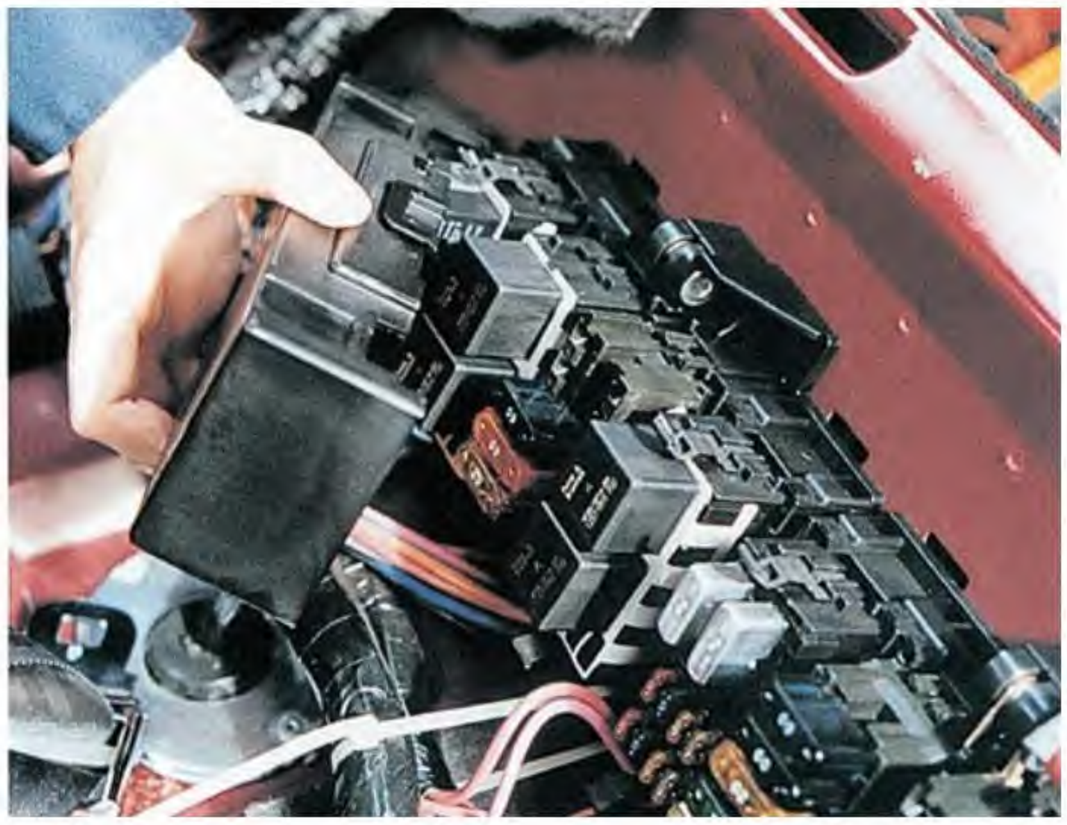
Warn customers of the danger of placing items such as jewelry, keys, cell phones, etc., on their dash or hanging objects from their rear view mirrors. These items pose a safety risk to a vehicle's occupants.

Even in minor accidents, people have been seriously injured when the air bags deploy and propel items in their path directly at the vehicle's occupants. In one case, a car's passenger had just set a cell phone on the dash when the driver rear-ended another vehicle at only 30 mph. The passenger was seriously injured when the air bag deployed and propelled the cell phone at her head, causing face and neck lacerations Remember that anything hanging in front of or placed in the path of an air bag can become a potentially deadly projectile. Make sure all items are removed from the dash before you repair a vehicle.

Air Bag Module Service

The air bag module must be serviced when it is deployed, defective, or damaged. You must often remove or disable the module when working on the steering column. It is important that specific procedures be followed to ensure personal safety and proper air bag operation.

Disarming an Air Bag



Before servicing a vehicle equipped with an air bag, the system must be disarmed. To disarm an air bag system, all sources of electricity for the igniter must be disconnected from the air bag module. This would include disconnecting the 12-volt battery and, on hybrid vehicles, disconnecting the HV battery by removing the high-voltage disconnect. Procedures vary with the vehicle make and model.

Manufacturers may also specify the removal of a specific system fuse or disconnection of the controller. Always refer to the service manual for exact procedures for disarming the system. This will help prevent electrical system damage and accidental deployment, **Figure 86-3**.

Warning

Air bag systems are often equipped with an ***energy reserve module,*** which can deploy the air bag after a power failure. The energy reserve module must be disconnected or allowed to discharge for up to 30 minutes after disconnecting the battery. Refer to the service manual for details.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 86-3. Follow service manual instructions to disable the air bag system. You may have to follow a specific sequence. For example, you may be instructed to pull a fuse, disconnect the module, and then disconnect the battery.

Manual Air Bag Deployment

Manual air bag deployment is done by connecting a voltage source to the air bag module wires to "fire" the air bag. Manual deployment is needed if the vehicle is to be scrapped at a salvage yard (total loss from accident) or if the air bag module is damaged or defective. Used air bags are not recommended for reuse in another vehicle for safety reasons.

Warning

Never deploy a passenger-side air bag unless the vehicle is being scrapped for salvage. Passenger-side air bag deployment can break the windshield and damage dash components.

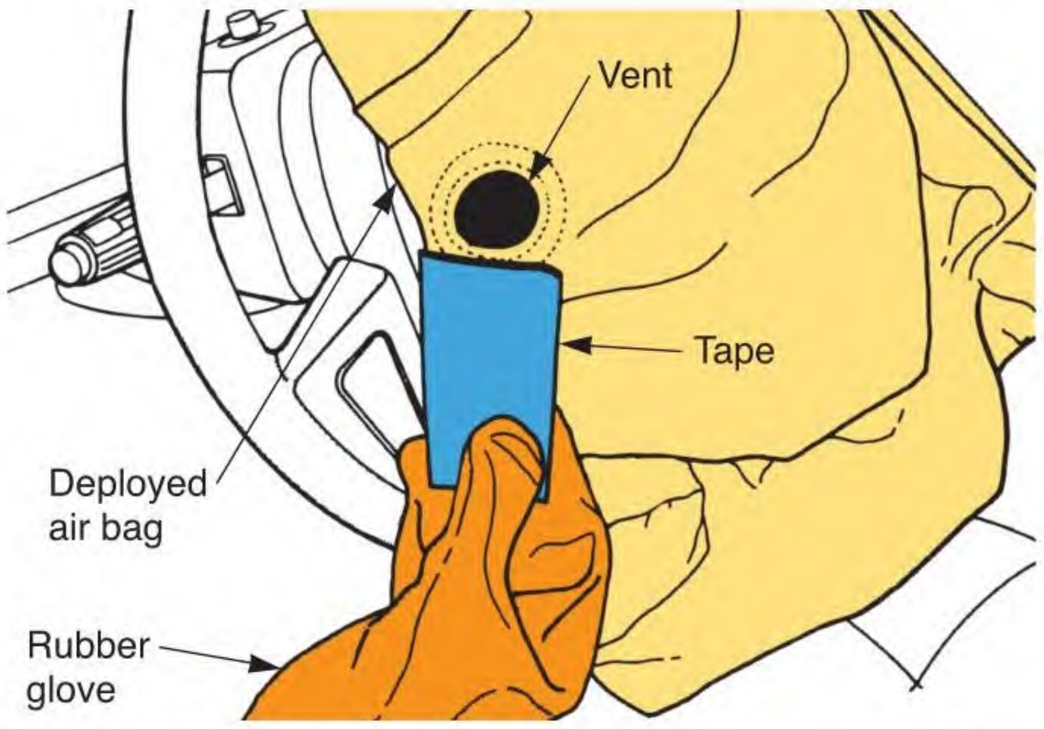
Service Procedure

To manually deploy an air bag:

1. Disconnect the wires between the controller and air bag. Most manufacturers recommend that the air bag remain mounted securely in the vehicle.
2. Connect long jumper wires to the wires going into the air bag igniter. The jumper wires must be long enough to reach to the rear of the vehicle. Wrap the other ends of the jumper wires together to short them and prevent accidental deployment.
3. With everyone clear of the area, connect the other ends of the jumper wires to an automotive battery. The air bag should deploy with a loud pop, and the deployed bag should be visible.
4. During deployment, the air bag becomes extremely hot and can cause serious burns. Wait at least thirty minutes before touching the deployed air bag assembly.

Warning

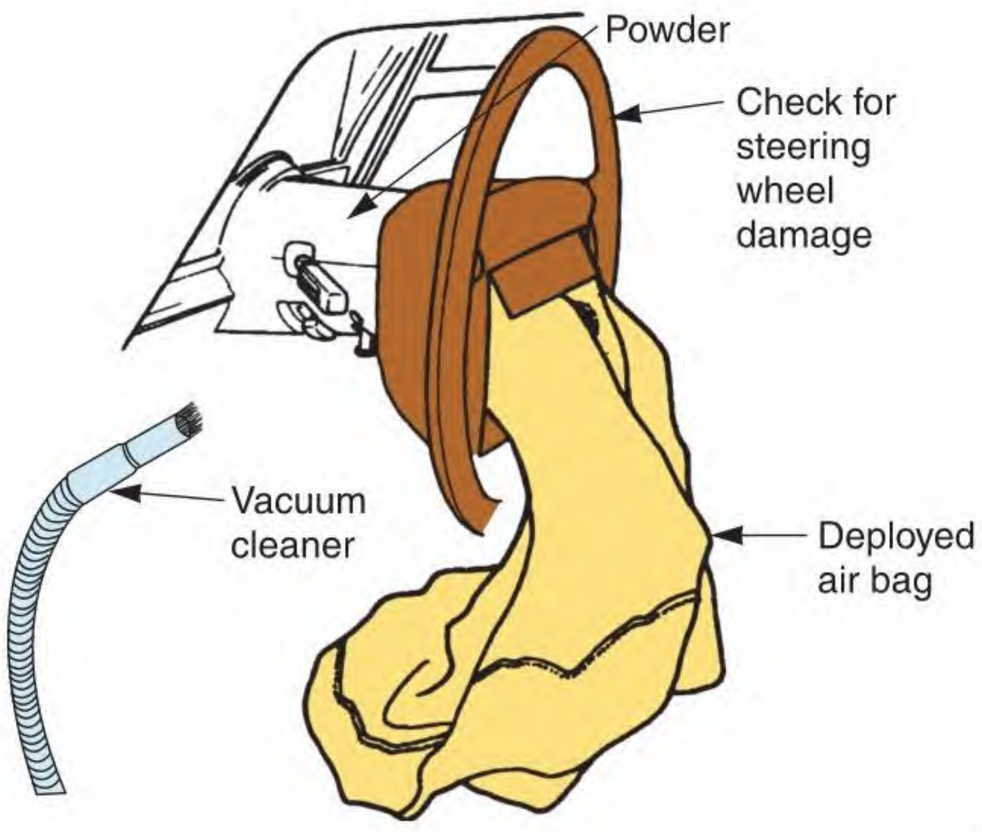
Never connect the jumper wires to the battery before connecting them to the air bag module. This will make the bag deploy as soon as the jumper wires are connected to the module, usually resulting in serious injury to the technician.



Air Bag Disposal/Recycling

Service Procedure

After deployment, the air bag must be removed and disposed of properly. Follow all disposal information to avoid breaking federal law.



1. Wear rubber or plastic gloves, a respirator, and safety glasses when handling a deployed air bag.
2. ***Air bag powder***, usually sodium hydroxide, is a skin, eye, and throat irritant that may blow out of the air bag upon deployment. Place pieces of tape over the vent holes in the air bag. This will help keep residual powder from leaking out the vents during bag removal, **Figure 86-4**.
3. To remove the deployed air bag, remove the screws from the rear of the steering wheel. Lift the module out and disconnect the wires.
4. Use a shop vacuum to clean up any air bag powder in the passenger compartment. The air bag powder can be an eye and skin irritant. Vacuum the dash, vents, seats, carpet, and other surfaces contaminated with this powder. Refer to **Figure 86-5**.

Copyright Goodheart-Willcox Co., Inc.

Chrysler

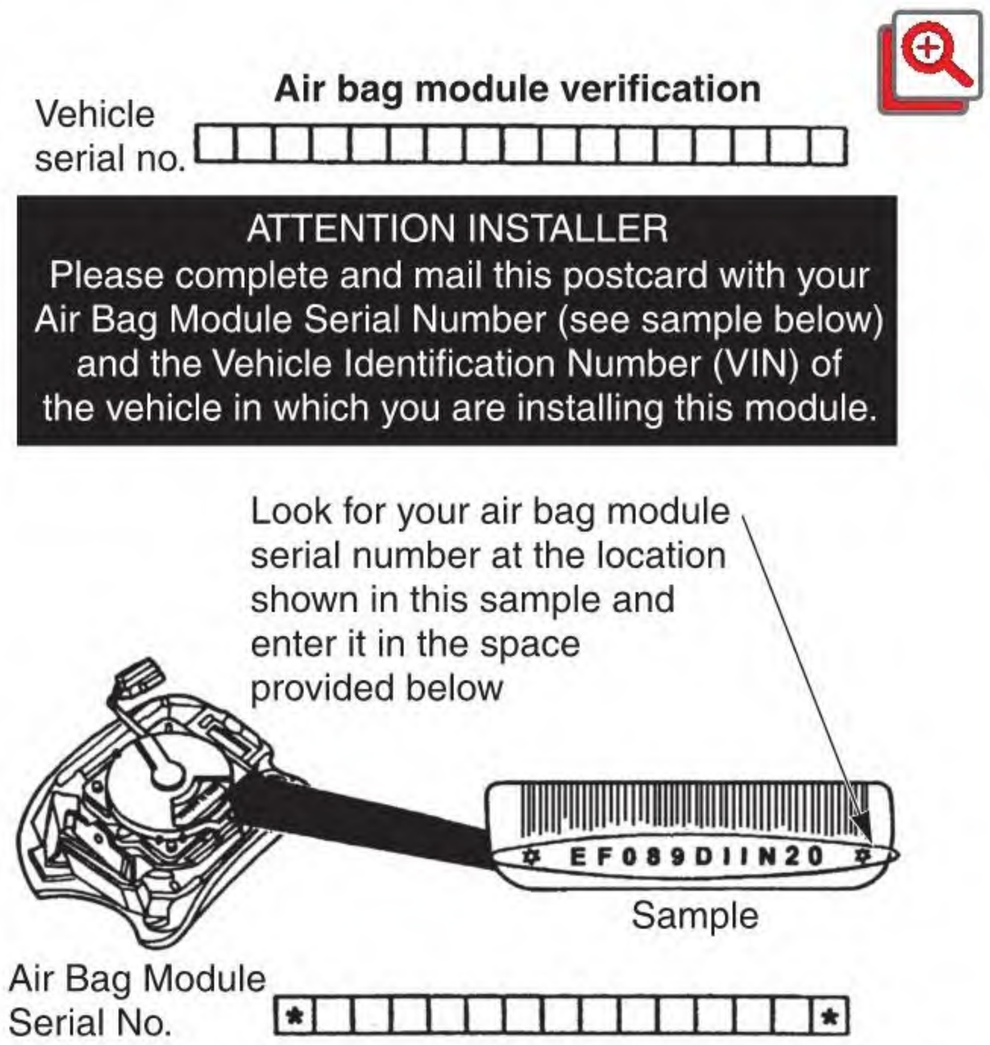
Figure 86-4. Place tape over the air bag vent holes to keep powder from leaking out during removal.

Ford

Figure 86-5. After air bag deployment, use a vacuum cleaner to pick up any powder. Wear safety goggles, rubber gloves, and a respirator. The powder is a skin and eye irritant.

5. Inspect the steering wheel, steering column, and related parts for damage. Parts that have visible damage should be replaced. Damage to the wiring may require wiring harness replacement.
6. Dispose of the air bag as instructed by the manufacturer. In all cases, seal the deployed bag in a large plastic bag, **Figure 86-6**.
7. Wash your hands after being exposed to the air bag powder.
8. A prepaid postage label is usually included with the new air bag. Use this label to ship the deployed air bag to its approved disposal station.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 86-6. After removal, place deployed air bag in plastic bag. Use the label inside new air bag box to ship the old air bag to an approved recycling or disposal center. Never throw the old air bag into the trash.

Air Bag Installation

Obtain the correct replacement air bag module. Make sure the part number on the new air bag is correct. Although air bag modules may look similar, they often have different internal designs. Look at **Figure 86-7**.

Ford

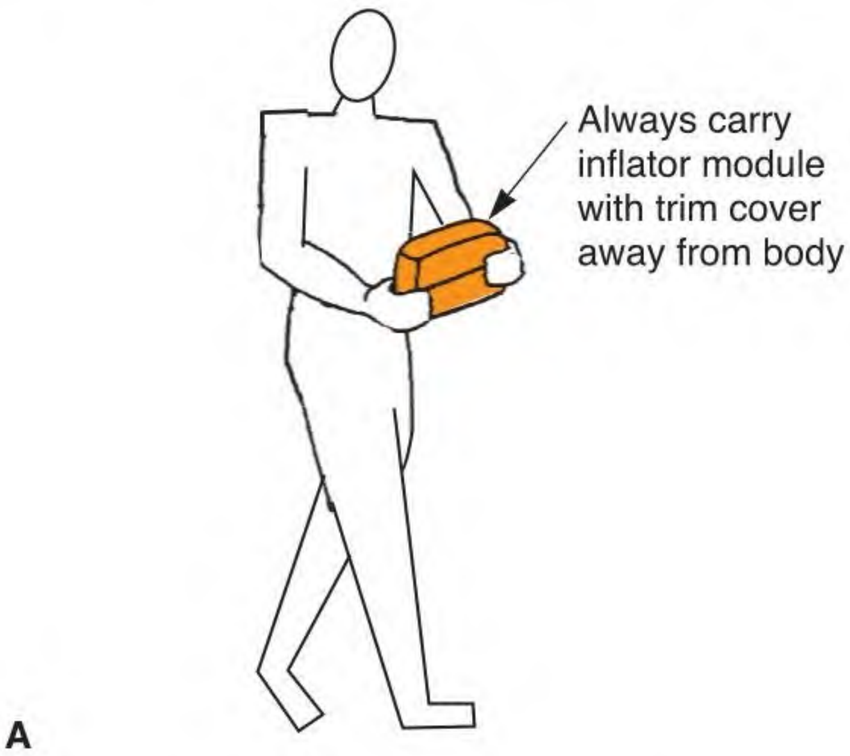


Figure 86-7. Compare part numbers to make sure you have the correct replacement air bag.

Warning

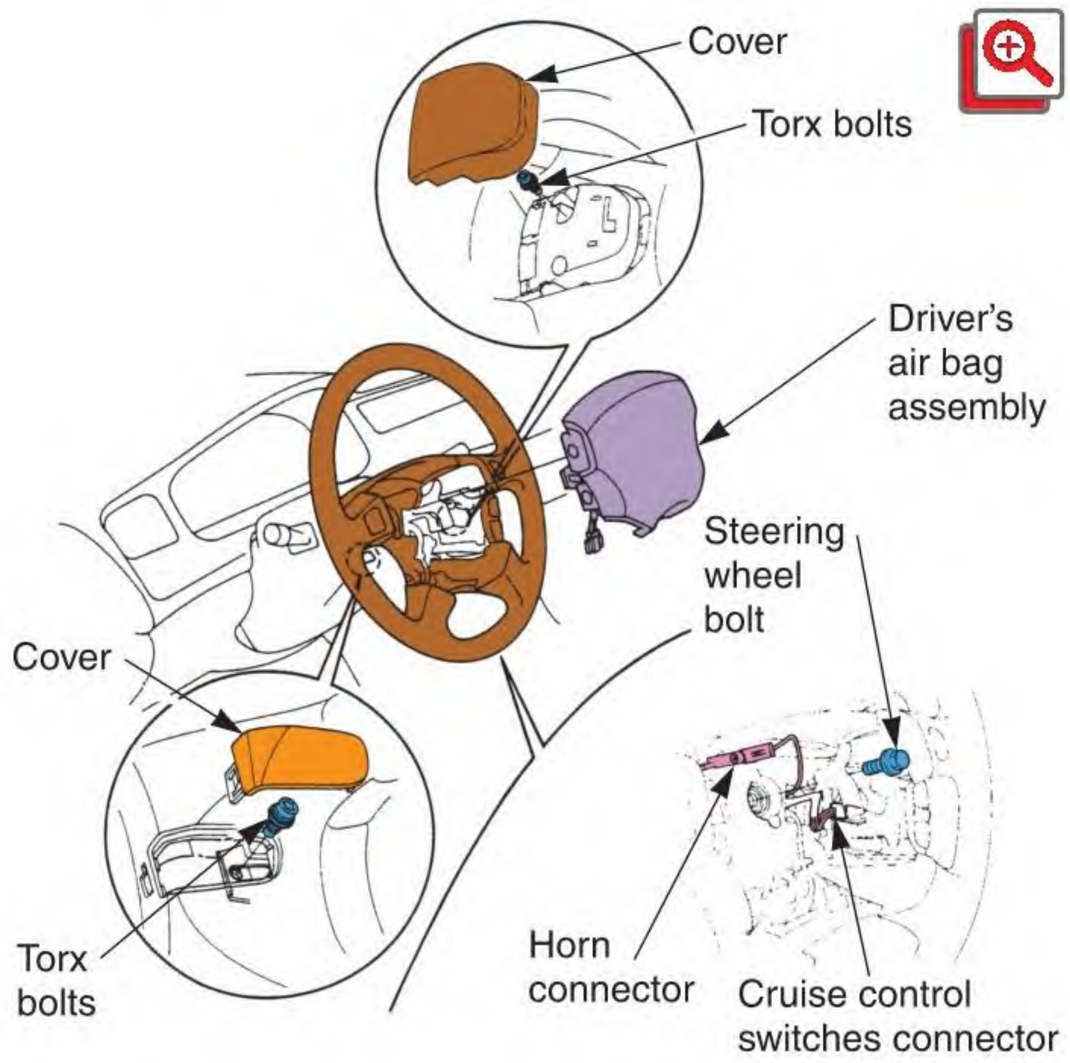
Keep your arms out of the steering wheel spokes and your head to one side of the steering wheel when working on an undeployed air bag. An air bag can shatter bones if accidentally deployed.

When carrying a live (undeployed) air bag module, aim the trim cover or bag away from your body. The metal housing should face your body. This will reduce the chance of injury if the bag accidentally deploys.

When placing the air bag module on a workbench, the bag and trim cover must face up. This will help prevent the module from flying violently through the shop if the bag suddenly inflates. See **Figure 86-8**.

Goodheart-Willcox Publisher

Figure 86-8. A—When carrying a "live" air bag, the trim cover should face away from your body. The metal housing should face your body. B—When placing an air bag on a workbench, the metal housing should face down and the trim cover should face upward.

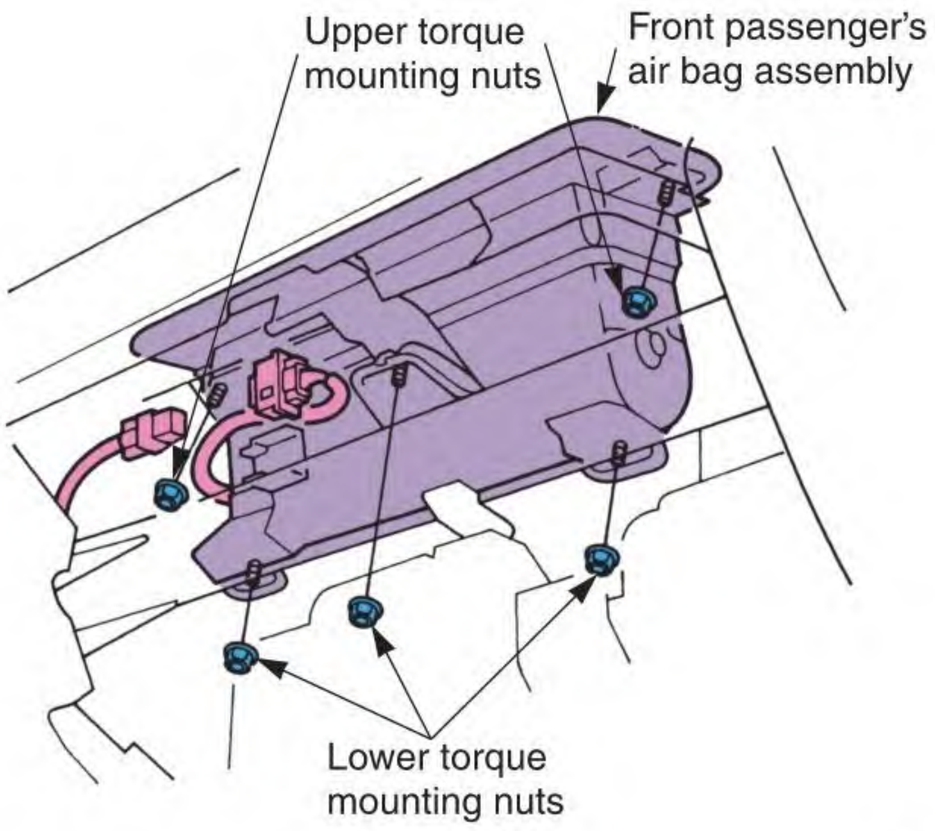


If needed, service the clock spring that connects voltage to the air bag module through wiring in the steering column. In some cases, the steering wheel must be removed to access the clock spring. A wheel puller is normally needed to force the steering wheel off its shaft.

If a clock spring is to be reused, it may have to be centered before it is reinstalled. Failure to properly center the clock spring will result in damage to the internal clock spring wiring. Refer to an appropriate service manual for specific clock spring service procedures.

Before installing the new air bag module, double-check that all sources of voltage are disconnected. You do not want the air bag to deploy when you reconnect its wires in the steering column.

You can then install the new air bag module. While keeping your head to one side of the bag, reconnect its wires. Fit the unit down into the steering wheel. Then, install the small screws that secure the module. Most manufacturers recommend using new screws, since the old ones might have been damaged by deployment. See **Figure 86-9**.



This procedure also applies to the passenger-side air bag. It must usually be secured from under the right side of the dash. Tighten the mounting bolts or nuts to specifications. When reconnecting the wiring harness, keep your body away from the front of the air bag, **Figure 86-10**.

Honda

Figure 86-9. Before installing an air bag module, make sure the source of electricity is disconnected. Then, fit new air bag module into place. Use new fasteners to bolt unit into the steering wheel, if needed. Torque the fasteners to specifications.

Copyright Goodheart-Willcox Co., Inc.

Honda

Figure 86-10. A passenger-side air bag must usually be installed from under the dash. Tighten the nuts to specifications before reconnecting the harness.

Just like driver- and passenger-side air bags, the side-impact air bags found on many vehicles require replacement after deployment or malfunction. The basic steps for replacing a seat-cushion-mounted side air bag are shown in **Figure 86-11**.

Air Bag Sensor Service

After deployment from a collision, some manufacturers recommend replacement of all air bag sensors. By replacing all sensors, you ensure that none are damaged. If you do not replace all sensors, some sensors may remain closed and fire the replacement air bag as soon as power is reconnected.

Refer to the service manual if in doubt. It will give you critical service information: sensor locations, wiring diagrams, and specifications. Air bag sensors are usually located in the front of the engine compartment and under the dash or console in the passenger compartment.

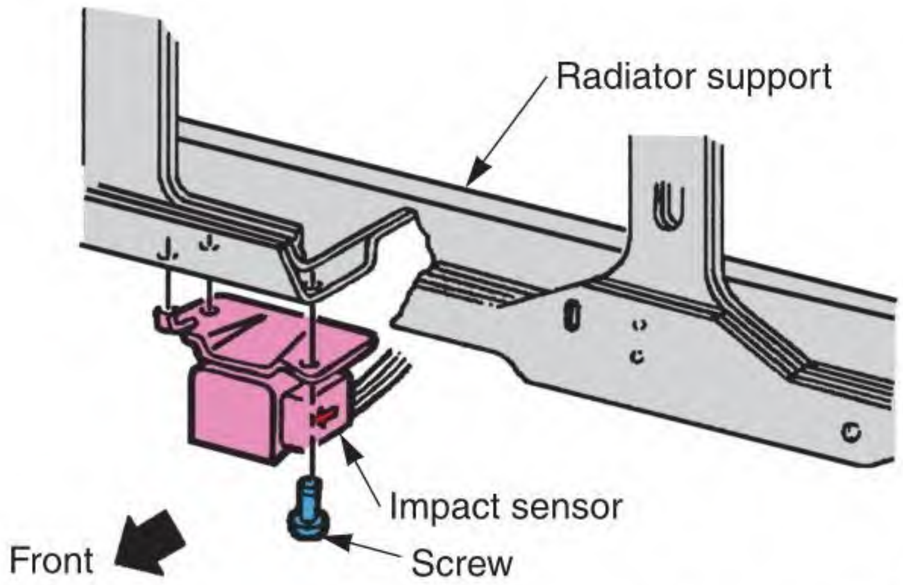
Before replacing any air bag system sensors, make sure the system is disarmed. If you try to remove an air bag sensor with the system armed, the air bag could accidentally deploy—a costly, dangerous mistake.

Disconnect the wiring from the sensor first. Then, remove the screws holding the sensor to the vehicle. Make sure you have the correct replacement sensor.

Any arrow stamped or printed on the sensor must point toward the front of the vehicle. If you install a sensor backwards, the air bag will not deploy during a frontal impact. Tighten the sensor screws properly and reconnect the wiring connector. Refer to **Figure 86-12**.

A

B



C

Goodheart-Willcox Publisher

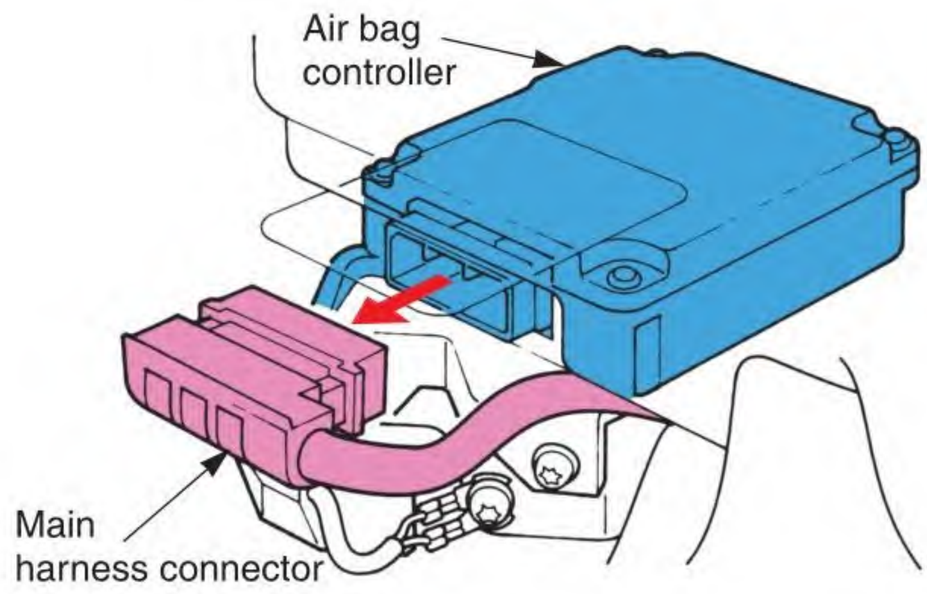


Figure 86-11. A trouble code indicated a bad side-impact air bag. A—A side air bag is typically installed inside the door panel or inside the cushion on the outside edge of each front seat, as shown here. First, remove Velcro or clips from the back of the seat to access the air bag module. B—Disconnect the vehicle battery before carefully unplugging the connection from the old module and plugging in the new one. Before reinstalling the seat upholstery, use a scan tool to make sure you have fixed the problem. C—Correctly position the new side air bag into the slot cut into the seat cushion. Finally, reinstall the upholstery.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 86-12. When replacing sensors, make sure the air bag is disabled so it does not accidentally deploy. Also make sure any arrow on the sensor points toward the front of the vehicle. If you install the sensor backward, the air bag will not work properly.

Honda

Figure 86-13. Follow the service manual instructions when replacing an air bag controller. Some units contain the impact sensor, which can deploy the air bag. Do not damage the connections and be sure to secure the new unit properly.

Air Bag Controller Service

If symptoms or scan tool readings indicate problems with the controller, it should be replaced. Again, make sure the air bag system is disarmed before starting.

Some controllers contain the main impact sensor for the air bag. If you move or jar this type of controller, the air bag could accidentally deploy.

First, disconnect the wiring harness from the controller. Do not force the connector from the controller. Fully release the connector clip and wiggle the plug back and forth while pulling. Do not pull too hard or pry on the connector or you could damage the connector and its pins. Remove the screws that secure the air bag controller to the body panel or bracket. Install the correct replacement controller in reverse order of removal. See **Figure 86-13**.

With everyone out of the vehicle and away from the air bags, rearm the system. Reconnect all harness connectors, install any removed fuses or circuit breakers, and reconnect the battery. On some late-model vehicles, you must reset the air bag system using a scan tool or a special programming tool. In some cases, you must upload new software into the new controller after installation. Follow the manufacturer's instructions.

To check your work, use your scan tool to make a final sweep for trouble codes. Make sure the system is in perfect working order before releasing the vehicle to the customer.

Diagnostic Case Study

Concern: Emmett's Auto Body sends a car over to have the air bag system serviced after a major front-collision repair. The two front air bags deployed during the collision, but the side air bags did not deploy.

Cause: Emmett, the body shop's owner, tells Duff that the impact sensors were replaced when the vehicle was disassembled for repairs. Additionally, the wiring harness near the point of impact was inspected and repaired as needed. Duff relays this information to one of the shop's master technicians. He asks the technician to replace the deployed air bags and make any other repairs needed to return the system to proper operating condition.

Correction: The technician removes the two front air bags and sends them out for proper disposal. She vacuums the passenger compartment to remove the air bag powder residue. She then installs new front air bags and replaces the deployment module according to the service information instructions.

The technician connects a scan tool to the diagnostic connector and verifies that everything is working normally. Since no trouble codes are detected, she releases the vehicle to the body shop.

Copyright Goodheart-Willcox Co., Inc.

Summary

- The proper service of seat belts and air bags is critical to the safety of the vehicle's occupants.
- Seat belt mechanisms should be inspected after an auto accident or after prolonged service.
- A centrifugal belt retractor uses centrifugal force to keep the belt from extending.
- A pendulum belt retractor uses the inertia of a vehicle deceleration to engage the belt locking mechanism.
- Air bag service is needed after deployment or when the air bag indicator light is illuminated.
- Take care to prevent accidental air bag deployment when working.
- If the indicator light glows but the bag is not deployed, use a scan tool to analyze the system.
- To disarm an air bag, all sources of electricity for the igniter module must be disconnected from the air bag module.
- Manual air bag deployment is done by connecting a source of voltage to the air bag module wires to "fire" the air bag.
- After deployment, the air bag must be serviced and disposed of properly.
- Keep your arms out of the steering wheel spokes and your head to one side of the module when working on an undeployed air bag.
- When carrying a live (undeployed) air bag module, aim the trim cover or bag away from your body.
- When placing the air bag module on a workbench, the bag and trim cover must face up.
- After deployment caused by a collision, some manufacturers recommend the replacement of all air bag sensors.
- Any arrow on the air bag sensor must point toward the front of the vehicle.
- If symptoms or scan tool readings indicate problems with the controller, it must usually be replaced.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

air bag powder
centrifugal belt retractor
energy reserve module
manual air bag deployment
pendulum belt retractor

Activities

1. Visit a salvage yard and locate several vehicles with front-end collision damage. While wearing a respirator, safety goggles, and gloves, look for steering wheel and steering column damage. Compare the steering wheel and column damage found on air bag–equipped vehicles to the damage found on vehicles without air bags.
2. Use a service manual to find the locations of impact sensors on different makes and models of vehicles.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Warn customers of the danger of placing _____ in front seats if air bags are installed.
2. Describe the process for inspecting seat belts.
3. List two of the four precautions that should be taken when replacing a seat belt.
4. How do you check the action of a centrifugal seat belt retractor?
5. How do you test the operation of a pendulum-type seat belt retractor?
6. How do you disable an air bag system?
7. Air bag systems are often equipped with an energy reserve module, which can deploy the air bag up to _____ minutes after power is disconnected.
8. How do you manually deploy an air bag?
9. After deployment from a collision or accident, some manufacturers recommend replacement of all air bag sensors. True or False?
10. What will happen if you install an air bag sensor backward?

Copyright Goodheart-Willcox Co., Inc.

ASE-Type Questions

1. Technician A says that it is acceptable to place your arms through the steering wheel spokes when installing a new air bag. Technician B says to place your face directly in front of the air bag during installation. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. An air bag indicator light shows a problem with the air bag system. Technician A says to use a scan tool to help determine the source of the trouble. Technician B says to replace the air bag sensors. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. After air bag deployment, which of the following should *not* be done?
   (A) Force excess powder out of air bag with hand pressure.
   (B) Wear a respirator, goggles, and rubber gloves.
   (C) Place tape over air bag vent holes.
   (D) Vacuum the passenger compartment.
4. When carrying a live (undeployed) air bag module, how should you aim the trim cover?
   (A) Upward.
   (B) Toward your body.
   (C) Toward the floor.
   (D) Away from your body.
5. Technician A says that you may have to replace all the sensors after air bag deployment. Technician B says that the air bag sensor arrow must point toward the front of the vehicle. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Some air bag controllers contain:
   (A) azide pellets.
   (B) the malfunction indicator light.
   (C) the main impact sensor.
   (D) an igniter module.

Restraint System Diagnosis

Condition	Possible Causes	Correction
Indicator does not work.	1. Burned out dash bulb. 2. Circuit problem. 3. Open in inflator module. 4. Controller failure.	1. Replace bulb. 2. Test and repair wiring. 3. Replace module. 4. Replace controller.
Air bag will not deploy during a collision.	1. Failed sensors. 2. Failed air bag module. 3. Bad controller. 4. Wiring problems.	1. Replace sensor. 2. Replace module. 3. Replace controller. 4. Test and repair wiring.
Air bag deploys accidentally.	1. Loose impact sensors. 2. Controller failure. 3. Shorted wires. 4. Moving or hitting sensors while key is on.	1. Tighten sensors, test system. 2. Replace controller. 3. Test and repair wiring. 4. Use approved procedures.
Indicator light comes on.	1. Controller failure. 2. Circuit problem. 3. Bad air bag module.	1. Replace controller. 2. Repair wiring. 3. Replace air bag module.
Seat belt will not engage.	1. Broken spring in retractor. 2. Worn retractor. 3. Failed retractor motor. 4. Circuit problem.	1. Replace retractor. 2. Replace retractor. 3. Replace motor. 4. Repair wiring.
Seat belt will not retract.	1. Twisted belt. 2. Bad retractor. 3. Debris in retractor.	1. Straighten belt. 2. Replace retractor. 3. Remove debris.

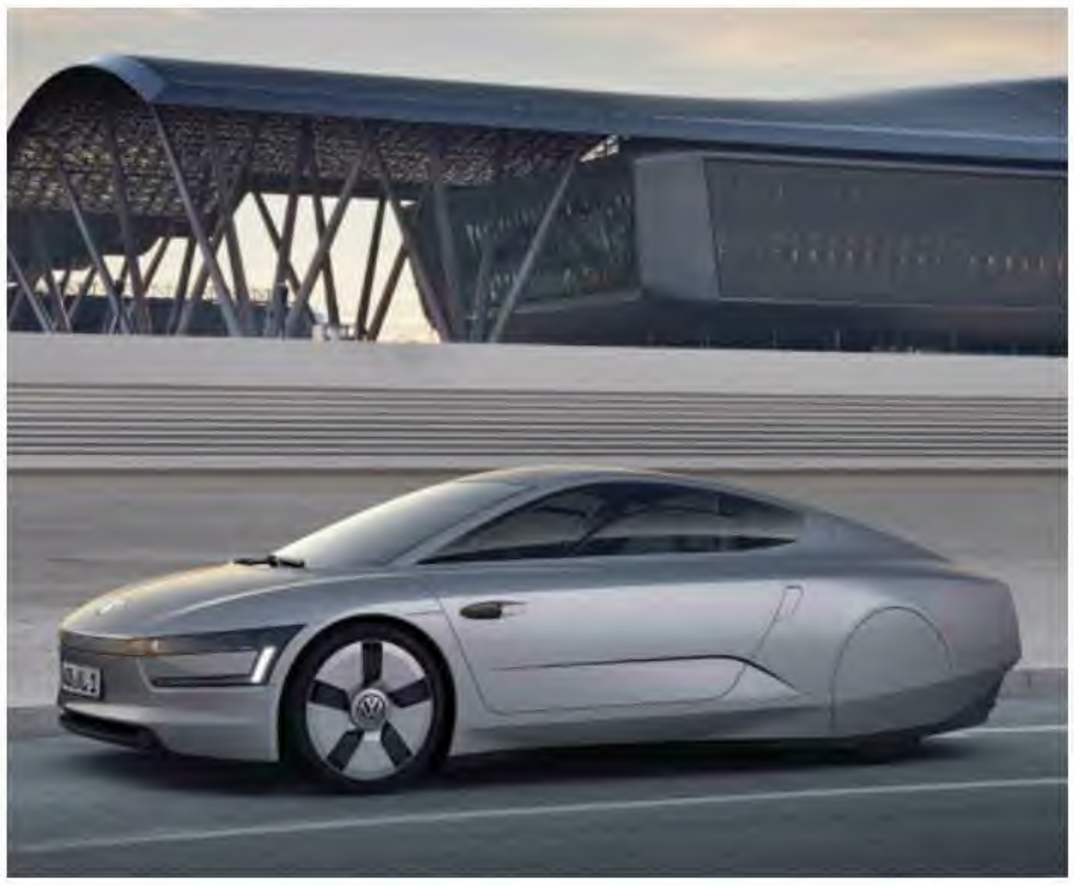
Chapter 87
New and Future Technology

After studying this chapter, you will be able to:

- Summarize developments in vehicle security technology.
- Explain how servo motors have been incorporated into vehicle operation.
- Describe how kinetic energy storage systems work.
- Discuss the various alternate power sources in use and in development for vehicles.
- Explain how composite plastics and metals may be used in future vehicle construction.

This chapter looks to the future of automotive engineering and technology. Automotive technology has seen tremendous change over the years, and more exciting changes are on the horizon. What will the future bring to the passenger vehicle? See **Figure 87-1**. What will happen if we run out of crude oil? What alternate forms of energy could we use? This chapter will address these and other questions.

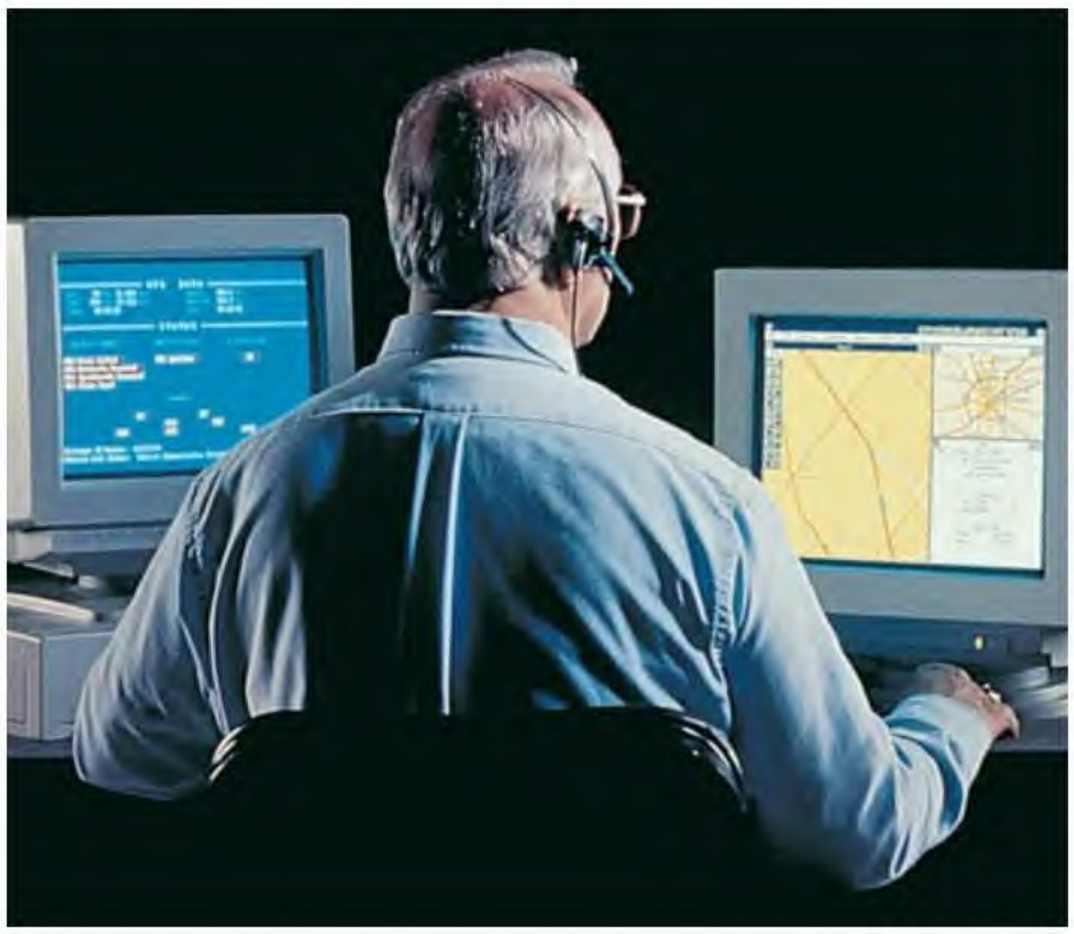
Security Technologies



Advancements in electronics and computer technology have enabled many on-vehicle security features. For example, consider that civilian access to GPS satellites was granted in the 1990s. In no time, GPS technology was incorporated into our everyday lives, including cell phones, tracking devices, and vehicle and pedestrian navigation applications.

Vehicle Tracking Systems

A ***vehicle tracking system*** is a security system that can track the location of a car or truck if it is stolen. One system uses an on-board security control module, a miniature transmitter and receiver, the global positioning satellite (GPS) system, and a 24-hour monitoring/response center, **Figure 87-2**.



If a vehicle with this type of system is stolen, the monitoring center is notified and they transmit a signal to activate the tracking system. Once activated, the control module uses information received from the GPS system to pinpoint the vehicle's location. The system then transmits the location of the vehicle to the monitoring center.

Copyright Goodheart-Willcox Co., Inc.

Volkswagen

Figure 87-1. Changes in the materials used to build and power vehicles, as well as the overall design, can make cars, SUVs, and trucks lighter and more streamlined. These changes will provide a great improvement in fuel/energy economy.

ATX Research

Figure 87-2. A vehicle tracking system includes trained operators available 24 hours a day. If a vehicle is stolen or a driver is in distress, the GPS tracks and locates the vehicle, and the monitoring/response center contacts emergency services with an accurate location of the vehicle.

This type of vehicle tracking system is usually small and self-contained, allowing it to be easily hidden on the vehicle. The tracking system usually incorporates a backup battery, which allows the system to continue receiving and transmitting signals after the vehicle's battery dies or is removed.

Some tracking systems also provide added security for the driver during a carjacking or kidnapping. The driver can press an emergency call button on the key ring, which allows the people at the response center to listen to conversation in the vehicle and to take action as needed. The response center can call the police and tell them the exact location and description of the vehicle. Other systems enable the vehicle to be remotely disabled.

Night Vision Systems

Night vision systems use an infrared camera and monitor system to help the driver's view in fog, snow, rain, and other vision-impairing atmospheric conditions. The camera could be mounted in the front grille. When activated in bad weather or at night, the camera produces an image on the dash-mounted monitor or on a heads-up display on the windshield. This lets the driver see longer distances through outside conditions, like fog, to detect oncoming vehicles, people, curves in the road, and other dangers.

Vehicle Operation Technologies

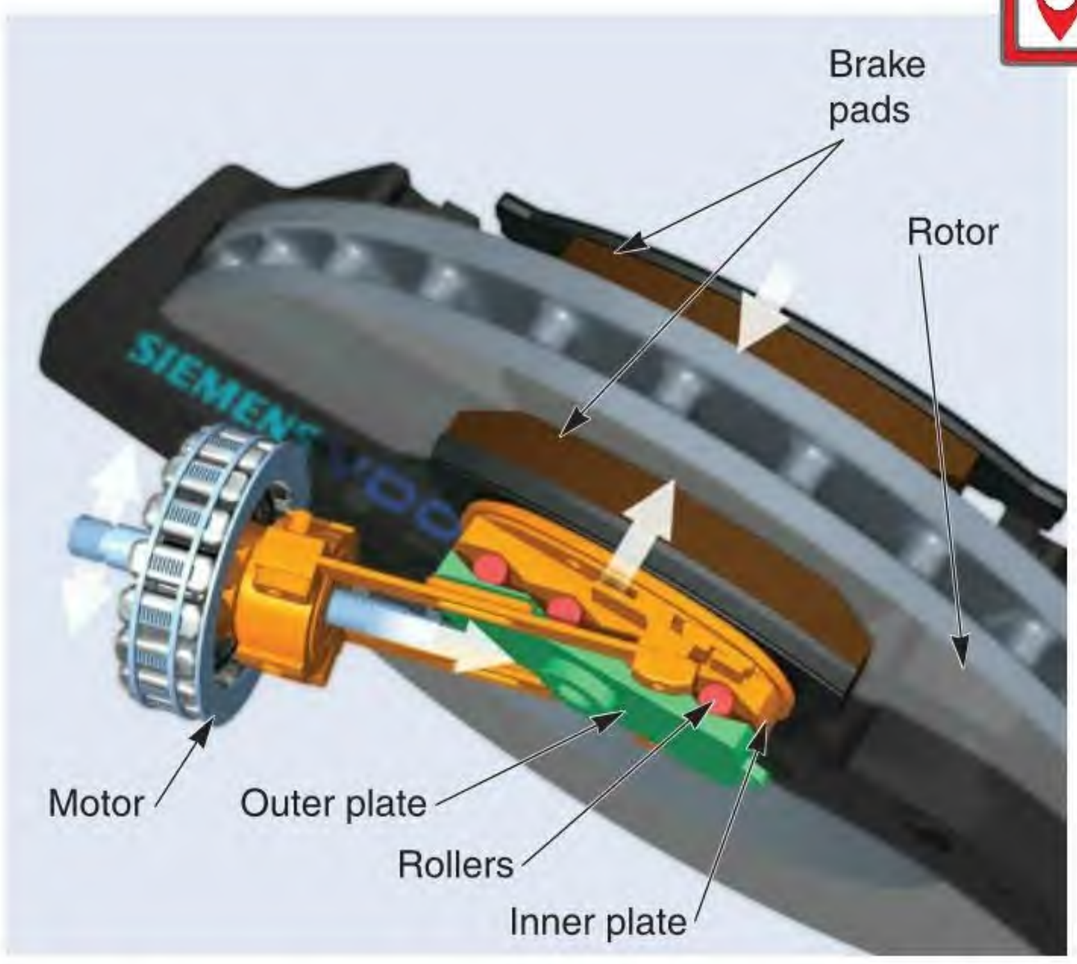
Advancements in both electronics technology and environmental consciousness have prompted changes in how a vehicle operates, as well as features offered to consumers.

Electric Brake Calipers

An ***electric brake caliper*** uses one or more servo motors to force the brake pads into the rotating brake disc to slow and stop the vehicle. This type of caliper eliminates the need for the brake system hydraulic components (master cylinder, brake lines, hoses, etc.).

When the driver presses the brake pedal, a sensor on the brake pedal sends a signal to the braking computer. The computer then sends an electric control current to each electric brake caliper to turn on the servo motor actuator(s). When the servo armature rotates, it turns a screw-type mechanism to force the inner plate and brake pad into the rotor. The rotor pulls the pad and inner plate in the direction of rotation, wedging the rollers between the inner plate and the stationary outer plate. The wedging action then forces the brake pads tighter against the spinning

Copyright Goodheart-Willcox Co., Inc.



rotor to increase friction and decrease speed. See **Figure 87-3**.

When the brake pedal is released, the computer reverses servo motor rotation to release clamping force on the rotor. The ECM can apply different amounts of electrical current to each wheel to control how much braking force is applied at each wheel.

Total electronic control of brake system is ideal for ABS, stability control, collision avoidance, and other computer-controlled systems. Electronic brake systems are much lighter than hydraulic brakes, helping to reduce fuel consumption, **Figure 87-4**.

Electric Parking Brake

An ***electric parking brake***, or electric emergency brake, uses a dash-mounted switch and an electric servo motor to mechanically apply the rear brake. When the parking brake servo motor is energized, it rotates a worm gear that acts on a lever mechanism to pull on a mechanical arm and cable mechanism. The cable mechanism forces the brake pads or shoes into the rotors or drums to keep the vehicle from rolling. When the parking brake is shut off, the servo motor reverses to allow the brake pads or shoes to retract so the vehicle can be driven.

Siemens

Figure 87-3. An electric brake caliper. The servo motor forces the inner plate and brake pad into the rotor. The spinning rotor moves the pad and inner plate in the direction of rotation, wedging the rollers between the inner and outer plates.

Goodheart-Willcox Publisher

Figure 87-4. Auto manufacturers are developing all-electric brakes for vehicles. Electric brakes provide shortened application times, more precise clamping force, reduced unsprung weight, and other benefits of a computer control system.

Kinetic Energy Recovery System (KERS)

A ***kinetic energy recovery system (KERS)*** can capture kinetic energy generated during vehicle braking and store the energy to assist in vehicle acceleration from a standstill. These types of systems use either a flywheel mechanism (mechanical) or a battery (electrical) to store the energy captured until it is needed.

In the mechanical KERS design, the kinetic energy generated during vehicle braking spins a composite steel flywheel mounted in the vehicle's hub at speeds up to 100,000 rpm. When an acceleration boost is needed, the spinning energy of the flywheel is connected to the rear wheels of the vehicle to temporarily supplement engine power. See **Figure 87-5**.

In an electrical KERS design, the system converts the kinetic energy generated during vehicle braking to electrical energy. The electrical energy is stored in a battery until it is released/engaged by the driver.

Automatic Tire Wear Adjustment

Future vehicles might have automatic tire wear adjustment systems, which could eliminate the need to rotate the tires. Automotive engineers could use the anti-lock brake sensors to monitor tire and wheel speed. If one

Copyright Goodheart-Willcox Co., Inc.

Volvo

Figure 87-5. An experimental drive axle-mounted KERS. A special transmission is used to transfer torque from the flywheel to the CV-drive axles.

tire is worn, it would be slightly smaller in diameter than the others. The computer would detect a higher signal frequency from the wheel sensor monitoring the rotation of the worn tire. The computer could then adjust the differential solenoids to apply more pressure to one side of the differential clutch pack upon acceleration. This would lower tread loss on the worn tire. More torque could be applied to the tire or tires with more tread to progressively even out tire wear.

Alternate Power Sources

Alternate power sources are other methods of producing energy (other than from gasoline and diesel oil) to propel a motor vehicle. The most promising include electric vehicles, hybrid vehicles, hydrogen fuel engines, and flexible-fuel vehicles.

Electric Vehicles

An electric vehicle uses a large, high-efficiency electric motor and large storage batteries to power the automobile and reduce air pollution from burning fossil fuels. They provide a viable, alternate means of vehicle propulsion for short trips. The driver simply plugs the electric car into a recharging station to re-energize the storage batteries and ready the car for another commute, **Figure 87-6**.

Audi

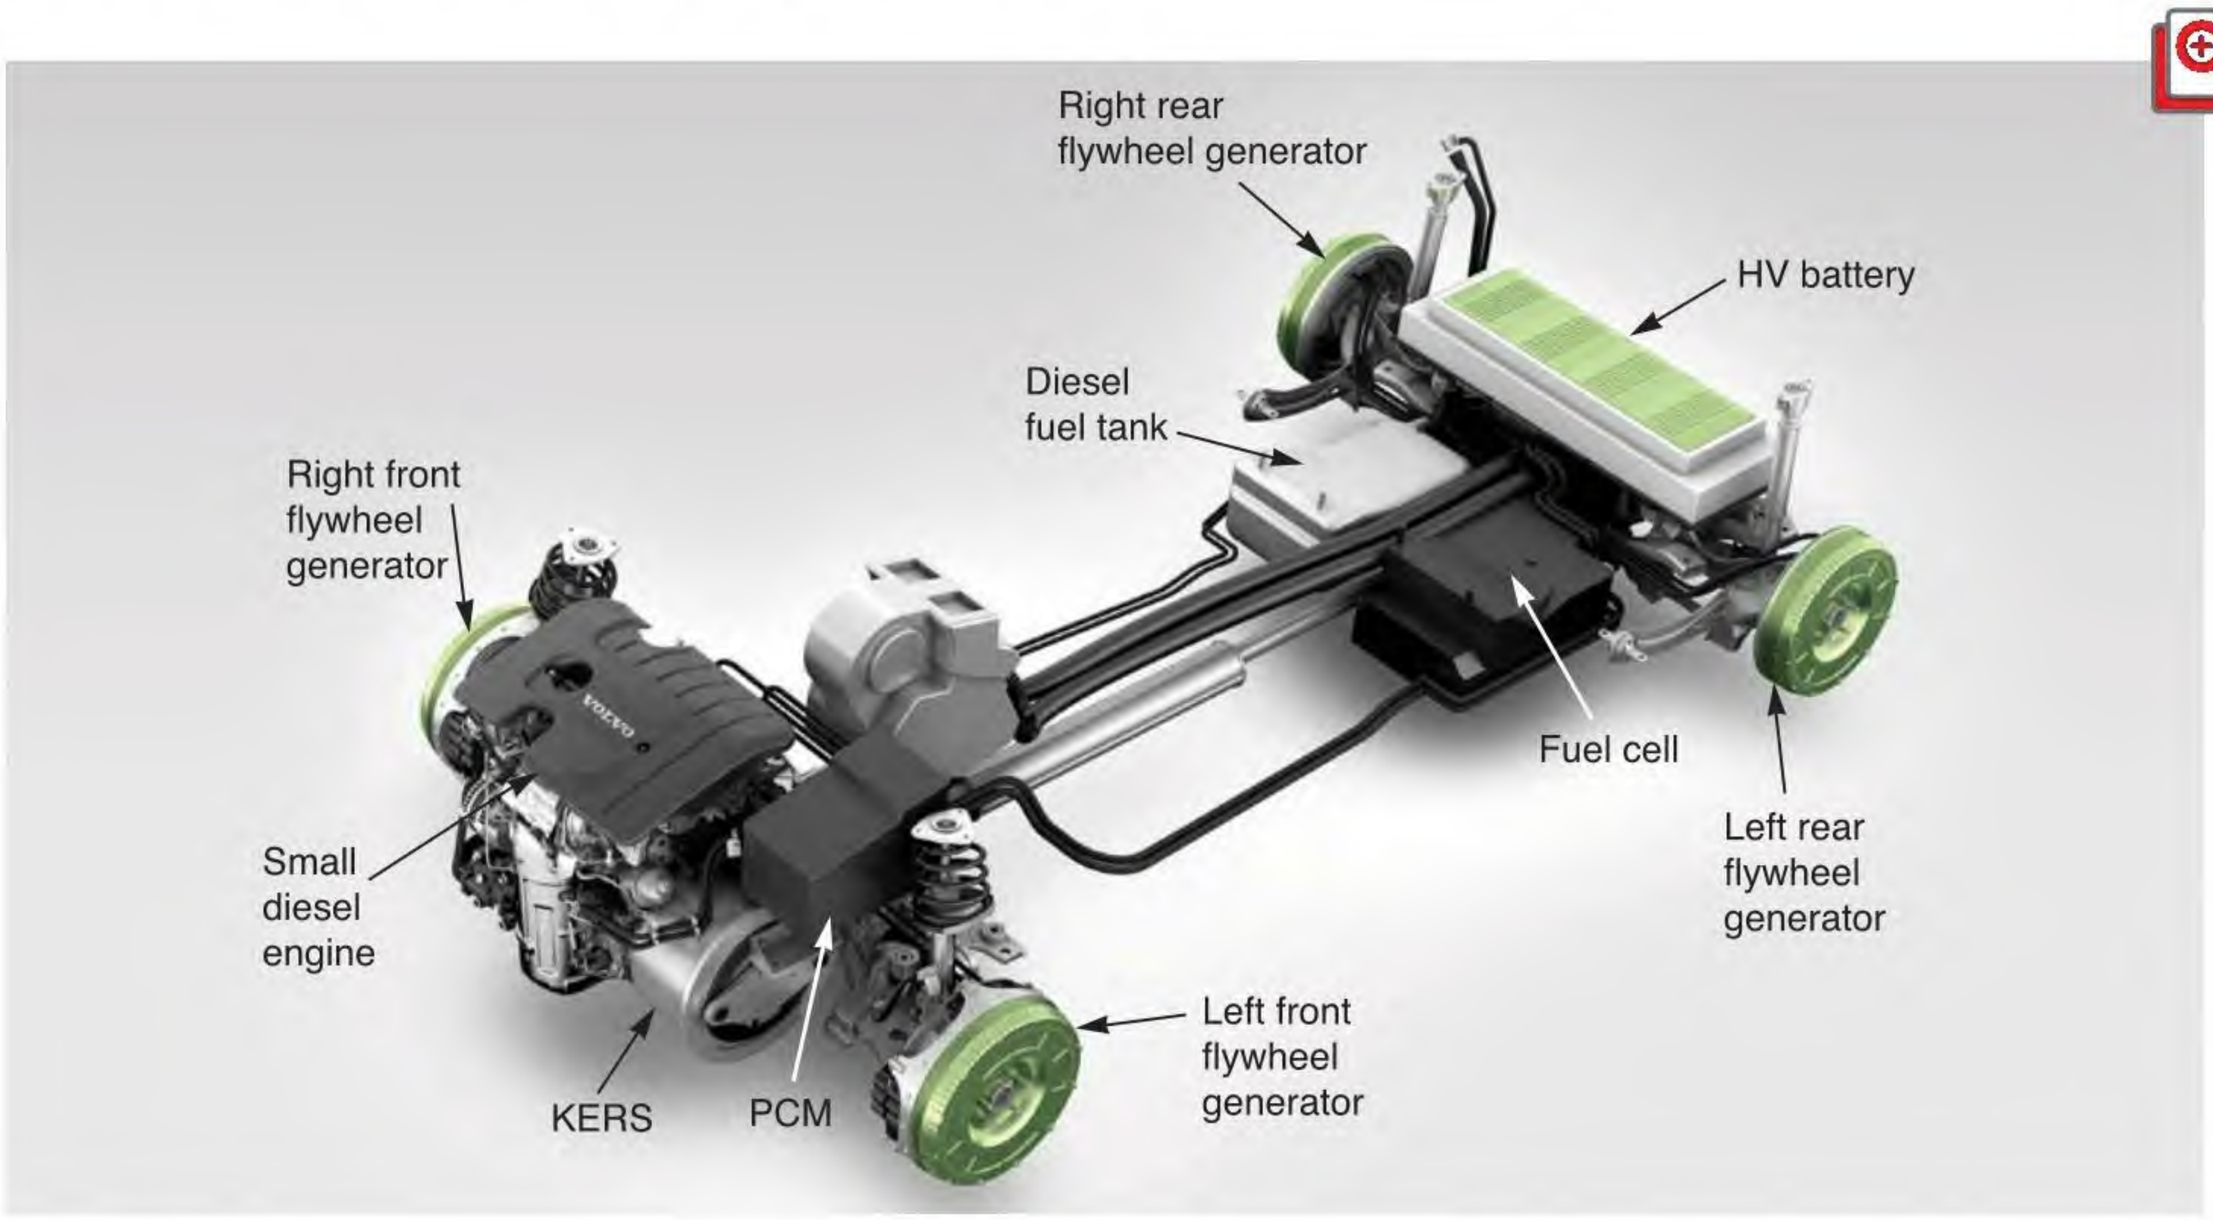
Figure 87-6. Power companies and large corporations are working together to provide electric vehicle charging stations in convenient locations.

Copyright Goodheart-Willcox Co., Inc.

Lithium polymer batteries can be formed into almost any shape for saving space in a vehicle's design. The lithium polymer cells are made from flexible laminate film that can measure as little as 100 microns thick. The laminate is made of metal foil, electrolyte, cathode, anode, and insulator layers. This battery design offers high energy density and low manufacturing costs.

One drawback involved with electric vehicles is the large number of power generating stations needed to recharge the millions of batteries every night. Building all the generating stations would create environmental pollution from burning much more coal, oil, or nuclear power. Battery recharging itself can also cause some pollution from the battery gases generated.

Flywheel Generator Hybrids

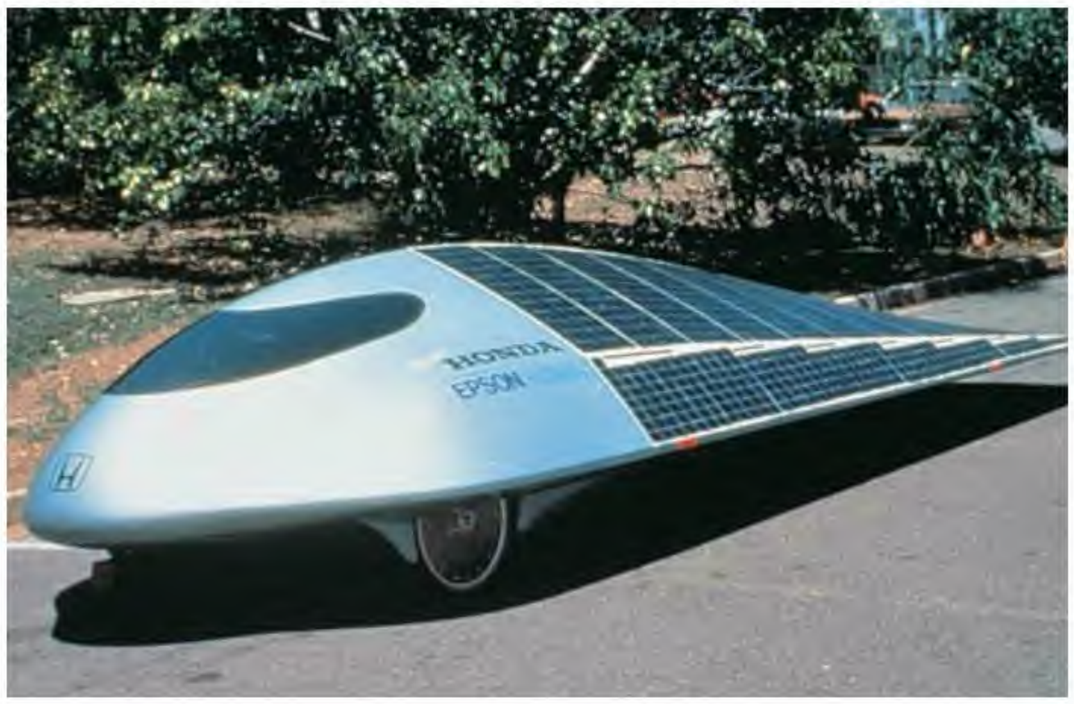


A flywheel generator drive system is a direct electric wheel drive design that eliminates the power lost from having to spin or rotate the transmission gearset and a differential assembly in heavy gear oil. Electromagnetic coils are mounted on the bearing hubs with permanent magnets embedded in the spinning wheel. Four flywheel generators are used to rotate or stop the four wheels and tires directly. This system eliminates the need for friction brake pads and large rotors that waste the energy needed to bring the car to a stop by generating heat. Refer to **Figure 87-7**.

The problem with flywheel generator drive systems is that they increase the unsprung weight and ride harshness on rough roads. Since the four flywheel generators add weight to the outer ends of the suspension control arms, the vehicle body/frame shudders or shakes more when the flywheel generators move up and down with road surface imperfections.

Solar Vehicles

A ***solar vehicle*** uses solar panels to generate electricity for propulsion. A large surface area of the vehicle body is covered with solar panels, which convert sunlight directly into electric current. The current powers an electric motor, which powers the vehicle.



Someday, maybe the whole surface of the hood, roof, and trunk could be covered with solar panels that are coated with a painted clear coat. See **Figure 87-8**. The electric current from the solar panels could be stored in the HV battery. The hybrid PCM could step up the low solar cell voltage into high voltage for recharging the HV battery. This would eliminate the need to recharge the vehicle at a charging station. So, the battery would charge for free.

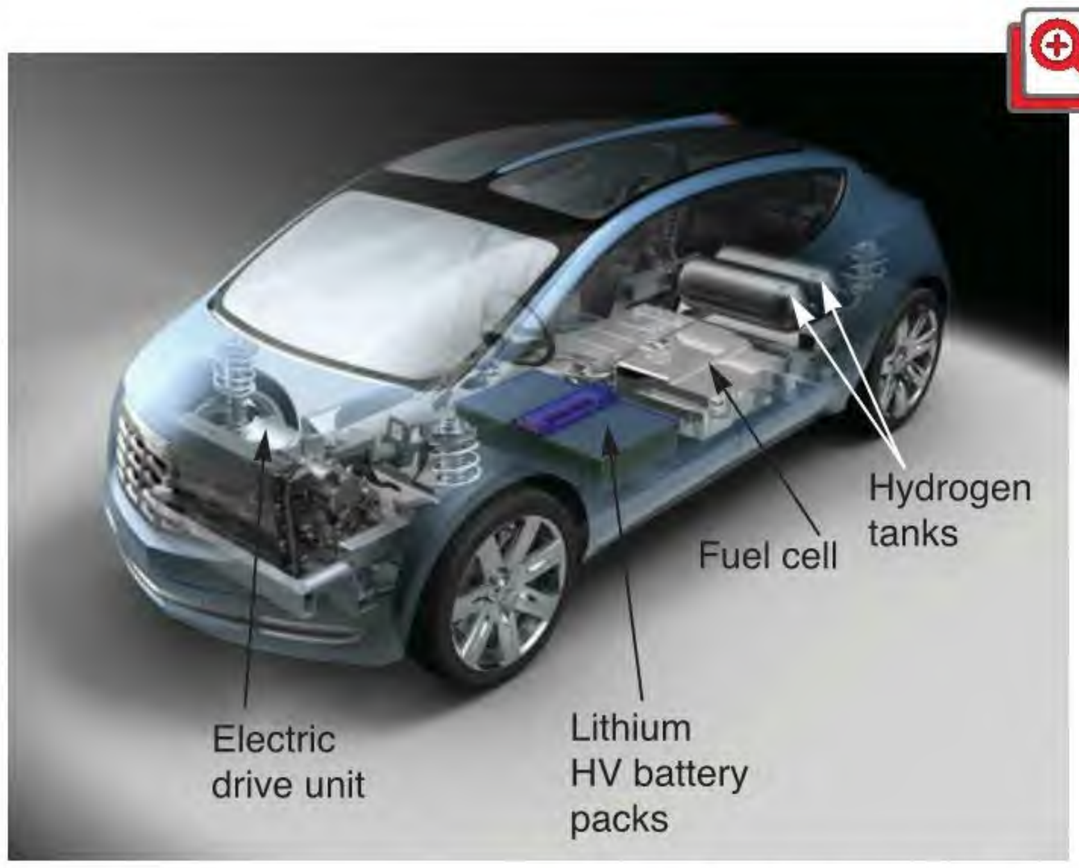
Volvo

Figure 87-7. This experimental powertrain uses a small diesel fuel engine, a KERS, fuel cell, four flywheel generators, and an HV battery.

Copyright Goodheart-Willcox Co., Inc.

Honda

Figure 87-8. A solar vehicle is powered completely by sunlight. This technology could someday be incorporated into a hybrid vehicle.



Hydrogen Fuel

Hydrogen burns with no harmful emissions—water vapor is the only by-product of combustion. The process of electrolysis can be used to convert ocean salt water into pure hydrogen and oxygen. ***Electrolysis*** sends electric current through water (H_2O), which separates the two atoms of hydrogen (H) from one atom of oxygen (O) into separate gases. If ignited, the hydrogen and oxygen atoms will burn and vibrate at high temperatures while changing back into water vapor.

Producing hydrogen fuel is currently too expensive using conventional sources of energy. However, hydrogen fuel production using low-cost wind or solar energy to process salt water would give us a very desirable new fuel source. With a hydrogen storage and gas metering system, engines would be just as powerful, but would operate much more cleanly, with no adverse effects on our atmosphere and climate. See **Figure 87-9**.

Fuel Cell

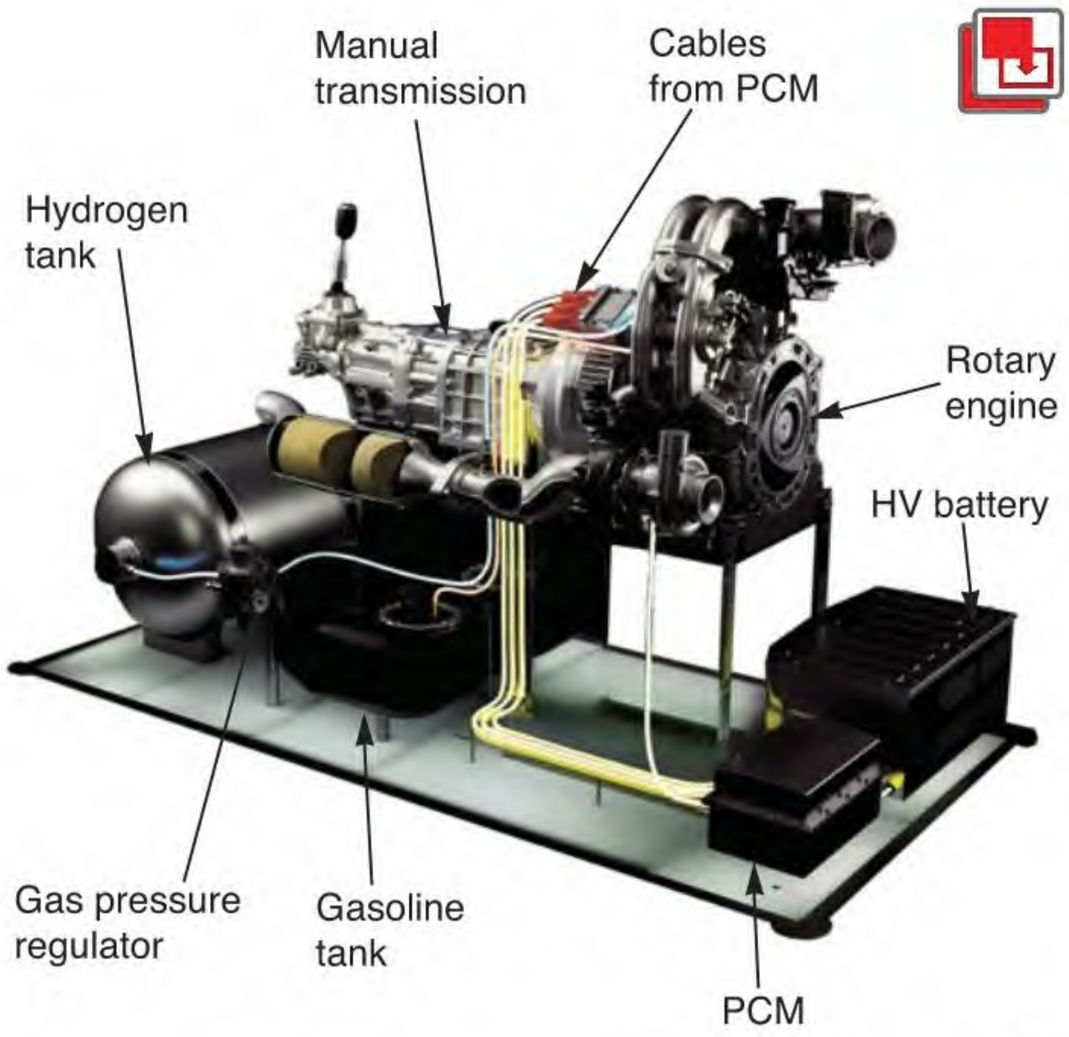
A ***fuel cell*** combines hydrogen and oxygen to produce electrical energy. It is electrolysis in reverse. A fuel cell is made of a plastic, gas-permeable membrane coated with a catalytic platinum foil. This membrane is sandwiched between two electrode plates. Hydrogen gas flows through the anode plate and the membrane, while compressed air flows the other way. The catalyst causes the hydrogen gas to separate into positive hydrogen ions (protons) and electrons.

Goodheart-Willcox Publisher

Figure 87-9. This hybrid crossover vehicle uses a small turbine engine, an electric motor, lithium HV battery, and hydrogen gas tanks for a fuel cell battery to produce a tremendously powerful propulsion system that can operate for hundreds of miles before refueling or recharging.

This causes a potential difference of electrical energy across the anode and cathode. When current is drawn out of the fuel cell, oxygen molecules separate and combine with hydrogen ions to form water and heat.

Flexible-Fuel Vehicles



Flexible-fuel vehicles (FFV) are designed to operate on different types of fuel. Sensors monitor the contents of the fuel through measurement of combustion efficiency, and engine functions are adjusted for maximum efficiency for the type of fuel being consumed. A flex fuel rotary engine (no reciprocating pistons) is shown in **Figure 87-10**.

Gas Turbine

Gas turbines are alternate types of engines that can burn a wide variety of fuels: gasoline, kerosene, or oil. A gas turbine can produce tremendous power for its size. Because of the spinning action, its power output is very smooth.

Gas turbines are not currently in use due to high manufacturing costs and poor fuel efficiency. They require many special metals, ceramic parts, and precision machining and balancing. Someday, with improvements in efficiency through engineering advances, the gas turbine may be a very common automotive engine.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 87-10. This hybrid propulsion system uses a smooth running, high-speed rotary engine (no reciprocating pistons) and a motor generator to operate a manual transmission in a sports car.

Plant Fuels and Lubricants

As the world's petroleum reserves dwindle, the prices of petroleum-based fuels are bound to rise. This has prompted many researchers to consider fuels derived from plant life. Since plant life is relatively abundant and renewable, many consider this a promising area of research.

Plant fuel research has led to the development of biodiesel fuel. Biodiesel can be created from animal fats or vegetable oils (including waste oils and grease from restaurants). Biodiesel can be used in current diesel engines without modification. This fuel has the benefit of coming from a renewable source. It is also cleaner burning than petroleum diesel fuel.

Ethanol is another plant fuel that is already in wide use. Currently, small quantities of ethanol are blended with gasoline to increase its octane and reduce emissions. However, car manufacturers are developing flexible fuel cars that can run on fuel containing a much higher concentration of ethanol.

Synthetic motor oil has been created from farm-grown plants and vegetables, and performs as well as crude oil-based lubricants. Tests show that motor oil made from natural plant or vegetable oils can be formulated to have equal or better high and low temperature lubricating performance as carbon- or petroleum-based oils.

Future Vehicle Construction

Vehicle curb weight reduction is the most important factor in further improving fuel economy. In the future, almost every part of a passenger vehicle will contain light and strong composite plastics and metals. For example, engine block strength is increased by casting composite webbing into cast iron and aluminum parts. The synthetic netting is placed inside the mold for the part.

Body panels on cars are now being made of lightweight aluminum, fiberglass, or carbon fiber. A-pillars on the side of the windshield can be made of high-strength steel with carbon fiber core tubes for added stiffness during a vehicle roll-over accident.

Tech Tip

Do not overtighten fasteners on carbon fiber or plastic parts. Only a few foot pounds of torque are required to secure plastic and carbon fiber parts.

Some automakers are experimenting with ***inflatable door impact beams***. A powerful pyrotechnic charge is used to expand the metal beam so it balloons out to a larger diameter. This larger beam diameter can withstand more violent collisions from the side without intrusion into the driver or passenger seat area.

Future Systems

What automotive design changes will we see in the next century or two? Just look at the advances the human race has made in the last 100 years! We have gone from the horseless carriage to the hybrid passenger vehicle, and from experimenting with human flight to traveling beyond the moon in one human lifetime. Since human progress is increasing exponentially, we should see even more rapid technical progress in the future. As a result, your job as a professional auto technician will become even more important and in-demand.

We have the technology to reduce the impact of passenger vehicles on the environment and atmosphere. The change from R-12 refrigerant to R-134a has reduced the negative effect on Earth's atmosphere.

Copyright Goodheart-Willcox Co., Inc.

In the future, regulations could require another change from R-134a refrigerant to the naturally occurring atmospheric gas, CO_2. Carbon dioxide has proven to be a very efficient refrigerant and is more "ecofriendly" when compared to other non-ozone-depleting refrigerants. Hybrid gas/electric propulsion systems are also a big step in the right direction for the future of our planet and our driving experience.

In addition, recycling is becoming more standard in practice in the automotive industry. It may increase to the point that we build whole car bodies out of recycled aluminum cans. A car body made out of "old soda pop cans" will be a strong, lighter vehicle that resists corrosion much better than steel.

Industry Trend

The fuel cell vehicle offers a glimpse into the future of automotive technology. Several major automobile and truck manufacturers are experimenting with fuel cell technology. The fuel cell is highly efficient and emits very few or no toxic emissions, depending on the fuel used. Learn all you can about fuel cell technology. There is a good chance you will be servicing fuel cell vehicles sometime in the future.

Summary

- Advancements in electronics and computer technology have enabled many on-vehicle security features, including vehicle tracking systems and night vision systems.
- The use of servo motors in an electric brake caliper eliminates the need for the brake system hydraulic components.
- A dash-mounted switch energizes the electric parking brake servo motor to mechanically apply the rear brake.
- Kinetic energy recovery systems can capture kinetic energy generated during vehicle braking and store the energy to assist in vehicle acceleration.
- Alternate power sources are other methods of producing energy (other than from gasoline and diesel oil) to propel a motor vehicle.
- Electric vehicles use an electric motor and storage batteries to power the automobile and reduce air pollution from burning fossil fuels.
- A flywheel generator drive system is a direct electric wheel drive design that eliminates the need for friction brake pads and large rotors.
- A solar vehicle uses solar panels to generate electricity for propulsion.
- Hydrogen burns with no harmful emissions—water vapor is the only by-product of combustion.
- A fuel cell combines hydrogen and oxygen to produce electrical energy.
- A flexible-fuel vehicle (FFV) is designed to operate on different types of fuel.
- Plant fuel research has led to the development of biodiesel fuel, ethanol, and synthetic motor oil.
- Vehicle curb weight reduction is the most important factor in further improving fuel economy.
- Since human progress is increasing exponentially, we should see even more rapid technical progress in the future.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

alternate power sources
electric brake caliper
electric parking brake
electrolysis
flexible-fuel vehicles (FFV)
fuel cell
inflatable door impact beams
kinetic energy recovery system (KERS)
night vision systems
solar vehicle
vehicle tracking system

Activities

1. Research articles and other information on future automotive technologies. Create a presentation to report your findings.
2. Research the production of hydrogen gas from saltwater. Write a report on the current state of production. Include information on the potential use of solar energy in production.

Copyright Goodheart-Willcox Co., Inc.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Describe the operation of a typical vehicle tracking system.
2. Night vision systems use a(n) _____ camera and monitor to help the driver's view during vision-impairing weather conditions.
3. What is the function of servo motors in relation to an electric brake caliper?
4. Describe the role of servo motors in an electric parking brake.
5. How does a KERS assist in vehicle acceleration?
6. A(n) _____ battery offers high energy density and low manufacturing costs.
7. How is electrolysis used to produce hydrogen fuel?
8. Automobiles designed to operate on different types of fuel are called _____.
9. _____ is an alternative fuel created from animal fats or vegetable oils and used in current diesel engines without modification.
10. Describe how composite plastics and metals can be used to improve fuel economy.

ASE-Type Questions

1. Technician A says advancements in electronics technology have led to changes in how a vehicle operates. Technician B says that increased environmental consciousness has prompted changes in how a vehicle operates. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says all kinetic energy recovery systems use a flywheel mounted in the vehicle's hub. Technician B says kinetic energy recovery system designs can be either mechanical or electrical. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says lithium polymer cells are made from incredibly thin flexible laminate film. Technician B says lithium polymer cells are made of metal foil, electrolyte, cathode, anode, and insulator layers. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. The process of _____ can be used to convert ocean saltwater into pure hydrogen and oxygen.
   (A) conversion
   (B) combustion
   (C) electrolysis
   (D) vaporization
5. Which of the following is blended with gasoline to increase its octane and reduce emissions?
   (A) Ethanol.
   (B) Lubricants.
   (C) Biodiesel.
   (D) Hydrogen.

Wire Size Chart

The selection of the correct gage primary wire is very important for automotive and other low-voltage applications to ensure safe and reliable performance.

When too small a gage primary wire is used, a voltage drop occurs due to electrical resistance. On lighting equipment there is also a loss of candlepower (visible light measurement).

The two factors that should always be considered in selecting an adequate gage primary wire are (1) the total amperage the circuit will carry and (2) the total length of wire used in each circuit, including the return.

Select the correct gage wire from the wiring diagram and primary wiring guide below. Allowance for the return circuits, including grounded returns, has been computed on the recommendations below. The length cable should be determined by totaling both wires in a two-wire circuit.

Total Approx. Circuit Amperes	Total Circuit Watts	Total Candle-power	Wire Gage (for length in feet)											
12V	**12V**	**12V**	**3'**	**5'**	**7'**	**10'**	**15'**	**20'**	**25'**	**30'**	**40'**	**50'**	**75'**	**100'**

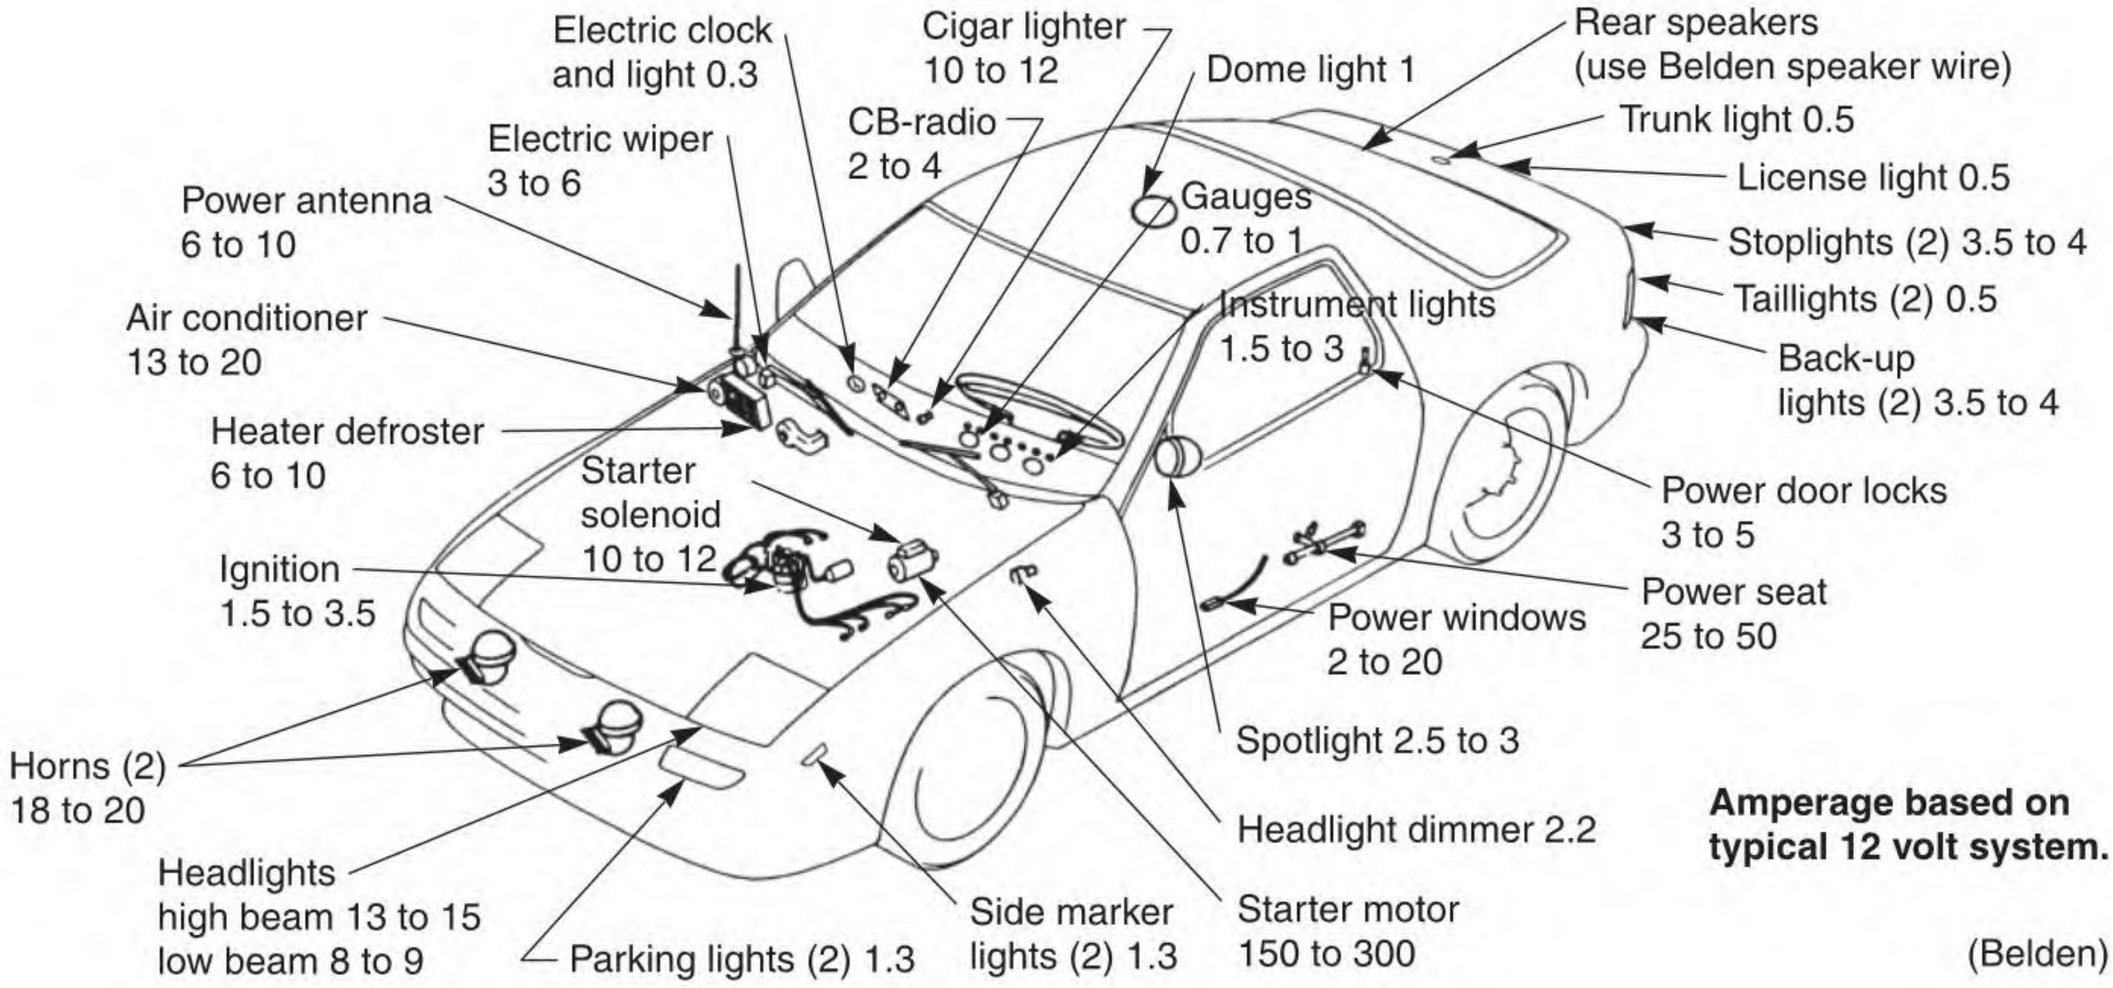
*18 AWG indicated above this line could be 20 AWG electrically—18 AWG is recommended for mechanical strength.

How to use chart



1
Measure Length of Wire in Circuit—chart applies to ground return. Two-wire circuits will be total of both wire lengths. Be sure to indicate both vehicles on auto and trailer applications.

2
Find the total amperes, watts, or candlepower and choose nearest value in proper column.

3
Move horizontally to proper footage column and find nearest wire gage.

4
For 6 volt applications, use two wire sizes larger. Example: If chart shows 16 ga. for 12 volt system, use 14 ga. on 6 volt system.

Based on maximum of 10% voltage drop

Amperage based on typical 12 volt system.

(Belden)

Glossary

12-volt battery: Electrochemical device that produces and stores electricity. An automotive battery is a 12-volt battery with six cells, which produce 12.6 volts to power the vehicle's 12-volt main electrical system.

12-volt starting system: System using a 12-volt battery and an electric motor to turn the engine crankshaft for engine operation.

A

A/C switch: Driver-operated switch in the car's dash that feeds current to the compressor clutch and other electric components of a vehicle's air conditioning system.

abbreviations: Letter combinations that stand for words. Abbreviations are used extensively in the automotive industry.

abnormal combustion: Problem that occurs when combustion happens too quickly or too slowly. The resultant flame does not spread evenly and smoothly through the combustion chamber.

abrasive pad: A cleaning tool with a surface of coarse material. It can be attached for use in an air or electric drill and is helpful in removing old gasket material.

ABS: Abbreviation for Anti-lock Braking System.

ABS actuator: See *ABS electro-hydraulic modulator.*

ABS control module: An ECM that uses wheel speed sensor inputs to control the operation of the electro-hydraulic modulator.

ABS electro-hydraulic modulator: Regulates the fluid pressure applied to each wheel brake assembly during periods of hard braking. It is also called an ABS actuator.

ABS warning light: Amber indicator lamp mounted in the instrument cluster. It illuminates when there is a problem with the anti-lock brake system.

absorbed glass mat battery: Type of sealed lead-acid battery that contains fiber matting which absorbs liquid electrolyte and holds it between the battery plates. It is also called an ABG battery.

ac generator: Machine that produces electricity using a spinning magnetic field (rotor) within a stationary set of windings (stator). As the rotor turns one-half turn, the polarity of the windings reverses. This continuous change of winding polarity creates alternating current.

acceleration sensor: Sensor that provides acceleration data to the computer in an electronic suspension system.

acceleration test: See *ignition load test.*

accelerator pedal sensor: Sensor that feeds an electric signal to the ECM that corresponds to pedal position.

accelerometer: An inertia sensor, sometimes mounted in a vehicle's air bag, that measures changes in motion or deceleration.

accessory system: Systems that are not vital to a vehicle's operation, including the air conditioner, sound system, power seats, and rear window defogger.

accident: See *vehicle collision.*

accumulator: Device that is used in the apply circuit of a band or clutch in an automatic transmission to dampen hydraulic pressure surges by temporarily absorbing some pressure. *Also,* a receiver-drier combination used to remove moisture and store additional refrigerant in a vehicle A/C system.

acid-core solder: A type of solder that has an internal core of acid flux. This type of solder is not to be used for electrical repairs.

active restraint system: A restraint system that requires the occupants to ready the system. For example, seat belts that must be buckled manually are classified as an active system.

active sensor: Computer sensor that generates its own voltage signal in response to a change in a condition.

active suspension system: A suspension system that uses computer-controlled hydraulic rams instead of conventional suspension system springs and shock absorbers. The hydraulic rams support the weight of the car and also react to the road surface and different driving conditions.

actuator: Type of motor that converts an electronic signal into movement or motion.

actuator diagnostic test: Test that enables a technician to check if actuators are working. It uses a scan tool to order a vehicle's computer to energize specific output devices with the engine on or off.

adapter: On a scan tool, an adapter is a connector that allows the scan tool connector to fit a vehicle's data link connector if pin configurations differ.

adaptive cruise control system: Type of cruise control system that can alter vehicle speed automatically when approaching another vehicle too quickly from behind.

adaptive strategy: Feature in an ECM that allows it to adjust its operation to compensate for sensor, actuator, or vehicle deterioration.

addition: Arithmetic process of combining two or more numbers to find the total quantity.

adhesive: High-strength glue used for holding parts and other automotive items together.

adjustable shock absorber: Shock absorber that has a means of changing shock stiffness, either manually with an adjustment knob or automatically with a computer.

adjustable wrench: Wrench with movable jaws for fitting different size bolt and nut heads. It is also called a Crescent wrench.

adjusting nut: A nut on a worm-type steering gearbox that is used to set worm shaft bearing preload.

adjusting screw: A screw on a worm-type steering gearbox that is used to set the sector shaft clearance.

aerodynamics: Study of the motion of air as it interacts with a moving object. Aerodynamics is a major concern for automotive designers when creating a vehicle body.

after-running: See *dieseling.*

afterburner: On a catalytic converter, an afterburner is a device that reheats or re-burns exhaust fumes.

AGM battery: See *absorbed glass mat battery.*

air bag: A strong, reinforced nylon sack attached to the metal frame of the air bag module. It is tightly folded for storage in the steering wheel pad, the dash, the door panel, or the side of the seat.

air bag control ECM: See *air bag controller.*

air bag controller: Uses inputs from the impact and safing sensors to determine if air bag deployment is needed. It is also called an air bag control ECM.

air bag igniter: Air bag module component that generates a small electric arc when an electrical signal is sent to it from the air bag controller. Its flash causes a huge volume of expanding gas.

air bag module: A nylon bag and an igniter-inflator unit enclosed in a metal and plastic housing.

air bag powder: A powder, usually sodium hydroxide, that may blow out of the air bag on deployment.

air bag sensor: Inertia sensor that signals the control ECM in the event of a collision by detecting a rapid change in speed or velocity.

air bag system: A protective device that deploys inflatable nylon bags to help protect a vehicle's occupants during a collision.

air bag vent hole: Small hole around the air bag that allows for rapid deflation of the air bag after deployment.

air blowgun: Handheld tool that attaches to a compressed air system to blow off small bits of dirt, solvent, water, and other debris and to blow out bolt holes, coolant passages, and oil passages.

air chisel: See *air hammer.*

air chuck: Pressurized air hose attachment designed to depress the pin of a tire valve core with the purpose of opening the valve for tire inflation or deflation.

air cleaner: See *air filter.*

air cleaner carbon element: Air filter that may be used to absorb fuel vapors when an engine is shut off.

air compressor: A pump that forces air, under pressure, into a storage tank.

air conditioning compressor: A refrigerant pump, bolted to the front of the engine, that pressurizes refrigerant and forces it through the cooling system.

air conditioning condenser: A radiator-like device that transfers heat from the refrigerant to the outside air.

air conditioning system: Set of components that lowers passenger compartment temperature and humidity. It is combined with the heating system.

Copyright Goodheart-Willcox Co., Inc.

air cooling system: Circulation of airflow over the cooling fins on engine cylinders to remove heat from the cylinders and prevent overheating.
air distribution manifold: Part of an air injection system that directs a stream of air toward each engine exhaust valve.
air dome: A hump formed in the top of a fuel tank as part of a vehicle EVAP system to allow for fuel expansion and tank filling without spillage.
air drill: Compressed-air tool with a tool attachment at the tip. Power output and speed adjustment capabilities make it a versatile tool. With specific attachments, air drills can drill holes, grind, polish, and clean parts.
air filter: Vehicle part that removes foreign matter (dirt and dust) from the air entering the engine intake manifold. It is also called an air cleaner.
air gap: Clearance that separates the wheel speed sensor tip from the spinning teeth of the sensor rotor.
air hammer: Compressed-air tool featuring different cutting and hammering attachments that are very rapidly struck against a part or surface. It is also called air chisel.
air hose: A flexible, high-pressure hose that carries a source of air pressure for tools and equipment throughout an automotive shop.
air induction system: Subsystem of an electronic vehicle fuel injection system. It filters, routes, and controls outside air flowing into engine cylinders.
air injection pump: Low-pressure pump driven by an engine and used to force air into an exhaust manifold.
air injection system: A method of reducing hydrocarbons and carbon monoxide emissions by forcing fresh air into the exhaust ports of an engine by means of an air pump. It is also called an Air Injection Reaction system or AIR.
air jet combustion chamber: Combustion chamber designed with a small, extra valve that allows a stream of air to enter the combustion chamber to aid swirl and combustion efficiency.
air ratchet: A special compressed-air wrench with limited turning power designed for working in tight spaces.
air shock: Shock absorber that uses air pressure, rather than springs, to maintain vehicle height.
air spring: Air-filled rubber cylinder that is lighter than an equivalent coil spring; can provide a smoother ride compared to a coil.
air supply system: Subsystem of a vehicle fuel system. It allows clean, filtered air to flow into the engine's combustion chambers.
air test: Test that forces pressurized air through transmission passages to detect leaks, stuck parts, or blocked passages.
air tool: Tool that uses compressed air for operation.
air wrench: See *impact wrench*.
air-fuel ratio: Ratio by weight between the air and fuel that makes up an engine's fuel charge.
airflow sensor: Sensor measuring the quantity of air entering an engine.
alcohol: Clean-burning alternative automotive fuel that is not widely used outside of the racing industry due to its high expense to use and produce.
alignment: Term for the positioning of an object in a straight line.
alignment equipment software: Software that contains computer instructions, information for using the alignment equipment, alignment specifications for various makes and models of vehicles, and other helpful information.
alignment head: Part of a wheel alignment machine that mounts on the vehicle wheels and is used to check caster, camber, and toe.
alignment machine: Machine used to correctly align a vehicle's wheels. Consists of the rack, console, and related parts.
alignment rack: Fixture onto which the vehicle is driven for alignment measurement and adjustment.
Allen wrench: A hexagonal wrench, usually "L" shaped, designed to fit into a hexagonal hole.
all-wheel drive system: Type of drive system that transmits power to all four wheels at all times. A special internal clutch in the transfer case diverts more or less power to the front wheels depending on road conditions.
all-wheel drive train: Configuration with the engine in the front and twin differentials to distribute engine/electric power to all four wheels and tires.
alphanumeric: A system that uses letters and numbers to denote tire characteristics and limits.
alternate power source: A method of producing energy, other than gasoline and diesel oil, to propel a motor vehicle.
alternating current (ac): An electrical current that moves in one direction and then the other.
alternative fuel: Term used to categorize any vehicle fuel other than gasoline and diesel fuel. Some examples are alcohol, methane gas, and hydrogen.
alternator: An ac generator that uses mechanical (engine) power to produce electricity.
alternator bearing: Grease-packed bearing used to produce a low-friction surface to support the rotor shaft as the shaft spins inside the stator and alternator housing.
alternator brush: Brush that feeds battery current into the slip rings by means of creating a sliding electrical connection with them.
alternator drive belt: Belt that links the engine crankshaft pulley with the alternator pulley to power the alternator.
alternator fan: Fan mounted on the front of the rotor shaft that draws air through and over the alternator to prevent overheating.
alternator pulley: Circular, grooved disk attached to the front of the rotor shaft providing a means of spinning the rotor using a belt.
alternator rectifier: An assembly that uses diodes to convert stator current (alternating current) to direct current through full-wave rectification. It is also called a diode assembly.
alternator rotor assembly: Consists of two claw-shaped pole pieces surrounding field coil windings, all mounted on the rotor shaft. Opposing north/south poles on each claw produce an alternating current as the rotor spins.
alternator slip ring: Ring mounted on the rotor shaft that connects each end of the rotor's field windings to provide dc current.
alternator stator: Produces the electrical current of the alternator with three sets of windings wrapped around a laminated iron core. The windings connect to the rectifier.
alternator warning light: Light wired to the charging system that glows when alternator output falls to a certain level.
aluminum cylinder block: Engine block used in many late-model vehicles due to its lighter weight, ability to increase fuel economy, and better heat dissipation properties than a cast iron block.
AM radio: Radio designed to pick up radio signals that vary in amplitude (strength). It operates on a frequency of 530 to 1610 kilohertz (kHz).
ambient temperature switch: Temperature sensitive switch that is designed to prevent air conditioner operation when outdoor temperatures are below a set point.
American Wire Gage (AWG) system: A system used to indicate the diameter of conductors. A smaller number, or wire gage, denotes a larger conductor diameter, and vice versa.
ammeter: Instrument used to measure the flow of electric current in a circuit in amperes. It is normally connected in series in a circuit.
ammeter indicator: Instrument cluster display that measures current output of the alternator.
ampere: The unit of measurement for the flow of electric current.
amp-hour rating: Measurement of how much current a battery can produce for 20 hours at 80°F (27°C) with battery voltage staying above 10.5 volts.
amplitude: Measure between the highest part of a waveform and the lowest part of a waveform, which can be negative.
analog instrument: Instrument that uses rotating needles or dials to indicate vehicle operating conditions.
analog multimeter: Multimeter that uses a needle or pointer to show electrical readings. In addition to measuring constant values, it can detect changes in voltage, current, or resistance.
analog scope pattern: Oscilloscope readout that has a smooth, gradual change in voltage over time.
analog signal: A signal that can have a continuous range of strengths.
antenna: Device that picks up a broadcast signal and feeds it through the antenna lead to the radio. Some antennas are a very fine piece of wire in the windshield glass. Other antennas are a metal mast (rod) mounted in the car body.

Copyright Goodheart-Willcox Co., Inc.

antifreeze: A liquid, usually ethylene or propylene glycol, that is added to water in a vehicle's cooling system. This mixture serves as the engine's coolant.

antifriction bearing: A bearing that uses balls or rollers between a journal and bearing surface to decrease friction.

antiknock additive: Extra chemical added to gasoline that slows down the burning of gasoline to prevent engine ping, or knock.

anti-lock brake system (ABS): A computer-controlled system that is part of the base brake system. The system cycles the brakes on and off to prevent wheel lockup and skidding.

anti-rattle clip: Clip that snaps onto a brake pad to keep it from vibrating and rattling.

armature: The core and shaft of an electric motor or alternator, consisting of electromagnets (known as field coils) and contacts (known as the commutator). As the armature rotates, the field coils change polarity to keep it rotating.

armature core: Indented iron piece within the starter armature that holds the windings in place. Iron is used to strengthen the magnetic field produced by the windings.

armature motor shaft: Pole that extends the length of the starter armature supporting the spinning armature on one end and the starter pinion gear/pinion drive unit on the other.

arming sensor: See *safing sensor.*

ASE-certified automobile technician: Technician who has passed a specific ASE test and completed the work requirement to achieve ASE-certification in that automotive area.

ASE-certified master automobile technician: Title awarded to a technician who has passed all the ASE Automobile & Light Truck Certification Tests (A1-A8, A9 is not required) and completed the work requirement.

aspect ratio: The ratio between tire section height and section width.

asphyxiation: A condition in which the body is deprived of oxygen, which can result in dead tissue, unconsciousness, and death.

aspirator valve: Type of valve that allows air or liquid flow in only one direction, opening and closing based on pressure pulses. It is also known as a check, gulp, or reed valve.

assembly: A set of fitted parts designed to complete a specific function.

assembly line diagnostic link (ALDL): See *data link connector (DLC).*

assist hybrid: See *mild hybrid.*

asymmetric tire: Type of tire that has a different tread pattern on its inner edge than its outer edge. The outer tread pattern is designed to improve cornering on dry surfaces, while the inner tread pattern is designed to improve traction on wet surfaces.

atmospheric engine: See *normally aspirated engine.*

atmospheric pressure: Pressure formed by the air surrounding Earth. At sea level, the atmosphere exerts 14.7 psi (103 kPa) of pressure on everything.

atmospheric suspended brake booster: This system has atmospheric pressure on both sides of the diaphragm or piston when the brake pedal is released. As the brakes are applied, a vacuum is formed on one side of the booster. Atmospheric pressure then pushes on and moves the piston or diaphragm.

atom: A microscopic particle that cannot be broken into smaller pieces without losing its properties.

attitude: Height ratio between the front and rear of a vehicle's body.

auto parts specialist: An individual with a general knowledge of the components and systems of a vehicle, and is capable of using auto industry tools to quickly and accurately find needed parts.

auto ranging: Feature of a digital multimeter that automatically changes to the correct range. All that has to be set on the meter is the knob for volts, amps, or ohms.

auto salesperson: A professional who promotes automobiles or automotive parts and equipment in an attempt to sell said products.

automated manual transmission: Transmission that uses computer control and sensors to allow shifting gears without clutch pedal disengagement. Computer control synchronizes the speed of the engine with the transmission so that no load is sent through the transmission while shifting.

automatic clutch adjuster: A quadrant and pawl device attached to the top of a clutch pedal. When the clutch is depressed, the pawl locks on a certain tooth of the quadrant to eliminate play from the clutch cable.

automatic engine clutch: Assembly that uses computer control and several control modules to operate a conventional clutch or a set of wet clutches.

automatic headlight dimmer system: System that uses a light sensor, amplifier, and relay to control the high and low beam headlights.

automatic locking hub: Type of locking hub in a four-wheel-drive vehicle that electrically locks the hubs at the front wheels to the front axles when the driver shifts into four-wheel drive.

automatic manual clutch: Type of manual transmission that uses driver-operated shift buttons and a computer to electronically control manually shifting gears.

automatic parking system: System that uses computer control with proximity sensors and/or vehicle cameras to back up, steer, and brake a car into a parallel parking space.

automatic suspension leveling system: Suspension system that uses air shocks or air springs, height sensors, and a compressor to maintain curb height. Changes in vehicle load are counteracted with an automatic increase/decrease in suspension air pressure.

automatic temperature control system: System that uses various pressure and temperature sensors and a control module (computer) to maintain a preset passenger compartment temperature.

automatic transaxle: A combination of an automatic transmission and a differential in a front-wheel-drive vehicle. It consists of a torque converter, an oil pump, a valve body, pistons and servos, bands and clutches, planetary gearsets, and differential.

automatic transmission: A transmission that uses fluid pressure to shift itself. Shift points and range are determined by road speed, engine loading, altitude, and throttle position. Late-model automatic transmissions are computer-controlled.

automatic transmission fluid (ATF): Mineral oil with special additives to make it compatible with clutch and band materials and to prevent foaming and breakdown.

automatic transmission slippage: Slight to severe problem that occurs when the gearsets within a transmission engage only partially, causing the vehicle to hesitate during shifts.

automobile: Term derived from the Greek word "autos," which means self, and the French word "mobile," which means moving. Modern "self-moving" vehicles combine engineering and technology in a safe, reliable means of transportation.

automotive brake: Mechanism that provides a means of using friction to either slow, stop, or hold the wheels of a vehicle.

automotive clutch: Assembly of discs and other parts that is used to connect and disconnect an engine from a manual transmission or transaxle.

automotive designer: An individual with strong artistic abilities and engineering knowledge who can imagine and create sketches or models of new body and part designs.

automotive engineer: A highly paid, college-trained individual who uses math, physics, and other advanced technologies to design new and improved automobiles, automotive systems, and parts. A complete working knowledge of automobiles is required.

automotive instructor: An experienced technician capable of sharing his/her knowledge effectively to students. Most instructors are also required to have a college degree.

automotive technician: Individual with the skills to diagnose, service, and repair automobiles for a living.

auto-off headlamp system: System that automatically turns the headlamps off after a short delay period, once the engine is turned off.

auxiliary audio input: Terminal that allows a digital audio player to be connected to the vehicle's stereo system.

auxiliary chain: Chain powering additional vehicle components; driven by an extra sprocket, usually located in front of the crankshaft timing chain sprocket.

axle end play: Lengthwise movement of a drive axle that should meet specifications to avoid mechanical problems.

axle gear: Side gear in a differential that transfers motion to the drive axles.

axle housing: A metal enclosure for drive axles and differential. It is partially filled

Copyright Goodheart-Willcox Co., Inc.

with differential fluid and other additives as needed.

axle locknut: See *hub locknut.*

axle retainer plate: Metal plate that bolts to the outside of the axle tube to hold the axle and axle bearing to the axle tube.

axle shaft: Shaft or shafts used to transmit driving force to the wheels of a vehicle.

axle shim: Flat, metal ring or plate placed between the axle retainer plate and axle housing to adjust the bearing preload to control axle end play.

axle washer: Special washer installed between a wheel driving hub and hub locknut.

B

backfiring: Condition caused by unburned air-fuel mixture igniting in the intake manifold or exhaust system. A loud bang or pop sound can be heard when the mixture ignites.

backup light switch: Electric switch that closes the circuit to illuminate the reverse lamps when initiated by the reverse gear shift linkage, solenoid, or servo.

balanced valve: See *shift valve.*

balancer shaft: One or more offset shafts geared to either the crankshaft or camshaft, used to counterbalance crankshaft vibration. Also called a silent shaft.

balancing coil gauge: Type of dash gauge that uses two electric coils to cause needle deflection.

ball-and-trunnion joint: A type of constant velocity universal joint that has ball bearings situated on a trunnion pin that fits through a hole on the drive shaft. Springs hold the shaft centered and the balls allow, but limit, shaft movement.

ballast: Transformer used in high energy discharge lightbulbs.

ball bearing (antifriction): A bearing consisting of an inner and outer hardened steel race separated by a series of hardened steel balls.

ball guide: Channels that route extra ball bearings in and out from between the worm and ball nut in a recirculating-ball gearbox.

ball joint: A flexible joint with a ball and socket-type construction. It is used primarily in steering linkage and steering knuckle pivot support. The ball joint is designed to allow the suspension to move up and down while allowing the steering knuckle to turn.

ball joint separator: Puller tool used to pry a ball joint from a steering knuckle.

ball joint wear indicator: Device on a ball joint that recesses into the joint to display the amount/degree of wear on the joint.

ball nut: Grooved nut that rides on the ball bearings and the worm gear in a recirculating-ball gearbox. The moving ball bearings force the nut up and down the worm gear without turning.

ball peen hammer: Type of hammer with a flat face for general striking and a round end for shaping metal parts.

band: Holding member with a friction material coating in an automatic transmission. It is used to stop clutch rotation in certain transmission gear ranges.

band adjustment: Process of tightening an adjustment screw to specifications when setting the clearance between a band and clutch drum in an automatic transmission.

band adjustment screw: Screw used to change clearance between the band and clutch drum in an automatic transmission.

band and clutch: Devices that use clamping pressure to apply planetary gears in an automatic transmission/transaxle. Different bands and clutches can be activated to operate different units in gearsets.

bare cylinder head: A machined cylinder head casting without any parts installed.

barrel: Small cylinder that holds a plunger of an inline diesel injection pump.

base line: The reference line, or zero volts on an oscilloscope display.

base voltage: Battery voltage with the engine off.

basic circuit problem: Circuit trouble that increases or decreases current, resistance, or voltage within the circuit.

basic refrigeration cycle: The refrigerant goes through four phases: compression, condensation, expansion, and vaporization.

battery: Source of electrical energy within a vehicle.

battery acid: See *electrolyte.*

battery bank: See *HV battery.*

battery cable connection test: Test that uses a voltmeter to check for high resistance between a battery cable end connector and a battery post.

battery cables: Wires, usually #10 gage to #1 gage copper conductor with plastic insulation and metal terminals, that connect the battery terminals to the vehicle's electrical system.

battery cap: Plastic piece that snaps into the hole above each battery cell to prevent electrolyte from spilling out of a battery and gases inside a battery from igniting.

battery carrier: Adjustable handheld clamp that tightens two forceps across the width of a battery allowing for easy removal from the battery tray.

battery case: High-quality plastic housing divided into compartments that hold the battery elements and electrolyte. It is designed to handle extreme conditions and corrosive elements.

battery cell: Battery division made up of a negative and positive plate, container, and electrolyte. An HV battery uses an acidic lithium paste or gel, while a lead-acid battery uses liquid sulfuric acid as an electrolyte.

battery charge indicator: Device designed into the battery cover that provides a visible sign of the general charge condition of the battery. It is also called a battery eye or test indicator.

battery charger: Machine that forces current back through a battery to restore the charge on the cell plates and reenergize it from a discharged state.

battery cover: Plastic piece that is bonded to the top of the battery case to seal it.

battery cycling: Amount of time between the discharging and charging of battery cells.

battery drain test: Test designed to check for an abnormal current draw (high parasitic load) that is discharging a battery while the ignition key is off.

battery eye: See *battery charge indicator.*

battery heat shield: Cover or plate that fits over the battery or between the engine and battery to protect it from excess engine heat.

battery hold-down: See *retainer.*

battery leakage test: Test designed to determine if electrical energy is draining and discharging across the top of a battery case. A dirty battery top can cause leakage.

battery load test: Test that places a battery under full-current load to measure the current and voltage output and the overall performance of the cells.

battery pack fuse: Fuse that will burn open to isolate a failed battery pack from the rest of the battery if current flow is too high.

battery pack voltage: Between 7.2–9.2 volts, depending on the number and types of battery cells.

battery pack warning light: A light in a hybrid vehicle instrument cluster that illuminates if the HV battery pack's state of charge is below normal limits or for other mild battery problems.

battery plate: Stiff mesh framework each grouped in a battery cell and coated with porous lead that allows penetration of electrolyte to aid the chemical reaction of electricity production within the battery.

battery post: Round metal terminal that protrudes from the battery cover and serve as male connections for the female battery cable ends.

battery service life: The acceptable period of use in service of a battery. A 12-volt battery is 3-5 years. An HV battery is more dependable and can last an average of about 150,000 miles.

battery stack: See *HV battery.*

battery strap(s): Band with two ends that attach to opposite battery terminals creating a handle to lift and carry a battery. *Also,* within a 12-volt battery, lead bars that connect the positive and negative battery plates into similar groups. They are also called connectors.

battery temperature sensor: Sensor found in many late-model vehicles that monitors battery temperature, providing the ECU with data on when to vary the battery charging rate.

battery terminal: Two top post or two side links that provide a means of connecting the battery plates to the vehicle's electrical system.

battery terminal test: Test that checks for a poor electrical connection (high voltage drop) between the battery cables and battery terminals on post-type batteries.

battery thermistor: Device mounted on the positive battery cable that rests against the battery to measure its temperature. It allows the charging system to alter charging output, as needed.

Copyright Goodheart-Willcox Co., Inc.

battery tray: Plate on which the battery sits, usually found in the engine compartment. The retainer fastens to the tray to help securely hold the battery in place.

battery voltage test: Test to determine battery condition and general state of charge by measuring static battery voltage.

bead: The steel-reinforced edge of a tire that engages the wheel rim.

bead breaker: Pneumatic arm tool and bar on a tire changing machine that is used to force a tire bead away from or onto the wheel rim as the tire spins.

bearing crush: A split-type bearing is machined to sit slightly taller than its bore so both halves clamp against each other when bearing caps are tightened. It is used to help prevent a bearing from spinning inside its bore during engine operation.

bearing housing: Enclosure around the turbo shaft that contains bearings, seals, and oil passages.

bearing insert: A removable piece of metal that fits into the main bearing bores.

bearing locating lug: A small flange on a split-type engine bearing used to position the bearing in its bore. The lug fits into a recess machined in the bore or cap.

bearing oil hole: Hole in engine bearings that allows oil flow through an engine block to a clearance between a bearing and a journal.

bearing packer: Handheld tool designed to properly fill a bearing cage with grease.

bearing spread: The difference in the distance across the parting line of a split-type bearing compared to that of the bearing bore. This provides alignment and support after assembly as well as helps a bearing insert stick in its bore during assembly.

bearing support: Suspension part that holds the wheel bearings, axle stub shaft, and hub.

bell housing: See *clutch housing.*

bellcrank: Part in a clutch linkage mechanism designed to convert clutch pedal downward motion into a pulling motion for the release rod and clutch fork.

belt: Tire component installed between the tread and body plies. It strengthens the body plies and stiffens the tread. Belts can be made of various materials, including steel, nylon, rayon, polyester, aramid, Kevlar, or fiberglass.

belt-driven oil pump: Type of pump used with dry sump lubrication systems. Oil pump is driven by the crankshaft or off another accessory pulley that is driven by the crankshaft.

belt retractor: Device that takes the slack out of the seat belt so the belt fits snugly around the body.

belt squeal: Loud screeching or squeaking noise made by a slipping or worn vehicle belt.

belt tension gauge: Tool used to measure the tightness, or tension, of different vehicle belts after installation.

belt tensioner: Spring-loaded or hydraulic pulley that is used to keep tension and adjustment on serpentine belts.

belted bias tire: Tire construction method using crisscrossed plies with additional belts under the tread area.

bench bleeding: Removes air from inside the master cylinder. This must be done before installing the unit on the vehicle.

bench grinder: Bench-mounted machine with two wheels (an abrasive grinding wheel and a soft wire wheel) used for grinding, cleaning, or polishing operations.

bias ply tire: Tire construction method in which the plies run at an angle from bead to bead, with the angle reversed from ply to ply.

bimetal gauge: Type of dash gauge that uses two dissimilar types of metal bonded together to cause gauge needle deflection.

binary numbering system: A number system that uses two numbers (0 and 1) arranged in different sequences to represent other numbers, letters, words, computer input data, computer output data, or a condition.

bio-based oil: Oils, especially vegetable-based motor oils, developed as more environmentally friendly lubricating products.

bipolar junction transistor (BJT): An electronic component that is made by joining three semiconductor materials. It can act as a switch for electronic signals or serve as a current amplifier.

black diesel smoke: Smoke that indicates an injection system problem, or low compression is keeping fuel from burning.

black engine smoke: Smoke caused by an extremely rich air-fuel mixture.

bleeder screw: Screw that allows air to be removed from a hydraulic brake system. When the screw is loosened, hydraulic pressure can be used to force fluid and air out of the system.

bleeding: Process of using a pressure bleeder or manually pressurizing/depressurizing a vehicle system to purge air bubbles and any fluid out of the system.

block and head tester: Test tool that determines if combustion gases are present in engine coolant. It is also called a block tester or combustion leak tester.

block boring: Machining process that uses a single-point cutting bit to enlarge the diameter of engine cylinders.

block diagram: A diagram that uses boxes and symbols to illustrate components and lines to represent wires and hoses. This type of diagram simplifies a system or circuit so you can easily understand how an area of the system operates and how major components interact.

block girdle: A one-piece cap that fits over the bottom of the engine block, securing the main bearings and holding any balancer shafts. It is also called the main bearing bedplate or unit main cap.

block heater: A heating device installed in place of one of the block's freeze plugs. It is used to heat an engine during cold weather.

block ring ridge: A small lip or metal ridge formed at the tops of cylinder walls where the rings do not wear away metal. It is a sign of cylinder wear.

block tester: See *block and head tester.*

blocking ring: Toothed brass or copper ring that acts as a clutch to speed up or slow down the mating gears to match the speed of the output shaft.

blowby: Oil vapors and other emissions that leak past piston rings into an engine crankcase or form in an engine bottom end from heating of oil.

blower: An electric motor and fan assembly that forces air through the evaporator and into the passenger compartment.

blower intercooler temperature: Must be kept cooler than the engine's operating temperature by the supercharger cooling system.

blowgun: Compressed-air tool used to blow off small bits of dirt, solvent, water, and other debris and to blow out bolt holes, coolant passages, and oil passages.

blowout: Term for the instantaneous rupture and air loss of a vehicle tire.

blue diesel smoke: Smoke that indicates engine oil is entering combustion chambers and being burned.

blue-gray engine smoke: Smoke this color indicates that engine oil is entering combustion chambers.

bob weight: Weight installed on a crankshaft during crankshaft balancing to replicate the reciprocating weight.

body: A steel, aluminum, fiberglass, plastic, or composite (carbon fiber) skin forming the outside of a vehicle.

body control area network (B-CAN): A group of computers that work together to operate relay modules, entry lights, exterior lights, the horn, interlocking system, key-in reminder, keyless entry, power door locks, seat belt reminder, security alarm, turn and hazard signals, wiper-washer system, and other functions. B-CAN communicates at a data rate of about 33 kbps (kilobits per second).

body dive: Term for a vehicle body that tilts down in the front, as during vehicle braking.

body-over-frame construction: Vehicle design in which the body is installed over the frame and held in place by large bolts. This design is still used on some large passenger cars, larger vans, pickup trucks, and sport utility vehicles.

body pillar: A metal beam that extends up from the bottom of the windshield to the roof panel.

body plies: Rubberized fabric and cords wrapped around the beads. They form the carcass, or body, of the tire.

body roll: Term for a vehicle body that leans to one side, as when turning a corner.

body squat: Term for a vehicle body that tilts down in the rear, as during vehicle acceleration.

bolt: An externally threaded rod with a head on one end.

bolt head marking: Markings of lines or numbers that specify the tensile strength of a bolt.

bolt tightening sequence: The order in which a set of fasteners on a part must be tightened to prevent leaks, warping, or other problems from uneven tightening. It is also called torque pattern.

Copyright Goodheart-Willcox Co., Inc.

boost charger: See *fast charger.*
boost pressure: Increased intake air pressure provided by a supercharger or turbocharger to an engine. Most production superchargers and turbochargers provide a boost pressure of 4–10 psi (30–70 kPa) above atmospheric pressure inside the intake manifold plenum.
boot: Insulated cap that fits over each end of the secondary wires to protect the metal connectors from corrosion, oil, and moisture.
boring bar: A machine shop tool that cuts a thin layer of metal out of a worn engine cylinder to make it larger in diameter.
bottom dead center (BDC): The point of travel where a piston is at its lowest point in the cylinder.
bowl fuel filter: Type of fuel filter found in modern diesel engines that is shaped to trap water out of fuel.
brake accumulator: A chamber in an ABS modulator used for storing extra fluid under high pressure.
brake backing plate: Metal plate that holds the shoes, springs, wheel cylinder, and other parts inside the brake drum. It also helps keep road dirt and water off the brakes.
brake booster: A vacuum, electric, or power steering operated device that assists brake pedal application.
brake caliper: Disc brake component that forms the cylinder and houses the piston and brake pads. It produces the clamping action on the rotating disc to stop the vehicle.
brake disc: The brake disc uses friction from the brake pads to slow or stop wheel rotation. It is normally made of cast iron and is also called a rotor or brake rotor.
brake disc resurfacing: Refers to machining a disc's friction surfaces on a brake lathe. Disc resurfacing is needed to correct runout, thickness variation, or scoring.
brake disc runout: The amount of side-to-side movement measured near the outer edge of the disc's friction surface.
brake disc thickness: The thickness of the disc measured across the two friction surfaces in several locations.
brake drum: Brake drums provide a rubbing surface for the brake shoe linings.
brake drum grinding: Procedure to remove a high spot from the drum to true the friction surface.
brake drum resurfacing: Involves machining the friction surface of the drum on a brake lathe.
brake fluid: A specially blended hydraulic fluid used to transfer power and motion from the brake pedal to the wheel cylinders and brakes.
brake fluid level: Ideal amount of brake fluid contained in the master cylinder. It should be 1/4″ (6 mm) from the top of the master cylinder reservoir.
brake fluid pump and motor: A high-pressure pump operated by a small electric motor; it provides brake fluid pressure for an ABS system.
brake fluid reservoir: A container in an ABS modulator used for holding an extra supply of brake fluid.
brake horsepower (bhp): The usable horsepower delivered to an engine crankshaft.
brake hose: Hose that transfers fluid pressure from the master cylinder to the wheel brake assemblies.
brake inspection: Process of visually examining the brake pads and rotors with the tires removed from a vehicle.
brake light switch: Switch used to operate the brake lights, installed on the brake pedal linkage. It also signals the control module to shut off the cruise control when the brakes are applied.
brake light system: Lighting system commonly made up of a fuse, brake light switch, two rear lamps, and related wiring. The brake light switch is normally mounted on or near the brake pedal.
brake line: Metal tubing and rubber hose for transmitting pressure to wheel brake assemblies.
brake master cylinder-booster assembly: A conventional master cylinder with power assist for operating brakes under normal conditions.
brake pad: Friction unit that is pushed against the disc by the action of the master cylinder, caliper cylinder, and piston.
brake pad lining: Friction material surface that contacts the rotor or drum.
brake pedal assembly: A foot-operated lever for actuating the master cylinder and power booster.
brake pedal check: A fast and accurate way of checking many components of the brake system. This is done by applying the brake pedal and comparing its movement to factory recommended specifications.
brake pedal free play: The amount of pedal movement before the beginning of brake actuation.
brake pedal height: The distance from the pedal to the floor with the pedal fully released.
brake pedal reserve distance: The distance measured from the vehicle's floor to the brake pedal when the brakes are applied.
brake pedal switch: Switch that illuminates vehicle brake lights, disengages cruise control, and, in hybrid vehicles, starts regenerative braking.
brake pressure sensor: Measures the amount of hydraulic pressure produced by the driver pressing on the brake pedal.
brake pressure switch: A sensor that monitors brake fluid pressure and controls operation of the electric motor for the hydraulic pump.
brake rotor: See *brake disc.*
brake sensor: Sensor that monitors braking in an electronic suspension system. It can alter suspension stiffness to prevent body dive during hard braking.
brake shoe: Friction unit that is pushed against the rotating brake drum by the action of the hydraulic wheel cylinder.
brake shoe adjuster: Mechanism used to maintain the correct drum-to-lining clearance as the brake linings wear.
brake solenoid valve block: An electro-hydraulic device that contains coil-operated valves. The valves control brake fluid flow to each wheel brake cylinder.
brake system: A collection of components that work together to stop a vehicle.
brake system bleeding: Involves the use of fluid pressure to force air out of the brake line connections or wheel cylinder bleeder screws.
brake system flushing: Pressure bleeding all the old brake fluid out of the system.
brake vibration: Shows up as a chatter, pulsation, or shake problem only when the brake pedal is pressed.
brake warning light: Red warning light used to inform driver of a brake problem or that the parking brake has been applied. It typically indicates either an internal leak (master cylinder) or an external leak (brake line, hose, wheel cylinder) in the hydraulic system.
brake warning light switch: Pressure-sensitive switch that warns a driver of a pressure loss on one side of a hydraulic brake system. It is also called a pressure differential valve.
brake warning light system: A lighting system that informs the driver of a problem in the hydraulic brake system.
braking noise: Grinding sounds, squeaks, rattles, and other abnormal noises often can be used to trace the cause of a braking problem.
braking ratio: A comparison of the front wheel to rear wheel braking effort.
break-away torque: In a limited-slip differential, the amount of torque needed to make one axle rotate the clutches.
breakout box: Diagnostic tool with numbered test terminals that connect to an ECM connector or system wiring harness. A multimeter can then be used to check the appropriate terminals in order to measure circuit values.
British thermal unit (Btu): The unit of measurement for heat transfer from one object to another. It is equal to near 1055 joules.
broken-surface rod: Rough, irregular mating surfaces between a piston connecting rod and cap when the rod is scored and broken off during the manufacturing process. These surfaces match perfectly to prevent shifting during engine operation.
brush spring: Small spring that holds the alternator brushes in contact with the slip rings to allow current flow.
brushes: Copper pieces that slide on the commutator to carry battery current to the spinning winding.
bubble balancer: Type of tire balancer that static balances a wheel and tire assembly. After the wheel is mounted on the machine, weights are added to parts of the wheel to bring the bubble indicator to the balanced, center crosshair.
buffer: A device that can serve as a temporary storage area for data and prevent improper data from entering internal computer chips.
burn-off oven: See *heat-cleaning oven.*
burned transmission fluid: A black or dark brown-colored transmission fluid with a burned odor. It is commonly the result of slipping or overheating band and clutch friction material.

Copyright Goodheart-Willcox Co., Inc.

bus configuration: Computer network configuration in which several of the vehicle's computers are wired to a single conductor, or bus.
butt splice: A splice in which wires that are to be connected together are placed end-to-end, without overlap.
bypass circuit: Supplies direct battery voltage to the ignition system during starting motor operation.
bypass thermostat: Thermostat with an additional valve that blocks off the bypass for routing all the hot coolant through the radiator, not just most of the hot coolant.
bypass valve: Valve used to permit coolant flow when the thermostat is closed.

C

cable: Term referring to a wire with a large-diameter conductor. The outside diameter of a cable is generally much larger than that of a wire, and cables can contain one or more conductors.
calibration: In reference to measuring tools, involves adjusting the needles or digital readouts to measure accurately. Calibration procedures differ from tool to tool.
calibration gas: A test gas used to zero an exhaust gas analyzer's scales.
caliper: A brake assembly part that holds a hydraulic cylinder, piston, seals, and brake pads.
caliper cylinder: A machined hole in the caliper; the piston fits into the caliper cylinder.
cam-ground piston: A piston machined a few thousandths of an inch larger in diameter perpendicular to the piston pin centerline. This compensates for different rates of piston expansion due to heat and differences in metal wall thickness.
cam phaser hydraulic valve: Valve that reacts to electric solenoid action to redirect oil flow into and out of camshaft phaser(s).
camber: The inward or outward tilt of the wheel and tire assembly when viewed from the front of the vehicle.
camshaft: A shaft with offset lobes used to operate the valve train.
camshaft bearing: Insert pressed into the block or cylinder head; meant to reduce the friction of camshaft rotation. The camshaft journals ride in the cam bearings.
camshaft bearing clearance: The oil lubrication gap between a camshaft bearing and a camshaft journal.
camshaft bearing wear: Damage to camshaft bearings that can cause increased part clearance and may reduce engine oil pressure. It can be determined by measuring a bearing's inside diameter and subtracting this from specifications.
camshaft cover: An acoustically dampening lid over the top of a camshaft housing found on overhead camshaft engines.
camshaft drive: Mechanisms designed to smoothly transfer the rotational motion of a crankshaft to the camshaft(s) at one-half of engine speed. There are three types: timing gears, a timing chain and sprockets, or a timing belt and pulleys.
camshaft duration: Amount of time the valves stay open. It is determined by the shape of the cam lobe nose and flank.
camshaft end play: The front-to-rear movement of the camshaft in its bores.
camshaft grinding: Machine grinding done to restore camshaft lobe and journal dimensions to specifications.
camshaft housing: A casting mounted on top of a cylinder head to hold the engine camshaft(s) on overhead camshaft engines.
camshaft journal wear: Reduction in the size of the camshaft journal that results in increased part clearance and may reduce engine oil pressure.
camshaft lift: The distance a valve opens, calculated by subtracting the cam base diameter from the cam lobe height.
camshaft lobe: The offset, polished portion of a camshaft consisting of a nose, flank, heel, and base diameter. As the lobe turns on the camshaft, it imparts motion to other parts of a valve train.
camshaft lobe wear: Reduced lift or duration resulting from friction wearing off some of the camshaft lobe.
camshaft phaser: Replaces the fixed chain or belt sprocket with a hydraulic camshaft timing sprocket, or cam actuator. Each camshaft phaser uses high-engine oil pressure to rotate the camshaft in relation to its drive sprocket.
camshaft positioning tool: Tool used to hold dual-overhead camshafts in correct alignment during timing belt replacement or installation.
camshaft position sensor (CPS): A sensor used by a computer control system to reference camshaft position in order to adjust spark timing, fuel, etc.
camshaft position sensor indexing: Process during engine reassembly of installing the camshaft position sensor with the number one piston at TDC on the compression stroke. This base alignment will allow the sensor to correctly tell the vehicle ECM which cylinder is on its compression stroke.
camshaft service: Maintenance service that involves measuring camshaft lobe and journal wear, as well as measuring camshaft end play and bearing clearance.
camshaft solenoid: Solenoid that opens and closes phaser oil passages to retard or advance the camshafts in relation to crankshaft position.
camshaft straightness: A measure to determine if a camshaft is bent or warped.
camshaft thrust plate: Metal plate bolted to the front of a block or cylinder head to limit the front-to-rear movement, or end play, of a camshaft.
canister fuel filter: Type of fuel filter housed inside a metal container mounted on a fuel line.
canister vent solenoid: Electrically operated vacuum valve that replaces the fresh air vent used on older canisters.
cap screw: A bolt threaded into a part instead of a nut.
capacitor: An electrical component that absorbs voltage spikes by storing electrons, or electrical energy, thus protecting other vehicle electrical equipment.
carbon-core wire: See *secondary resistance wire.*
carbon monoxide (CO): A toxic by-product of partial burning of fuel. It is a deadly colorless, odorless gas.
Cardan universal joint: See *cross-and-roller joint.*
carrier bearing: See *case bearing.*
cartridge oil filter: Filter with a separate element that fits in an engine mounted housing.
case bearing: Bearing that fits between the outer ends of a differential case and the carrier. It is also called a carrier bearing.
case bearing preload: The force pushing differential case bearings together to eliminate excess play and clearance. Depending on the differential design, it can be adjusted by loosening or tightening an adjusting nut or using shims.
caster: Basically, the forward or rearward tilt of a steering knuckle (spindle support) when viewed from the side of the vehicle.
caster-camber gauge: Gauge used with the turning radius gauge to measure caster and camber in degrees.
casting number: Number formed into parts during manufacturing. They can be found on major components, such as an engine block and camshafts.
cast iron cylinder block: A heavy and strong engine block designed to withstand the high load forces found in high horsepower diesel and gasoline engines.
catalyst: Any substance that speeds a chemical reaction without itself being changed.
catalyst monitor: Name given to any oxygen sensor that is mounted after a catalytic converter. It is used in OBD II vehicles.
catalytic converter: An emissions control device that uses the elements platinum, palladium, and rhodium as catalysts to reduce harmful exhaust emissions.
catalytic converter temperature check: Test to quickly identify an inoperative converter catalyst by measuring the difference in exhaust temperature as it enters and leaves a catalytic converter.
C-clamp: Type of clamp with one clamping surface fixed at the end of a C-shaped body and the other at the end of an adjustable screw that passes through the clamp body to tighten.
C-clip type axle: Type of axle that uses a C-clip positioned in a groove on the axle shaft to hold the axle in place inside the differential assembly. This design is frequently used with an integral rear axle carrier.
cell voltage test: Test measuring the voltage of each cell designed to find if a battery is defective or just discharged.
center link: Steel bar used to connect the pitman arm to the tie-rods in a parallelogram steering system. It is also called a relay rod.
center support bearing: A bearing used to mount and support a two-piece Hotchkiss drive shaft.
center terminal (center electrode): The center terminal in a spark plug that conducts electricity into the combustion chamber.
centrifugal belt retractor: Part of a vehicle restraint system that uses centrifugal force to keep the seat belt from extending.

Copyright Goodheart-Willcox Co., Inc.

If you pull on the belt hard enough, the rapid centrifugal force engages the locking mechanism so the belt holds the driver or passenger in the seat.

ceramic insulator: Keeps the high voltage at the plug wire from shorting to ground before producing a spark in the engine cylinder.

cetane rating: Number given to diesel fuels that indicates the fuel's cold starting ability. The higher the number, the easier the engine will start and run in cold weather.

chain guide: Metal plates shaped to prevent chain slap on long lengths of chain. Guides have a metal body with a plastic, nylon, or Teflon face, allowing a chain to slide with minimum wear.

chain slap: Noise that occurs when a chain shakes because of excessive slack in the chain.

chain tensioner: Spring-loaded or hydraulic device that pushes on the unloaded side of a chain to keep it tight and remove excess slack in the chain.

channel: A single system of ABS sensor input and hydraulic output. There are a maximum of four channels, one for each wheel. One-, two-, and three-channel systems are also used.

charcoal canister: Metal or plastic canister filled with activated charcoal granules that absorb fuel vapors. It stores fuel vapors when the engine is not running.

charge indicator: One of three types of instrument cluster devices that informs the driver of the operating condition or output of the vehicle charging system.

charge voltage: Load voltage minus base voltage. This value should be at least 0.5 volts with the vehicle engine at warm idle.

charging: Current flowing back into battery cells from a charging system that can be stored until needed. This is a conversion of electrical energy into chemical energy by the battery.

charging system: System that consists of a battery, alternator, drive belt, voltage regulator, charge indicator, and charging harness. The job of the system is to reenergize the battery as the engine is running and provide electricity to the various vehicle electrical systems.

charging system analyzer: Electronic device that quickly measures charging system voltage to determine alternator operation.

charging system harness: Wiring setup electrically connecting the components of a vehicle charging system together.

charging system load test: Measures alternator/regulator current and voltage output under its maximum load.

charging system test: Test that quickly determines the operating condition of the charging system performed when symptoms point to low alternator current and voltage.

charging voltage: Alternator output voltage (13–15 volts) held by the regulator. Since this is higher than battery voltage (12.6 volts), current flows back into the battery and recharges it.

chassis: The framework of a vehicle without its body panels.

chassis dynamometer: A machine used to measure engine power at a vehicle's drive wheels.

chassis grease: An all-around vehicle body lubricant. It is applied on easy-to-reach vehicle hinges and latches.

chassis ground: A method of grounding a circuit that uses the metal part of a component to attach to ground.

chassis hertz: A numerical measurement of the stiffness of a vehicle's structure.

chassis stiffness: The amount of give or flexibility in a vehicle chassis. It is a primary factor affecting the quietness and smoothness of a vehicle's ride—the stiffer the chassis, the better.

chattering clutch: See *grabbing clutch*.

check valve: Valve that allows fluid to flow through it in only one direction.

chemical burn: A burn caused when a corrosive substance, such as solvents or battery acid, come into contact with skin.

chisel: A tool used for cutting off damaged or badly rusted fasteners and rivet heads. A hammer blow to the top of a chisel supplies the necessary force to remove such parts.

circuit: A source, resistance, and path to carry a flow from the source to the resistance and back to the source.

circuit breaker: Device that interrupts current if a circuit is overloaded or a short occurs. Unlike a fuse, it can be reset.

circuit resistance tests: Tests used to locate wiring problems in a charging system such as a loose connection, corroded terminal, partially burned wire, or other similar types of troubles.

circuit sensing: A system that uses a computer instead of dedicated sensors to monitor current flow through various components and circuits.

circular mil: Equals the area of a circle that has a 0.001 inch diameter.

classroom: Room within an automotive shop in which instructors teach students and other technicians the knowledge and skills needed to succeed in the automotive service industry.

cleaning tool: A tool, such as a scraper or a brush, used for removing carbon, rust, dirt, grease, old gaskets, and dried oil from parts.

closed cooling system: Type of cooling system that uses an overflow bottle and a radiator cap with pressure and vacuum valves.

closed loop: In reference to an electronic fuel injection system, information looping from the ECM, through the fuel system, into the exhaust system, and back to the ECM is used to determine efficient air-fuel mixture.

closed PCV system: Type of PCV system that uses a sealed oil filler cap, a sealed oil dipstick, ventilation hoses, and either a PCV valve or a flow restrictor to keep engine blowby from entering the atmosphere.

cloud point: Temperature at which paraffin (wax) separates out of diesel fuel. At this point, the paraffin can clog fuel filters and prevent diesel engine operation.

cluster gear: A cluster of gears that are all cut on one long gear blank. The cluster gears ride in the bottom of a manual transmission, providing a connection between the transmission input and output shaft.

cluster gear assembly: The input or output shaft gears in a manual transaxle transmission.

cluster gear shaft: See *countershaft*.

clutch: In a manual transmission, a friction disc assembly that engages and disengages the engine flywheel to transfer power through gearsets. In an automatic transmission, an assembly that uses a clamping pressure to transfer engine torque through the planetary gearset(s).

clutch adjustment: Process of setting the correct amount of free play in the type of clutch release mechanism designed in the clutch assembly.

clutch apply piston: Metal plunger that applies or releases pressure against the clutch discs within a clutch assembly.

clutch arm: See *clutch fork*.

clutch cable mechanism: Arrangement of cables inside a flexible housing that transfers motion from the clutch pedal to the clutch fork.

clutch cylinder: See *clutch drum* for automatic transmissions. See *clutch master cylinder* for manual transmissions/hydraulic clutch release mechanism.

clutch disc: Friction disc with an inner edge splined to the transmission input shaft. The face is held against or pulled away from the flywheel as the clutch operates and gears are shifted. It is also termed a friction disc.

clutch drum: Metal case that holds the clutch apply piston, pressure plate, discs, and other clutch assembly parts. It is also referred to as a clutch cylinder.

clutch fork: Lever that forces a release bearing into a pressure plate assembly for disengagement of the clutch. It is also called a release arm, clutch arm, or throw-out lever.

clutch housing: Cast iron or aluminum case that bolts to the rear of an engine to surround a flywheel and clutch mechanism. On hybrid vehicles, it may also house a motor-generator. It is sometimes called a bell housing.

clutch hub: Part of a multiple disc clutch assembly that meshes against the driving disc notches and fits inside the clutch drum.

clutch linkage mechanism: Arrangement of levers, rods, cables, or hydraulic lines that transfer motion from the clutch pedal to the clutch fork.

clutch master cylinder: Piston mounted in a sealed cylinder that produces the hydraulic pressure needed to operate the clutch. It is also called a clutch cylinder.

clutch pack: Set of friction discs and steel plates sandwiched together inside most types of limited-slip differentials.

clutch release mechanism: Mechanism that lets a driver operate a clutch in a manual transmission. It includes a clutch pedal assembly (mechanical linkage, a cable, or a hydraulic circuit), the clutch fork, and sometimes the release bearing.

Copyright Goodheart-Willcox Co., Inc.

clutch release spring: Spring that pushes the clutch discs apart during clutch disengagement.
clutch shaft: See *manual transmission input shaft.*
clutch shell: See *driving shell.*
clutch slippage: Problem that occurs when a clutch disc does not grip, or loosely grips, the flywheel and pressure plate. Instead of locking to transfer torque, the clutch disc slips against the flywheel and pressure plate.
clutch start switch: Switch that prevents current from reaching the starter solenoid to start an engine unless the clutch pedal is depressed (switch closed).
clutch switch: Switch in a cruise control system that signals the control module to deactivate the cruise control when the clutch pedal is depressed.
coaxial cable: A type of cable that has a center conductor surrounded by a metal shield with insulation separating the two. This keeps magnetic pulses from inducing unwanted voltage pulses. It is also called coax or shielded wire.
code history: A list of stored codes with the number of times each has occurred in a vehicle with onboard diagnostics.
coefficient of drag (Cd): Numerical value that represents the resistance of an object through air or water.
coil: An electrical component that consists of insulated wire wound into tightly-spaced loops to create an electromagnetic field. Coils are usually wrapped around an iron core to strengthen the electromagnetic properties. It is also called a choke or inductor.
coil oscillations section: See *intermediate section.*
coil pack: A device in the ignition system that consists of several ignition coils combined into one assembly. A coil pack is used in distributorless ignition systems.
coil pack ignition: An ignition system design that uses multiple ignition coils, a coil control unit, engine sensors, and a computer (engine control module) to operate the spark plugs.
coil spring: Length of spring steel rod wound into a spiral. Powerful coil springs are commonly used in vehicle suspension assemblies.
coil spring compressor: Screw-type tool used to compress coil springs during removal and installation.
coil spring pressure plate: Type of pressure plate that uses coil springs and release levers located behind the plate face to move the plate during clutch operation.
coil spring sensor: An air bag sensor that uses a small metal weight attached to a metal coil spring. The weight touches the sensor contacts and closes the circuit to the air bag controller.
cold cleaning tank: Tank used for removing oil and grease from parts. It is also called a cold-solvent tank.
cold cranking rating: Amount of current (in amperes) the battery can deliver for 30 seconds at 0°F (–18°C), while maintaining terminal voltage of 7.2 volts (1.2 volts per cell).
cold-solvent tank: Shop equipment made up of a pump, reservoir, and solvent. It is used to apply solvent to remove grease and oil from parts.
cold spark plug: A spark plug that has a short insulator tip and operates at a cooler temperature than a hot spark plug. It is used in engines operated at high speeds. The cooler tip helps prevent tip overheating and preignition.
cold-start fuel injector: Additional fuel injector used in some early indirect injection models that richens fuel mixture in an engine manifold to aid in starting a cold engine.
collapsible steering column: Type of steering column that crumples or slides together when forced forward during a collision to help prevent driver chest and face injury.
collision avoidance system: System that measures the distance between the front of a vehicle and any object in its path and automatically controls the braking and engine speed control systems to prevent an accident.
combination meter: Hybrid vehicle in-dash instrument cluster that contains a speedometer, odometer, and other vehicle gauges as well as the hybrid power display and drive ready light.
combination square: A tool with a sliding square mounted on a steel rule commonly used when a rule must be held precisely parallel to the item being measured.
combination valve: A single unit that functions as a brake warning light switch, a metering valve, and/or a proportioning valve in a brake system. *Also,* valve that combines both the expansion valve and the suction throttling valve into one assembly for controlling evaporator temperature in a vehicle A/C system.
combustion: Chemical reaction that occurs when a fuel is burned with an oxidant (oxygen).
combustion chamber: Area at the top of the cylinder where a spark plug ignites the compressed air-fuel mixture.
combustion efficiency: Measure of how well combustion consumes all the fuel's heat energy for maximum cylinder pressure and minimum exhaust by-products.
combustion leak test: Test that checks for the presence of combustion gases in engine coolant.
combustion leak tester: See *block and head tester.*
comeback: A repair that returns to be done over because the problem was not initially fixed.
commission: Pay system in which the technician obtains a set percentage of the flat rate charged to the customers.
commission plus parts: A variation of the commission pay system in which a technician being paid on commission also receives a small commission for the parts installed during a repair.
commutator: Segmented, sliding electrical connection between the armature windings and the brushes.
compact disc (CD) player: Device that plays music by reading plastic compact discs holding digitally stored music files.
compact spare tire: Type of vehicle spare tire that is smaller than the normal tire used on the vehicle. It is also referred to as a space saver spare.
compensating port: Releases extra pressure when the piston returns to the released position. Brake fluid can flow back into the reservoir through the compensating port.
component: See *part.*
component location chart: Diagram that shows the location of various parts on a vehicle. This type of chart is valuable for engine compartment repairs.
compound: A substance composed of molecules containing two or more elements.
compound planetary gearset: Gearset that combines two planetary units in a single housing or ring gear. It can have a second sun gear and can provide more gear ratios than a single planetary unit.
compression distance: The distance from the centerline of a piston pin hole to the top of the piston.
compression gauge: Pressure gauge used to measure the internal pressure developed by an engine cylinder on the compression stroke.
compression ignition engine: Type of internal combustion engine that squeezes air in the combustion chamber until it is hot enough to ignite the fuel. A diesel engine is an example of this type of engine.
compression limiter: Metal insert that allows enough bolt torque for proper sealing without deformation around bolt holes in plastic parts.
compression pressure: Amount of pressure produced in an engine cylinder on the compression stroke. It is measured in pounds per square inch (psi) or kilopascals (kPa).
compression ratio: The relationship of cylinder volumes with the piston at TDC and at BDC.
compression ring: The top set of piston rings designed to seal between the piston and cylinder to prevent escape of gases from the combustion chamber.
compression stroke: The portion of the piston's movement devoted to compressing the fuel mixture in the cylinder.
compression test: Method of testing engine cylinder(s) by determining how much compression pressure is developed. It is commonly performed any time symptoms point to cylinder pressure leakage.
compressor assembly: A motor-powered air pump that produces pressure for an electronic suspension system.
compressor cycling switch: One of two (thermostatic and pressure) cycling switches used in an expansion tube A/C system for operating the compressor to maintain correct evaporator temperature.
compressor housing: Part of the turbo housing that surrounds the compressor wheel. Its shape helps pump air into the engine.
compressor wheel: Driven fan that forces air into the engine intake manifold under pressure.
computer: A complex set of electrical circuits that, in an automobile, produce programmed electrical control currents for

Copyright Goodheart-Willcox Co., Inc.

actuators after receiving specific input signals from sensors.

computer-based service information: Service information stored or retrieved electronically using a personal computer. Data can be accessed quickly off a hard drive, computer network, CDs, DVDs, or via the Internet.

computer-controlled diesel system: System that uses a computer, sensors, and actuators to increase the efficiency of mechanical diesel injection.

computer control system: Subsystem of an electronic vehicle fuel injection system in which an ECM responds to sensor signals to control operation of a fuel injector and properly meter the precise amount of fuel into the engine.

computer network: Series of computers that each control specific systems, but communicate and work as one to improve overall vehicle efficiency.

computer signal: Electrical impulse or frequency used to carry electronic data.

computer system: Electric and electronic devices that control specific vehicle systems.

computer system block diagram: Simple service manual drawing that uses shapes (squares, rectangles) and lines to display the interaction of sensors, actuators, and a computer.

computer voltage regulator circuit: Circuit located in a power train control module that can precisely control the charging system by monitoring system output and reacting to changes in operating conditions.

computerized emission control system: System that uses various engine, exhaust, and fuel system sensors, a three-way catalytic converter, and dual-bank O_2 sensors to reduce pollution levels emitted from a vehicle.

concentricity: A measure of how closely two circular cross sections share a common axis. It is used to check the accuracy of valve seats after repair.

condensation: The changing of a gas (vapor) to a liquid.

conditioner: Device that changes signals for use by other chips and circuits in a computer. It can be used to transform an analog sensor signal into a digital signal that a computer would understand.

conduction: Heat transfer through objects that are touching each other.

conductor: Any material that allows the flow of free electrons. Metals (gold, silver, copper, aluminum, etc.) make good conductors.

cone clutch differential: Type of limited-slip differential that uses the friction produced by cone-shaped axle gears and centrifugal force to provide improved traction.

connecting rod: The connecting link between the crankshaft and the pistons.

connecting rod bearing: Inserts that fit into the connecting rods and rides on the crankshaft journals.

connecting rod bearing knock: A light, regular, rapping noise with the engine running at a constant speed above idle. It is caused by wear and excessive bearing-to-crankshaft clearance.

connecting rod number: Number marked or etched on each connecting rod to ensure its proper placement in an engine. They also ensure each rod cap is installed and orientated correctly on each rod body.

connecting rod side clearance: Distance between the side of a connecting rod and the cheek of the crankshaft journal or side of another rod.

connector: Plastic or rubber device with metal terminals or connection points for joining the ends of two or more wires. *Also,* see *battery strap(s).*

connector diagram: A diagram that shows the location of connectors and identifies each terminal in a connector. These diagrams are useful when trying to diagnose electrical problems.

console: Part of an alignment machine that typically consists of a color monitor, keypad, and computer, all mounted in a roll-around cabinet.

constant-ratio gearbox: Gearbox that uses the same gear reduction when steering from full left to full right.

constant velocity universal joint: Type of universal joint that normally has two cross-and-roller (Cardan) joints connected by a centering socket and center yoke. It is used in independent drive axle assemblies to allow the shafts to transfer torque through an angle smoothly. It is also called a double-Cardan joint.

contact cleaner: Chemical for cleaning deposits from contacts, switches, and other components.

continuity: A complete circuit path.

continuous fuel injection: Type of fuel injection in which injectors spray fuel whenever the engine is running.

continuously variable transmission/transaxle (CVT): Design of transmission/transaxle that uses a belt running between two variable-width pulleys to create an infinite number of driving ratios, rather than three, four, or five forward speeds.

control arm: Movable lever arm that forms part of a vehicle's suspension system. It fastens the steering knuckle to a vehicle's frame or body.

control arm bushing: Sleeve that connects the control arm to the frame and allows the control arm up-and-down movement on a shaft. The bushings are made of rubber that is tightly attached to inner and outer metal shells by a chemical and heat process.

control rack: Toothed rod inside a mechanical diesel injector pump that rotates the pump plunger to control the quantity of injected fuel. It is also called a control rod.

control sleeve: Collar through which a diesel injection pump plunger moves. It alters the amount of fuel pushed to each injector by controlling the length of the plunger's effective stroke.

control switch: Part of a cruise control system that signals the computer to maintain present vehicle speed.

control valve: Valve that controls the application of hydraulic pressure within a power piston in a power steering system.

controller area network (CAN): A high-speed computer data bus that can be used by several computers and sensors at the same time to communicate with each other.

convection: Heat transfer caused by the air surrounding objects.

conventional current theory: The theory that states that electrons flow through a circuit from positive (+) to negative (–). Electrons leave the positive terminal of the battery, flow through the circuit, and then re-enter the battery through the negative terminal.

conventional flow cooling: Type of engine cooling in which hot coolant flows from the cylinder head to the radiator.

conversion chart: A chart used to change a measurement value from one measuring system to another.

converter circuit: Portion of a hybrid power control module that can step dc voltage up or down.

converter pump: See *impeller.*

coolant heat storage system: System of components in a hybrid vehicle that house hot coolant after the engine is shut off or when the vehicle is in full electric propulsion. When the engine is started or demanded on, the stored, hot coolant is injected back into the engine to keep combustion efficiency high.

coolant strength: A measure of the concentration of antifreeze compared to the concentration of water. This ratio determines the freeze-up protection of the coolant.

coolant temperature sensor (CTS): A sensor that monitors engine coolant temperature. It is used by the engine control ECM to determine how much fuel is needed and when to enter closed loop operation.

coolant test strip: Product used to check coolant strength and pH level.

coolant voltage test: Test using a digital multimeter to measure voltage generated by antifreeze. This indicates the general age and condition of the antifreeze solution.

cooling fin: A series of thin metal strips placed between cooling passages to help dissipate heat.

cooling system: Radiator and other components that allow a coolant to circulate and maintain a constant engine operating temperature. Cooling systems are also necessary to control operating temperatures of an HV battery, motor-generator, or HV ECM circuit in hybrid/electric vehicles.

cooling system bleed screw: Screw provided to allow for removal of trapped air when refilling the cooling system.

cooling system diagnosis chart: Vehicle service manual chart showing which tests and repairs are needed for different cooling system problems, and their proper sequence.

cooling system fan: Fan that pulls air through the core of a radiator and over an engine to help remove heat. It increases the volume of air flowing through the radiator, especially at low vehicle speeds.

cooling system hydrometer: Tool used to measure the freezing point of the cooling system antifreeze solution. A coolant sample is pulled up into the clear scaled measuring reservoir and graded based on freezing point.

Copyright Goodheart-Willcox Co., Inc.

cooling system pressure test: Test that uses low air pressure forced into a sealed vehicle liquid-cooling system to locate leaks.
cooperativeness: The ability to work together with others to achieve a common goal.
cooperative training program: Program that allows a student to earn school credit and a wage by working in a commercial repair shop.
core plug: See *freeze plug.*
cotter pin: A metal pin that fits through a hole in a bolt, nut, or part to secure it.
counter gear: See *countershaft gear.*
countershaft: Shaft on which cluster gears are mounted. They transmit force from input gears to output gears. It is also termed a cluster gear shaft.
countershaft gear: A series of helical gears machined out of a single piece of steel. The largest gear on the countershaft gear is always the countershaft driven gear, which is the forward most gear. In addition to the driven gear, there is usually one gear on the gear cluster for each available reduction and overdrive ratio, plus a gear for reverse. It is also called a counter gear.
cracked cylinder head: Break in an engine cylinder head that results from engine overheating or physical damage from other broken parts. Usually, the crack happens at an exhaust seat or between chambers, allowing coolant or pressure leakage.
cradle: Segmented frame on a front-wheel-drive vehicle that supports the engine and front suspension.
crane boom: Extended neck of many engine hoists to which the lifting fixture is attached.
crankcase dilution: Excessive blowby or fuel in the vehicle engine oil.
cranking balance test: Test to find problematic engine cylinders that show a low compression pressure.
crankpin: Term for a machined and polished surface to which a piston connecting rod bolts. It is offset from and spins around the main crankshaft journal.
crankshaft: The main shaft that supports the connecting rods and turns piston reciprocation into motion.
crankshaft balancing: See *engine balancing.*
crankshaft-driven oil pump: An oil pump directly engaged to and powered by the crankshaft. The inner pumping element fits over and is keyed or locked to the crankshaft snout.
crankshaft end play: The forward and rearward movement of the crankshaft in its bore.
crankshaft front seal: Seal that keeps engine oil from leaking out between the crankshaft snout and the engine front cover.
crankshaft oil seal: Seal that prevents oil from leaking out of the front and rear of an engine.
crankshaft position sensor: Electronic sensor used to detect engine speed by monitoring the rotation of the crankshaft.
crankshaft pulley: Pulley that may be part of a harmonic balancer or bolted to the front of it. It operates belts for the alternator, water pump, air conditioning compressor, and other units.
crankshaft service: Service that includes cleaning the crankshaft, measuring journal wear, checking the crankshaft for straightness and cracks, and installing the crankshaft.
crankshaft sprocket: Sprocket keyed to a crankshaft snout. It transfers power through a timing chain to the camshaft sprocket.
crankshaft turning: Machining term for grinding the rod and main journals of a crankshaft smaller in diameter to fix journal wear or damage.
crankshaft vibration damper: Flywheel device attached to the front of a crankshaft that, due to its design, lessens the torque vibrations imparted on a crankshaft.
crash test: Test simulation where vehicles are crashed into stationary walls or other vehicles to measure how the vehicles and their occupants withstand and react to the impact forces.
crash test dummy: Inanimate human figure equipped with sensors used to measure the impact forces acting upon the human body during crash tests.
creeper: A padded board with wheels underneath that allows a technician to easily roll under and work on vehicles supported by jack stands.
crimp connector: A wire-splicing device that provides a quick way of joining wires or installing a terminal on a wire by crushing a metal lug around the wire conductor.
crimping pliers: Tool used to crush the metal part of a crimp connector around the wire connector.
crisscross pattern: A pattern of lines crossing one another back and forth. This pattern is used when tightening fasteners to give an even, gradual clamping force all along the part.
cross-and-roller joint: Type of universal joint that has bearing-capped yokes at right angles to each other, forming a cross shape when each shaft end is connected. It is also referred to as a Cardan universal joint.
crossbolted block: Design with cap screws inserted through the sides of a block and main bearing caps, in addition to the standard cap screws, for added strength.
crossflow radiator: Radiator design with cooling tubes running horizontally through the core and tanks on either side.
crossover pipe: Exhaust pipe that connects right and left header pipes together to equalize back pressure for a slight increase in engine power with natural aspiration.
crude oil: Oil mined directly out of the ground. It is used to make gasoline and diesel fuel, as well as many other products. It is also referred to as petroleum.
cruise control module: Part of a cruise control system that uses input signals to control outputs to throttle actuator.
cruise control system: System that uses a computer, sensors, and a throttle actuator to maintain vehicle speed for highway driving.
crush zone: Area on a vehicle located at the front and rear of the body-frame assembly that is designed to collapse during a severe impact.
cubic centimeter (cc): A metric unit commonly used to refer to engine displacement. One liter is equal to 1000 cubic centimeters.
cubic inch displacement (CID): A unit commonly used to refer to engine displacement. One cubic inch is roughly equal to 16.387 cubic centimeters.
cup: Rubber cup within the cylinder machined into a master cylinder assembly. It, along with the return spring and piston, builds pressure for a brake system.
cup expander: The ends of a wheel cylinder spring have metal expanders that help press the outer edges of the cups against the wall of the wheel cylinder when not pressurized.
curb height: Distance measured up from the level parking surface to a specific point on the unoccupied vehicle.
curb weight: The weight of an unoccupied vehicle with fuel, oil, and coolant filled, and all standard equipment installed.
curiosity: The eagerness and desire to attain knowledge and experience.
current: The rate of electron flow in a circuit.
current-limiting dwell: Dwell timing in which the engine control module sends a large amount of current through the ignition coil windings until a strong magnetic field develops around the windings.
cushioning spring: See *facing spring.*
customary measuring system: A system of measurement mainly used in the United States; originated from sizes taken from parts of the human body. For example, the width of a human thumb was used to standardize the inch.
customary rule: A straightedge scale that has numbered lines that represent full inches. Fractions of an inch (1/2″, 1/4″, 1/8″, and 1/16″) are shown with smaller, unnumbered lines.
cut point: See *emission standard base line.*
CV-joint boot: Flexible synthetic rubber balloon seal that keeps road dirt out of, and grease on, the bearings in a constant velocity joint.
CV-joint kit: Constant velocity joint replacement kit that contains a boot fitting and straps, new joint parts, and lubricating grease.
cybernetics: Study of how electrical and mechanical mechanisms can mimic the actions of the human body.
cycle: Term for the continuing formation of one complete positive curve and one negative curve illustrated by the voltage change in ac current.
cylinder: A hole or holes that have a set depth and contain pistons.
cylinder arrangement: The position of cylinders in the engine block in relation to the crankshaft.
cylinder balance test: See *engine power balance test.*
cylinder bore: Diameter of an engine cylinder, measured across the cylinder, parallel with the top of the block.

Copyright Goodheart-Willcox Co., Inc.

cylinder head: Metal section bolted on top of the engine block and forms part of the combustion chamber.
cylinder head milling: A machine shop operation where a thin layer of metal is cut or machined off the head gasket surface of a cylinder head.
cylinder honing: Machining process that provides a lightly roughened or textured surface on the smooth walls of a used cylinder. The process is also needed after cylinder boring to smooth rough cylinder walls. It is also called deglazing.
cylinder leakage test: Test that measures air leakage out of the engine combustion chamber to find mechanical problems.
cylinder number: Number that identifies the cylinders, pistons, and connecting rods of the engine. Normally, these numbers are stamped on the connecting rod or cast into the intake manifold.
cylinder out-of-round: Difference in cylinder diameter when measured front-to-rear and side-to-side in the block.
cylinder select: See *expanded display.*
cylinder sleeve: Metal, pipe-shaped insert that fits into a cylinder block to allow piston operation without cylinder block wear.
cylinder sleeving: Machining or boring an engine cylinder oversize and pressing in a cylinder liner.
cylinder taper: Difference in the diameter from the top to the bottom of a cylinder measured on the piston ring contact surface of the cylinder.

D

damper unit: A simple shock assembly that fits inside the coil spring on a strut assembly to prevent excessive jounce and rebound.
damping spring: See *torsion spring.*
data bus: Pathway for data inside a computer. It can also be used to refer to a circuit used to connect two on-board computers.
data link connector (DLC): Plug-in connector used to link the scan tool to a vehicle computer. It allows the scan tool to access vehicle computer data. It is also called a diagnostic connector or assembly line diagnostic link (ALDL).
datastream value: Voltage, degree, and other values that come to the ECM from sensors and actuators in the form of analog and digital signals.
daylight running lights: Type of headlight that turns on automatically whenever the ignition key is in the Run position.
dead axle: An axle that does not rotate, but merely forms a base onto which the hubs and wheels are attached.
dead battery: A fully discharged battery. This can be a common problem of 12-volt starting systems.
dead blow hammer: Type of hammer that has a plastic-coated, metal face filled with small metal balls called lead shot. The lead shot prevents a rebound when striking, and the coating prevents surface damage.
dead cylinder: Engine cylinder in which combustion is not occurring during the power stroke.
dead O_2 sensor: Term for an oxygen sensor that has little or no resistance or voltage output change when exhaust content changes.
dealership: A place of business that sells and services vehicles for a specific vehicle manufacturer.
decarbonizing cleaner: A very powerful chemical that can remove carbon, paint, gum, and most other deposits from parts.
decibel impact sensor: Air bag sensor that measures the amount of sound produced by a major collision.
decimal conversion chart: A chart used to quickly find equivalent values for fractions, decimals, and millimeters.
deck: A flat surface machined on the top of the block surrounding the cylinder heads.
decking: Process of surface milling cylinder head mounting surfaces until they are parallel and equidistant from the main bore. It is also referred to as squaring a block.
deck plate: Rigid metal cap bolted onto an engine block deck surface when power honing or boring to replicate the stress of an installed cylinder head. This prevents cylinder out-of-round or tapering when a cylinder head is torqued down.
deck warpage: Engine deck that is no longer flat or squared correctly. It often results from engine overheating, especially with thin-wall or aluminum blocks. A straightedge and feeler gauge on the head gasket sealing surface(s) of the block can measure the problem.
deep cycling: Allowing a battery to use 50–80% of its energy before charging.
DEFI amplifier: Device that boosts the voltage and current signal sent from an ECM to operate high-pressure direct fuel injectors.
DEFI fuel pressure regulator: Regulator controlled by the ECM that uses an electric solenoid to bypass excess fuel pressure back to the low pressure side of the system.
DEFI injector operating voltage: Usually higher than battery voltage, from 50–100 volts dc.
deglazing: See *cylinder honing.*
delivery valve: Spring-loaded valve in the outlet fittings to a diesel injection line that closes the injector nozzle quickly.
dependability: In relation to work performance, it is being a reliable employee, such as by reporting to work on time, not leaving early, or not taking too many days off.
desoldering bulb: Tool used to remove solder from an existing soldered joint. Once the solder is melted, the bulb is squeezed, placed near the molten solder, and released to suck the solder away from the joint.
deteriorated motor oil: Worn-out engine oil that contains hard, abrasive particles of carbon, steel, iron, ash, and other materials trapped inside the oil filter.
detonation: Severe combustion problem that results when unburned air-fuel mixture explodes violently in the cylinder.
Detroit locker: See *ratchet differential.*
diagnostic chart: Flowchart with diagrams and tables used in troubleshooting common vehicle system problems. Most diagnostic charts begin with a specific trouble code.
diagnostic connector: See *data link connector (DLC).*
diagnostic laptop computer: A laptop computer with automotive diagnostic software that combines the abilities of an advanced scan tool with dozens of test instruments to monitor, test, and record vehicle parameters, and to help technicians diagnose and repair vehicle problems based on online service information.
diagnostic tablet: A handheld, touch-screen computer that can retrieve and identify trouble codes, monitor vehicle performance, and perform tests remotely via an online network and a wireless sending unit that the technician plugs into the vehicle's DLC.
diagnostic trouble code (DTC): Digital signal produced and stored by a computer when an operating parameter is exceeded. It can be used to determine where a malfunction is located in a computer-controlled system.
diagonally split: Type of corner to corner brake system that has each master cylinder piston operating the brake assemblies on opposite corners of the vehicle.
dial indicator: Tool used to measure part movement or end play in thousandths of an inch or hundredths of a millimeter. Plunger movement of the tool is shown by a needle or digital display.
diaphragm spring: Steel spring disc positioned in the middle of a diaphragm pressure plate. Its segmented design aids in manual clutch operation.
diaphragm spring pressure plate: Type of pressure plate with a circular diaphragm spring cut into wedges mounted in the center of the plate. As pressure is applied to the center of the spring, the outer edges of the spring wedges push the plate to separate it from the clutch disc.
die: Tool for cutting threads on the outside of a rod or shaft.
dielectric grease: A special grease that blocks moisture and helps prevent corrosion without affecting electrical conduction.
diesel engine boost pressure: Allows a maximum turbocharger inlet air pressure of up to 20 psi (1.4 Bar).
diesel engine compression reading: Compression reading averages 275–400 psi (1900–2750 kPa), depending on the engine design and compression ratio.
diesel exhaust fluid (DEF): A mixture of urea and de-ionized water that is stored in a separate tank near the fuel tank of a diesel vehicle equipped with a selective catalytic reduction system.
diesel fuel: A thicker fraction of crude oil that contains more heat energy and can produce more cylinder pressure and vehicle movement than an equal amount of gasoline.
diesel fuel grades: Standards created to separate diesel fuels into three groups.

Copyright Goodheart-Willcox Co., Inc.

diesel fuel injection: High-pressure, mechanical/hydraulic system that delivers fuel directly into a diesel engine's combustion chambers.
diesel fuel supply system: System that feeds fuel to an injection pump, normally using an engine-driven inline electric pump, which passes the gas to the fuel lines and nozzles.
diesel injection computer: Monitors injector sensor inputs and calculates the outputs for the actuators to more precisely control the mechanical, high-pressure plungers inside a diesel injection pump.
diesel injection sensor: Sensor that monitors and feeds a signal to the computer for engine temperature, speed, and other variables that affect fuel needs.
diesel injection timing: Controlled by ECM gathered sensor information, it refers to diesel fuel being injected into the combustion chambers in relation to the engine's piston position.
diesel injector heat shield: Outside layer surrounding a diesel injector that protects it from engine heat.
diesel injector needle valve: Precisely machined rod with a specially shaped tip that opens and closes the nozzle (fuel opening).
diesel knock: A rumble or a dull clattering sound from very high cylinder gas pressures produced as the detonation of diesel oil expands and pushes the engine pistons down.
diesel mechanical injection (DMI): Fuel injection system that uses a mechanical, high-pressure, multi-plunger/cam lobe fuel pump with electronic controls.
diesel particulates converter: Device that stores and then burns the ash and soot trying to leave a diesel exhaust system.
diesel prechamber: See *precombustion chamber.*
dieseling: Condition in which the engine continues to run after the ignition key is turned off. A knocking or coughing noise is heard as the fuel ignites and the crankshaft spins uncontrollably. It is also referred to as after-running or run-on.
differential: An assembly of gears used to provide power to the drive axles and allow them to rotate at different speeds as necessary.
differential assembly: Gear system that redirects the power flow and allows the drive wheels to revolve at different speeds when necessary.
differential breather tube: Safety tube that inserts into a hole in a rear axle housing to vent pressure or vacuum in or out of the housing as temperature changes occur.
differential carrier: Enclosure used to mount the differential assembly on the rear axle housing.
differential case: A cast aluminum enclosure within the differential carrier that holds the bearings, ring gear, and spider gears that power the drive axles. It is also called a differential housing.
differential clutch piston: A piston used to apply clamping force to the clutch friction discs and steel plates in a clutch pack.
differential friction disc: Discs covered with a synthetic fiber or ceramic coating to increase surface friction between steel clutch discs in a clutch set.
differential gear: See *spider gear.*
differential housing: See *differential case.*
differential ID number: Identification number located on a differential that provides information on the exact type of differential for ordering parts and looking up specifications.
differential lubricant: Oil (often SAE 80W-90 gear oil) dispersed to all parts of a differential by the movement of the ring gear. It is needed to reduce friction between the moving parts in the rear axle assembly.
differential ratio: See *rear axle ratio.*
differential solenoid valve: Valve that operates the hydraulic spool valve to adjust the amount of clamping force applied to each axle clutch set.
differential voltage signal: Voltage signal used with twisted-pair conductors that consists of two complementary digital signals with opposing polarities.
digital-analog meter: Digital multimeter that has both an alphanumeric display and a bar graph to show fluctuating electrical values.
digital audio player: A compact music player that stores large amounts of digital data on an internal memory chip.
digital electronics: A specialized field of electronics that encompasses the ways in which a computer uses logic gates and the binary numbering system to make complex decisions (outputs) based on specific facts (inputs).
digital instrument: Instrumentation that uses various lights and electronic displays to show operating conditions. An electronic control module is needed to act as an interface between the sensor and the digital readout panel.
digital multimeter: Multimeter that uses a vacuum fluorescent or liquid crystal display to give a digital readout, best suited for measuring constant values.
digital pyrometer: An electronic tool used to take very accurate temperature measurements.
digital radio: Radio that uses analog signals that are compressed and digitized (converted to on-off signals) so more programming can be broadcast in a given spectrum. The signal is similar to the signal produced by a digital compact disc.
digital scope pattern: Oscilloscope readout that has very short, repeating changes in voltage (from no voltage to a few volts dc positive).
digital signal: An electronic signal that uses on and off (or high-low) pulses.
digital thermometer: An electronic device for measuring temperature.
digital video disc (DVD) player: Electronic device that has a display screen and the ability to play high-capacity discs containing video.
dimmer switch: Foot- or hand-operated switch that operates the high and low beam headlights.
diode: A semiconductor device that allows current flow in one direction, but resists it in the other.
diode assembly: See *alternator rectifier.*
diode frame: Case into which the rectifier diodes are mounted.
diode trio: Three diodes connected to the rotor field windings through a connection in the voltage regulator. The three diodes supply current to the field windings.
direct current (dc): Electric current that flows steadily in one direction only.
direct electronic fuel injection (DEFI): Fuel injection system that, in addition to an electric fuel pump, uses a mechanical fuel pump and high-pressure injectors to spray fuel straight into an engine's combustion chambers.
direct gasoline injection systems: See *direct electronic fuel injection (DEFI).*
direct ignition coil: Coil that is bolted directly over the top of each engine spark plug. Coils fire only on the power strokes for maximum voltage and combustion efficiency.
direct ignition system: A computer-controlled ignition system that has ignition coils mounted on top of the spark plugs. This type of system has an individual high-voltage, step-up coil for each spark plug, so there is no need for spark plug wires.
direct injection system: Type of fuel injection system that sprays high-pressure fuel straight into an engine's combustion chambers.
directional tire: High-performance tire designed to rotate in a specific direction to minimize hydroplaning.
disc brake assembly: Consists of a caliper, brake pads, a disc, and related hardware (bolts, clips, springs, etc.).
disc brake pad: Steel plate to which linings are riveted or bonded. Each caliper has an inner and outer brake pad that fits inside the hydraulic brake caliper.
disc brake service: Process that includes replacing worn brake pads, rebuilding the caliper assembly, turning (machining) the brake discs, and bleeding the system.
disc lining: See *friction material.*
discharge: Process of drawing electric current from a battery.
discharge service valve: An A/C service valve that is located at the output from the compressor, in the system high side.
discharge side: See *high side.*
discharging: Current and electrons flowing out of the battery cells, or the release of stored energy. This is a conversion of chemical energy into electrical energy by the battery.
display device: Electronic screen that shows output information in a dash instrument cluster(s) of an automobile. It includes vacuum-fluorescent, liquid-crystal, and plasma displays.
display pattern: See *parade pattern.*
distillation: First conversion process in the refining of crude oil. During this process, a fractionating tower breaks crude oil down into different parts, or fractions.

Copyright Goodheart-Willcox Co., Inc.

distilled water: Water that has been boiled and the vapors collected in a clean container to remove contaminants. This type of water should be added to the liquid electrolyte of lead-acid batteries to prevent impurity buildup within the battery.
distortion: Results when speaker output is not a good reproduction of the original input.
diverter valve: Valve that prevents air from entering the exhaust system during deceleration.
division: Arithmetic process used to determine how many times one number is contained in another number.
dog clutch: Type of clutch that uses fitted driving gear teeth that engage or disengage matching recesses in the driven gear. When engaged, it creates a coupling that rotates at the same speed with no slippage.
dog tracking: Term for when the rear tires do not follow the tracks of the front tires.
DOT serial number: Department of Transportation serial number stamped on a tire sidewall to identify the particular tire manufacturer, plant location, construction, and date of manufacture.
double-Cardan joint: See *constant velocity universal joint.*
dowel: A small protrusion on a bearing bore or cap that fits in a hole in a split-type bearing, positioning the bearing correctly in the bore.
downflow radiator: Radiator design with cooling tubes running vertically through the core and tanks on the top and bottom.
dragging brake: A condition where brakes remain partially applied after the brake pedal is released.
dragging clutch: Problem that occurs when a clutch disc stays engaged to the flywheel—as the clutch pedal is depressed—and drags against it. It can be caused by excessive clutch pedal free travel or a damaged/worn clutch disc.
drain line: Tube connected to the drain passage of a turbocharger that returns oil to an oil pan after passing through the turbo bearings.
drain passage: Machined passage in a turbocharger that funnels oil into the drain line after passing through the turbo bearings.
drill: Tool with a cutting tool attachment or drill bit attachment used to create holes in metal and plastic parts. Drills can be handheld or mounted and use a variety of power sources.
drill bit: Tool piece, available in many different styles and sizes, that fastens into a drill chuck to cut holes in metal and plastic parts.
drilled connecting rod: Type of connecting rod with a machined hole throughout its entire length for supplying oil to the piston pin.
drill press: A large, floor- or bench-mounted drill for drilling large holes, deep holes, or a great number of holes in several parts. A handle controls the drill bit pressure applied to a part.
driveability problem: Term for any vehicle problem that affects the performance of the drivetrain.
drive belt inspection: Process of looking for splits, tears, cuts, and wear on a vehicle drive belt.
drive chain: A chain used to transfer power from an engine crankshaft to the transaxle gearbox, or transmission. It is also called a drive link.
drive link: See *drive chain.*
drive shaft: A steel tube that transfers rotating motion from the transmission to the rear axle assembly of a vehicle. It is also called a propeller shaft.
drive shaft assembly: An assembly consisting of a drive shaft, front and rear universal joints, rear yoke, and front slip yoke. It provides a smooth delivery of power to the rear axle assembly, while allowing the rear axle to move up and down to compensate for road conditions.
drive shaft balancing weight: Small metal weight frequently welded to a drive shaft to smooth operation and reduce vibration.
drive shaft noise: Squeaking, whining, or clunking sound emitted from a drive shaft usually caused by dry, worn universal joints, a worn slip joint and support bushing, or a dry, worn center support bearing.
drive shaft runout: Variation from perfect drive shaft rotation. If runout is too large, the drive shaft will vibrate.
drive shaft vibration: Rapid small or large movement along a drive shaft that can be caused by any problem that affects drive shaft balance, runout, and angle.
drive shaft vibration damper: A large, ring-shaped weight mounted on rubber that helps keep the shaft spinning smoothly by absorbing twisting vibration.
drive trace: A graph showing emission levels over the time of the test.
drive trace report: Printout of the five drive traces (HC, CO, NO_X, CO_2, and purge) normally monitored during an emission test. If there is a problem, a technician can analyze this report to find and repair problem(s) causing the increased air pollution.
drive train: All of the collective parts (engine, transmission, drive shaft, differential, drive axles, etc.) that generate power and transmit it to the wheels.
drive-by-wire system: See *throttle-by-wire system.*
driveline: Term for the components and parts that transfer engine power from a vehicle transmission to its drive wheels.
driveline angle: The angle of a drive shaft installed between a transmission and rear axle assembly. If the angle is too sharp, the universal joints can cause speed fluctuations and vibration.
driven disc: Steel disc with tabs along the outer edge to match to the clutch drum. Discs are placed between driving discs in the clutch assembly and press against them to allow power flow through the transmission.
driver information center (DIC): Small, dash-mounted keyboard display inside the passenger compartment. It gives the driver information on vehicle and outside conditions based on data provided from vehicle sensors.
driver's-side air bag: Air bag located inside the steering wheel that protects the driver from head and chest injury during a high-speed frontal collision.
driving disc: Friction material-coated metal disc with a notched inside edge to match splines on a clutch hub. When the clutch is engaged, it presses against the driven discs to spin them and the clutch drum at the same speed.
driving hub: Metal mounting surface for the wheel. It keeps power moving from the stub axle to the wheel.
driving range: Distance a vehicle can be driven without stopping for fuel or, in the case of hybrid/electric vehicles, to be charged.
driving shell: Metal cylinder that surrounds the secondary clutch assembly and forward planetary gearset. Tabs on the shell connect these componets to the front clutch assembly to transfer power. It is also called the clutch shell.
drop-center wheel: Wheel design in which the center section is smaller in diameter (dropped) from the rim. A tire bead can fall into this recess for easier installation and removal of the tire.
droplight: A portable source of light that can be taken to a repair area under a vehicle or anywhere else in a vehicle.
dropped valve guide: A valve guide that has fallen around the head of a valve after breaking free from its press-fitting.
dropping brake pedal: A condition where the brake pedal slowly moves all the way to the floor when steady pressure is applied to it.
dropping resistor signal: Used to provide input signals to the body or instrumentation electronic control module as varying dc voltage and current signals.
drum brake assembly: A brake assembly consisting of a backing plate, a wheel cylinder, brake shoes and linings, retracting springs, hold-down springs, a brake drum, and an automatic adjusting mechanism.
drum brake service: Removing parts from the backing plate, cleaning and inspecting the parts, replacing the brake shoes, replacing or rebuilding the wheel cylinders, turning (resurfacing) the brake drums, lubricating and reassembling the brake parts, and preadjusting, bleeding, and testing the brakes.
drum brake shoe assembly: Metal shoe with an applied heat-resistant friction material that rubs against a revolving brake drum to produce braking action.
dry-charged battery: A battery that is charged, but lacks electrolyte. It is filled with electrolyte when it is placed into service.
dry park test: Simple test to check the operation of steering system components. While on a level surface or lift, one technician slightly turns the steering wheel right and left as a second technician systematically examines and feels the steering parts for looseness and wear.
dry sleeve: A thin cylinder sleeve that is not exposed to engine coolant.
dry stick (wax) lubricant: Vehicle lubricant used on door latches and strikers.

Copyright Goodheart-Willcox Co., Inc.

dry sump: Engine lubrication system that uses two oil pumps and a separate oil reservoir for superior engine oiling.
dual-bed catalytic converter: A catalytic converter that has two separate catalyst units (a reduction and an oxidation converter) enclosed in a single housing.
dual-clutch transmission: Type of transmission that uses an inner and outer input shaft.
dual exhaust system: An exhaust system that uses separate pipes, mufflers, and catalytic converters for each bank of cylinders.
dual-mass harmonic balancer: Harmonic balancer with one weight mounted on the outside and inside of a crankshaft pulley for high engine speed vibration reduction.
dual master cylinder: Type of master cylinder that has two separate hydraulic pistons and two fluid reservoirs. It is also called a tandem master cylinder.
dual overhead cam (DOHC) engine: An engine equipped with two camshafts in the top of each cylinder head. One cam operates the intake valves; the other operates the exhaust valves.
dual spark plug ignition system: Ignition system that uses two spark plugs in each cylinder. One plug is located near the intake valve; the other is near the exhaust valve.
dual voltage system: Type of electrical system that uses both a 12-volt battery and high-voltage battery, each wired separately. The conventional 12-volt system powers most of the electrical/electronic circuits while the HV battery powers the double-ought (00) conductors and the HV motor-generator of modern electric drive trains.
duct: Plastic tube of various shapes that carries air over the evaporator and the heater core, as well as to the vents.
dummy shaft: A temporary shaft, such as a wooden dowel or a metal rod, used with a hammer to drive a shaft from its housing.
dump mode: A mode of ABS operation whereby the ABS releases hydraulic pressure to one or more of the brake wheel cylinders or calipers.
dump valve: See *turbo blow off valve.*
dust cap: Metal cap installed on the end of an axle or spindle to keep dirt out and grease in.
dust shield: Metal shroud or rubber boot that surrounds a shock absorber rod to keep out road dirt and debris.
duty cycle: The percentage of "on" time for a device that is pulsed on and off.
dwell meter: Tool that measures current flow as compared to degrees of engine crankshaft rotation. It is needed for use on vehicles that have a contact-point or early electronic ignition system.
dwell section: The part of an ignition scope pattern illustrating the buildup of the coil magnetic field as current flows through the primary circuit.
dye penetrant: A testing material that can be sprayed or painted onto iron and aluminum parts to locate cracks.
dynamic engine compression test: A test that measures cylinder pressures with a test gauge while an engine is idling. Exhaust system and intake air issues can be found using the test. It is also termed a running engine compression test.
dynamic imbalance: Unbalanced condition in which the centerline of a revolving object is not in the same plane as the object itself.
dynamometer: Test instrument used to measure power output and performance of an engine. It is also known as a dyno.
dyno: See *dynamometer.*

E

eccentric: An egg-shaped lobe that converts the rotary motion of one part of a mechanism to linear motion in another.
ECM-controlled starting circuit: Automatically energizes and de-energizes the 12-volt starting motor as soon as engine sensors detect fuel combustion and the resulting rapid increase in crankshaft rpms (speed sensor signal).
efficiency: The ability to produce high-quality work at a fast pace.
EFI fuel pressure regulator: Regulator that uses engine vacuum, not the ECM, to control lower fuel pressure in multiport fuel injection systems.
EFI injector operating voltage: Usually 12.5–15 volts dc for nondirect or port injection systems.
EFI tester: A tool used to locate trouble codes and electronically perform diagnostic tests on the electronic fuel injection system of a vehicle.
EGR duty cycle: A measurement of control current on and off time sent from the ECM to meter just the right amount of exhaust gases needed to reduce NO_x emissions.
EGR solenoid valve: A valve that uses an electronic solenoid to block or pass airflow to an EGR valve.
electric air injection pump: Low-pressure pump used to force air into an exhaust manifold. It is driven by a small dc motor, instead of being engine/belt driven.
electric brake caliper: Caliper that uses one or more servo motors to force the brake pads into the rotating brake disc to slow and stop the vehicle.
electric circuit: Consists of the basic components (power supply, load, and conductor) needed to utilize electrical energy.
electric cooling fan: Type of cooling fan that uses an electric motor, coolant temperature sensor, and engine ECM to provide airflow and heat transfer out of a radiator.
electric fuel pump: Fuel pump located either inside the fuel tank or in series with a fuel line; can create almost instant pressure and provides a smooth flow of fuel.
electric fuel shutoff: Solenoid that stops fuel injection when the ignition key is turned off.
electric motor: An electric device that uses the principles of magnetism to produce powerful rotating action.
electric oil pump: Electric pump that provides hydraulic pressure for clutch application to lock each drive flange to the ring gear.
electric parking brake: Parking brake system that uses a dash-mounted switch and an electric servo motor to mechanically apply the rear brake.
electric PCV valve: ECM-controlled valve that regulates engine crankcase ventilation.
electric power: The work done by an electric current; measured in watts.
electric shift solenoid: Electronically controlled solenoid in an automatic transmission that operates a spool valve located in the valve body.
electric shock: The result of current passing through the tissue of the human body, which can cause injury or death.
electric tool: A tool powered by electricity.
electric water pump: Large dc motor and impeller that forces coolant through the engine's water jackets or through an HV cooling system. It is used in place of a belt-driven water pump.
electrical device: A component that uses more than one or two volts of electricity to do work. Examples include an electric motor, relay, solenoid, or lightbulb.
electrical diagnosis: Troubleshooting process that uses a logical sequence of steps to find the source of an electrical problem. A systematic approach, beginning with verifying the problem, narrowing down the causes, performing the proper tests, and then making and verifying the repair, works better than a trial-and-error approach.
electrical ground: Shows where circuits connect or fasten to the metal frame or chassis of a vehicle.
electrical solvent: Solvent used to clean oil and grease from components before soldering. It can also be used to remove soldering flux from a component.
electrically erasable programmable read only memory (EEPROM): A type of memory module in which the programming can be changed by scan tools and other electronic equipment that burns-in the new programming.
electricity: The movement of free electrons from one atom to another.
electro-hydraulic differential: Type of electronic-controlled differential that uses electromagnets to operate hydraulic spool valves.
electrolysis: Chemical conversion process that sends an electric current through water to separate hydrogen atoms and oxygen atoms into separate gases.
electrolyte: Mixture of 35% sulfuric acid and 65% distilled water housed in each cell of a lead-acid battery. This solution creates a chemical reaction that releases electrons. It is commonly referred to as battery acid.
electromagnet: A magnet that is produced by placing a coil of wire around a steel or iron bar. When current flows through the wire, the bar becomes magnetized.
electromagnetic clutch: An electronically controlled clutch on a supercharger pulley used to engage and disengage the drive belt.

Copyright Goodheart-Willcox Co., Inc.

electromagnetic interference (EMI): Electronic noise that is created when two or more wires carrying a strong voltage or signal are allowed to cross. It can also be created by radio waves.
electromagnetism: A branch of physical science that deals with the interaction of electricity and magnetism. Electricity can be used to produce magnetism, and magnetic fields can be used to produce electricity.
electromotive force (EMF): See *voltage*.
electron: A negatively charged particle that circles in a specific orbit around the nucleus of an atom.
electron flow theory: Theory that states that electricity flows from negative (–) to positive (+). Electrons leave the negative terminal of the battery, flow through the circuit, and then re-enter the positive terminal.
electronic coil module: A component in a distributorless ignition system that consists of multiple ignition coils and a coil control unit that operates the coils.
electronic component: A modern solid-state component that uses a semiconductor instead of moving parts while operating on one volt or less of electricity. Examples include diodes, transistors, sensors, and automotive computers. It is also called a solid-state component.
electronic control module (ECM): General term used for any computer that controls a vehicle system. The abbreviation ECM is also used for engine control module.
electronic device: See *electronic component*.
electronic EGR system: Emission control system that uses vehicle sensors, the ECM, and a solenoid-operated exhaust gas recirculation valve to reduce NO_x emissions.
electronic EGR valve: Valve that uses one or more electric solenoids to open and close its exhaust passages. It works without engine vacuum.
electronic four-wheel steering system: Type of four-wheel steering system that has an electric-motor-driven power rack that acts upon the rear wheels via its own recirculating-ball drive and mechanical links.
electronic height control system: A system that uses a height sensor and control module to control the operation of a small electric air compressor, which maintains the correct vehicle ride height.
electronic spark advance systems: Systems that use engine sensors and a computer, or ECM, to adjust ignition timing.
electronic speedometer: Speedometer that uses integrated circuit chips in the dash or a circuit in the ECM to react to electrical signals from the vehicle speed sensor.
electronic steering assist: A small electric motor mounted inside a rack housing that acts upon the rack to aid the driver in steering.
electronic suspension system: Suspension system that uses electronic components to control the operation of the shock absorbers or strut cartridges. Systems vary according to the type and number of input sensors they use, whether or not they are equipped with an air compressor, and the number of wheels they control.
electronic transmission control: System of electronic sensors, actuators, and a transmission module that monitor and precisely control the operation of an automatic transmission.
element: Filter material, usually made of paper, that fits inside the metal or plastic housing of an air filter. *Also*, a group of one type of atom. Hydrogen is the simplest element in the universe.
emergency brake: Provides a mechanical means (cable and levers) of applying the rear brakes. It is also called a parking brake.
emission control information sticker: Sticker normally located in an engine compartment that gives important engine data, evaporative emissions information, schematics, and other specifications for complying with EPA regulations.
emission control system: A system that is used to reduce the amount of harmful substances emitted into the atmosphere by an automobile.
emission maintenance reminder: A circuit that automatically turns on a dash light to indicate the need for emission control system service.
emission standard base line: The average allowable emission level for a specific vehicle model year displayed as a straight dashed line across an emission drive trace report. It is also referred to as a cut point.
emissions testing program: A program that uses exhaust gas readings as the engine operates at idle and at a set rpm to determine if exhaust emission levels are within acceptable state standards. It may also involve checking the vehicle for the presence of a catalytic converter and a fuel inlet restrictor. It is often called an inspection and maintenance program.
end cover: A cap that bolts on a gearbox housing to secure the end of the sector gear.
end gas: Unburned portion, after normal combustion, of an air-fuel mixture.
end seal: A seal that has to be worked down into grooves in an oil pan or front cover and block before being placed over a gasket.
energy reserve module: A module that deploys the air bag after a power failure. It must be removed or allowed to discharge for up to 30 minutes after disconnecting the battery.
engine: A device that converts energy into useful mechanical motion.
engine balancing: Machine-aided process that is needed when the weight of the pistons, connecting rods, or crankshaft is altered by installing new parts. The correct balance of weight within an engine has to be kept during reassembly to prevent major mechanical problems. It is also called crankshaft balancing.
engine bedplate: One-piece metal casting for the bottom of an engine block designed to eliminate main bearing caps. An engine block using this construction is split into an upper and lower half at the main bearings or crankshaft centerline.
engine block: The part of the engine containing the crankshaft, pistons, and cylinders. It is made of cast iron or aluminum and is the foundation for the entire engine.
engine blowby: Oil vapors and other emissions that leak past piston rings into the crankcase.
engine bottom end: Term used for the major engine parts below a cylinder head including the cylinder block, crankshaft, connecting rods, rod bearings, main bearings, piston pins, piston rings, and pistons.
engine control module (ECM): Small computerized unit that monitors and regulates the many components, parts, and systems that operate within a vehicle. The abbreviation ECM is also used for electronic control module.
engine coolant temperature sensor: Thermistor sensor that monitors the operating temperature of an engine. The sensor tip is positioned for exposure to engine coolant.
engine cooling system: System that controls the operating temperature of engine cylinder heads and cylinder block.
engine cough: A mild backfire in the engine intake manifold, quieter than an engine knock or backfire.
engine crane: Device used to remove (raise) an engine from or install (lower) an engine into a vehicle. It has a hydraulic hand jack for raising and a pressure release valve for lowering.
engine displacement: The volume of space in which the piston moves in a full stroke (TDC to BDC) multiplied by the number of cylinders in the engine. It is also termed the engine size.
engine dynamometer: A machine that tests vehicle engine power at the crankshaft (brake horsepower).
engine exhaust leak: Exhaust gas escaping out of an engine part or component. Often produces a clicking sound or metallic noise near the engine.
engine firing order: Refers to the sequence in which the spark plugs fire to cause combustion in each cylinder.
engine floating: A constant engine speed above idle.
engine front cover: A thin, stamped steel or cast aluminum cover that encloses the timing chain or gear mechanism. It blocks dirt and debris while preventing oil leakage. It is also called the timing cover.
engine front end: Term that refers to the camshaft drive mechanism, front cover, water pump, and auxiliary shafts that are attached to the front of an engine.
engine hoist: Machine that lifts an engine from a vehicle's engine bay. It can resemble a small crane with a boom and wheels for positioning, or it can be an overhead mounted machine.
engine idle speed: Operating speed (in rpms) of an engine when the vehicle is in *Park* or *Neutral*.
engine knock: Engine vibration noise caused by detonation in the combustion chamber.
engine load: A percentage measurement that represents how hard an engine is working.

Copyright Goodheart-Willcox Co., Inc.

engine oil: Oil that protects an engine from friction and the resulting heat. It is also called motor oil.
engine oil debris: Bits of rubber, plastic, aluminum, titanium, steel, brass, ductile iron, etc., that can collect in a vehicle oil pan and filter.
engine oil leak: Oil leakage as a result of hardened or cracked gaskets, worn seals, loose fasteners, or damaged parts.
engine operating temperature: The temperature of the engine coolant during normal engine operating conditions.
engine overhaul: A process that includes complete disassembly of the engine; cleaning, inspection, and measurement of critical parts; replacement or service of worn or damaged parts; and reassembly of the engine. It is also called engine rebuild.
engine performance problem: Any trouble that lowers engine power, performance, fuel economy, or alters emissions.
engine power balance test: Test that involves disabling a fuel injector or spark plug in a specific engine cylinder while monitoring the corresponding rpm drop to measure cylinder power output. It is also called a cylinder balance test.
engine-powered fan: Fan that is bolted to an engine water pump hub and pulley. This type of fan has generally been replaced by electric fans.
engine rebuild: See *engine overhaul.*
engine sensor: Sensor that monitors variables within an engine and communicates with the ECM to control these factors based on operating conditions.
engine size: See *engine displacement.*
engine sludge: Black, mushy deposits found in the interior of the engine caused by oxidized petroleum products mixed with dirt and other contaminants.
engine sludging: Chocolate pudding-like oil formation resulting from extremely worn oil.
engine smoke: Smoke exiting a tailpipe when engine speed is increased or decreased. Its color can help diagnosis engine problems.
engine speed sensor: A sensor that sends information on engine speed and piston location to the ECM.
engine stand: A metal framework on small casters or wheels that is used to hold an engine for disassembly and reassembly.
engine starting system: System that cranks the engine until fuel combustion forces the pistons down and the engine can operate on its own power. In hybrids and ECM-controlled starting circuits, this system can shut off the engine when it is not needed.
engine temperature gauge: Dash-mounted gauge that indicates engine temperature.
engine throttle actuator: A small, reversible servo motor that is controlled by the ECM and opens and closes the engine throttle valve electronically.
engine throttle valve: Flap-type valve in a throttle body assembly that controls airflow and engine power output.
engine top end: Term for the parts that fasten above the engine's short block. They include the cylinder head assembly, valve train, valve cover, and intake and exhaust manifolds.
engine torque: A rating of the turning force at an engine crankshaft.
engine vacuum leak: Loss of engine vacuum pressure that can be heard as a hissing sound, which is loudest at engine idle speed.
engine vacuum test: Test that measures the strength of the vacuum created by engine cylinders during the intake stroke. It is an easy way to check for a clogged or restricted exhaust system.
engine valve train: The valves and the parts that operate them, including the camshaft, lifters, push rods, rocker arms, valves, and valve spring assemblies.
entrepreneur: Individual who starts and runs his or her own business, assuming all of the responsibilities of business ownership.
equivalent resistance: The total resistance of a series-parallel circuit found by calculating the resistance of each parallel section and then adding the series resistances to these values.
erasable programmable read only memory (EPROM): A type of microprocessor whose programming can be altered only by erasing it with special equipment and reprogramming.
ethanol: See *ethyl alcohol.*
ethical behavior: Actions conforming to accepted standards of fairness and good conduct that are based on an individual's sense of what is right and wrong.
ethyl alcohol: A colorless, toxic, and highly flammable liquid made from farm crops like grain, wheat, sugarcane, or potatoes. It is also called grain alcohol or ethanol.
evacuation routes: Designated paths that are used to show people how to exit a building quickly during a fire, gas leak, or other emergency.
evaporation: A liquid changing into a vapor (gas) state.
evaporative emissions control (EVAP) system: An emissions control system designed to prevent fuel vapor from escaping into the atmosphere.
evaporative emissions system pressure test: Additional IM 240 test that checks an EVAP system for leaks into the atmosphere. Pressure test equipment is connected to the system's vapor vent line. A computer then meters low pressure nitrogen into the system and closes it off while monitoring for a pressure drop.
evaporative emissions system purge test: Additional IM 240 test that measures the flow of fuel vapors into an engine. A flowmeter transducer is installed into the system purge line and a computer connects to the transducer for data analysis.
evaporator: A heat exchanger installed in the air conditioner blower case. Absorbs heat and humidity from the incoming air and transfers it to the circulating refrigerant.
event data recorder: A device that monitors and records vehicle operating conditions and stores them in memory.
excess crankshaft end play: Too much front-to-back movement of a crankshaft usually caused by a worn main thrust bearing.
excessive brake pedal effort: A noticeable increase in the amount of foot pressure needed to apply the brakes.
exhaust back pressure: Pressure created in an exhaust system by the flow of exhaust gases. Back pressure must be as low as possible to improve engine efficiency and prevent engine overheating.
exhaust camshaft phaser: Aids in lower emissions by closing the exhaust valves before all of the end gas has been expelled from the cylinder.
exhaust emission readings section: Part of a vehicle inspection report that gives readings for HC, CO, and NO_x, and OBD results, if applicable, from an emission test. Standard vehicle emission levels are listed along with the test results.
exhaust gas: Harmful chemical or fume produced from the combustion of hydrocarbon-based fuels (or most other fuels) within an engine.
exhaust gas analyzer: Electronic test device used to measure the amount of pollutants in exhaust emissions.
exhaust gas recirculation (EGR) system: System that injects burned exhaust gases into the engine intake manifold to lower the combustion temperature and reduce NO_x pollution.
exhaust gas sensor: See *oxygen sensor.*
exhaust leak: Pressure leak in a vehicle exhaust system that will often show up as gray or white carbon lines coming from the openings.
exhaust manifold: Connecting pipes between the cylinder head exhaust ports and the exhaust pipes.
exhaust manifold doughnut: Gasket or an O-ring that seals the connection between an exhaust manifold outlet and header pipe to prevent leakage.
exhaust manifold warpage: Condition in which the deck on an exhaust manifold is no longer flat.
exhaust note: Sound of engine exhaust gases.
exhaust pipe: Welded, rust-resistant steel tube connecting major parts of a vehicle exhaust system.
exhaust ports: Passages leading from the combustion chambers to the exhaust manifold to carry burned gases out of the cylinders.
exhaust stroke: The portion of the piston's travel that is devoted to expelling the burned fuel charge.
exhaust system: Components that quiet and carry exhaust emissions to the rear of a vehicle. These components include the muffler, exhaust pipes, catalytic converter, and exhaust manifold.
exhaust system back pressure test: Test that measures the amount of resistance to gas flow in a vehicle exhaust system.
exhaust system clamp: U-bolt for connecting parts of an exhaust system together.
exhaust system inspection: Process of checking exhaust pipes and exhaust system components for damaged, rusted, or leaking parts.
exhaust valve: Valve located over the cylinder head exhaust port that controls the flow of burned gases out of the combustion chamber.

Copyright Goodheart-Willcox Co., Inc.

expanded display: Oscilloscope control that allows one cylinder waveform to be displayed above the parade pattern. It is also referred to as cylinder select.
expansion: Rapid enlargement of gases in an engine due to combustion.
expansion freeze plug: Type of freeze plug available for tight quarters. An expansion freeze plug is placed into an engine hole and a screw is tightened on the plug, allowing it to expand and lock in the hole.
expansion tube: In an A/C system, a fixed opening that meters the refrigerant flowing into the evaporator. It is also called an orifice tube.
expansion valve: A temperature-sensitive valve that controls refrigerant flow and the evaporator temperature.
exploration tests: Various tests used by oil companies to determine the probable location of crude oil underground. These tests include seismic studies, surface mapping, and test drilling.
explosion: A violent expansion of gases due to rapid combustion of volatile materials.
extension: Socket wrench lengthening accessory that is placed between a socket and its handle to allow access to difficult-to-reach fasteners.
extension housing: An aluminum or iron housing bolted to the back of a transmission case that supports the end of a transmission output shaft. A gasket fits to the front and a seal to the rear to stop oil leakage. It is also called the tail shaft housing.
extension housing bushing: Solid, plain bushing that fits inside a transmission extension housing to support the slip yoke as it spins in the transmission.
external cylinder power steering system: Power steering system with the power piston assembly as a separate part bolted to the vehicle frame and center link.
external lifter wear: Results in the bottom of a lifter becoming flat or concaved. This is due to friction between the lifter and camshaft lobe.
external oil leakage: Darkened, oil-wet areas on or around an engine.
eyewash station: Station used to wash chemicals from a technician's eyes after an accident by flushing them with water.

F

facing: See *friction material.*
facing spring: Flat, metal spring located behind the friction material on a clutch disc. It compresses inward with the friction material to smooth initial clutch engagement. It is also called a cushioning spring.
fail-safe circuit: Circuit designed into the voltage regulator that disconnects alternator output if voltage levels become too high.
failure record: ECM documentation of the number of times (keystarts or warm-ups) a particular trouble code has occurred.
falling edge: Oscilloscope reading that shows the drop in voltage of a square wave back to zero. It is also called the trailing edge.
fan: A mechanically or electrically operated device designed to create a moving stream of air, generally for cooling purposes.
fan motor: A small direct current motor with brushes that mounts on a bracket secured to the radiator and drives the electric cooling fan.
fan spacer: Part that fits between an engine-powered fan and pulley to move the fan closer to the radiator.
fan switch: A temperature-sensitive switch that controls fan motor operation. It is also called a thermo switch.
farad (F): The size, or electrical storage ability, of a capacitor. A one-farad capacitor connected to a one-volt source stores 6.28 × 1018 electrons.
fast charger: Machine that forces a high current flow into a battery for rapid recharging. The charge rate should not exceed 35 amps and battery temperature cannot exceed 125°F (52°C) or battery damage can result. It is also called a boost charger or quick charger.
fast control area network (F-CAN): A computer communications system that operates at 500 kbps (kilobits per second). It is used to control the engine, transmission, air bags, and other more critical systems.
fastener: Device used to hold, or fasten, parts together. Metal and plastic ones are found on vehicles.
fault designation: Last two digits of an alphanumeric trouble code that pinpoint exactly which component or circuit of a vehicle system might be at fault, as well as the type of problem.
faulty oil pressure switch: Malfunctioning switch that can make the indicator light glow or the gauge read low when oil pressure is normal.
feathered edge: A tire wear pattern in which one side of each tread rib is sharp and raised and the other side of each rib is rounded or recessed.
feeler gauge: A flat, thin strip of metal or small caliber wire, machined to a specific thickness, which is used to measure clearances or gaps.
fender cover: Cover placed over fenders, upper grilles, or other body sections to prevent panel or paint damage during a repair.
fiber optics: A field of electronics in which light is used to carry data through small strands of plastic or glass fiber. Also, refers to cable that has light-carrying strands of plastic or glass.
field winding: Insulated wire looped around iron pole shoes that are attached to the inside of the starter motor housing.
filament: Resistance wire inside a lightbulb that produces heat and the emission of light energy when electrical current is passed through it.
file: An abrasive tool rubbed across surfaces to smooth them. Files are classified by length, shape, and cutting surface.
filler cap: Cap that screws onto the end of a filler neck in a vehicle fuel tank assembly. It is more commonly known as a gas cap.
filler neck: Extension tube that leads from a vehicle fuel tank through the body, allowing a gas pump nozzle to be used to fill the tank with fuel.
filter bypass valve: Valve that opens to protect an engine from oil starvation if the oil filter element becomes clogged.
filter element: A paper or cotton filtering substance mounted inside a filter body that allows liquid or air to flow but traps small debris.
fire: The result of heat, fuel, and oxygen in the correct proportions to start combustion. Many automotive shop supplies and repair procedures can cause fires if not properly handled.
fire extinguisher: Container filled with chemicals that will quench a fire when sprayed on the flames.
firing line: The tall spike shown on an oscilloscope, representing the voltage needed to make the spark jump the plug gap.
firing section: Section of an oscilloscope pattern that shows voltage fluctuations as a spark plug fires.
five-gas exhaust analyzer: Exhaust gas analyzer that measures the amount of hydrocarbons (HC), carbon monoxide (CO), oxides of nitrogen (NO_x), carbon dioxide (CO_2), and oxygen (O_2) in a vehicle's exhaust gases.
fixed caliper: Brake caliper that is rigidly mounted to the spindle and does not move during braking.
fixed dwell: Dwell timing that should remain the same at all engine speeds.
fixed transmission solenoid: Solenoid that uses only fully "on" or "off" signals when directing a spool valve to open or close a fluid pressure passage.
flame arrester: A metal mesh sometimes located before an engine intake manifold. It prevents the flame of an engine backfire from entering the air filter.
flash erasable programmable read only memory (FEPROM): A type of ECM memory that contains vehicle operation data. It is normally reprogrammed rather than replaced.
flash-to-pass feature: Turn signal lever position that allows the driver to flash the high beam lights, indicating to other drivers ahead of the desire to pass.
flasher: Component that makes and breaks the circuit to make the vehicle lightbulbs flash on and off. Usually, one flasher is used for the turn signals and another for the emergency flasher lights.
flat: Term for a tire that has lost all or most of its air pressure due to a leak or other damage.
flat head engine: Engine in which both the intake and exhaust valves are located in the engine block. It is also called an L-head engine. This construction is no longer used in automobile engines but functions in small gas engines.
flat-rate manual: A publication that lists the flat-rate times for a variety of repairs.
flat-rate time: The average amount of time it will take a technician to do a specific repair.

Copyright Goodheart-Willcox Co., Inc.

flex fan: A fan with blades that alter airflow with engine speed.
flex fuel vehicle: See *flexible-fuel vehicle (FFV).*
flexible coupling: Coupling that connects a steering shaft and steering gear input shaft to help keep road shock from being transmitted to the steering wheel.
flexible hose: Hose with an accordion shape and pleated construction that allows it to bend at different angles without collapsing and blocking flow.
flexible-fuel vehicle (FFV): Vehicle designed to operate on different types of fuel, such as E-85. Sensors monitor the contents of the fuel through measurement of combustion efficiency, and engine functions are adjusted for maximum efficiency for the type of fuel being consumed.
flight record test: Test that uses a scope connected to the vehicle during a test-drive to store a problematic sensor or actuator waveform in the scope's memory the moment it occurs.
floating caliper: A caliper that can move or "float" back and forth in relation to the rotor.
floor jack: Movable jack used to raise and lower either the front, sides, or rear of a vehicle.
fluid coupling fan clutch: Type of fan clutch operating in silicone-based oil designed to slip at higher engine speeds to save energy.
fluid leak: Vehicle fluids escaping from bad gaskets, seals, or hoses; cracks in parts; and similar problems.
fluid temperature sensor: Sensor that monitors and reacts to maintain normal vehicle shifting when temperature variations change transmission fluid viscosity.
fluorescent penetrant: Testing material that can be sprayed or painted onto iron and aluminum parts to locate cracks, but requires an ultraviolet (black) light to illuminate.
flushing: Process that drains old fluid from a vehicle system. A cleaning chemical is then sometimes run through the system before new fluid is added.
flux: Lines of magnetic force moving through a magnetic field. *Also,* material used to prevent oxidation of metal being soldered or brazed.
flux brush: Brush that is used to apply a paste-type flux to a joint.
flywheel: A large heavy wheel that forms the base for the starter ring gear, connects the crankshaft to the transmission or transaxle, and provides a mounting surface for the torque converter or clutch assembly.
flywheel battery: See *flywheel generator.*
flywheel generator: A generator that uses the kinetic energy of a high-speed ac armature (flywheel) to store huge amounts of electrical energy. It is also called a flywheel battery.
FM radio: Radio designed to receive a radio signal that varies in frequency (fluctuating speed). The FM band is from 88-108 megahertz (MHz).
footprint: Term for the shape and amount of tire tread touching a road surface.
force: A pushing or pulling action on another object measured in pounds or Newtons.
fork tool: Two-pronged tool shaped like a fork and used to force a ball joint from a steering knuckle with the help of a hammer.
forward bias: Arrangement in which a diode acts as a conductor.
forward-biased diode: Diode that acts as a conductor, allowing current to pass through the diode when voltage is connected in a certain way.
four-bolt main block: Design with four cap screws holding each main bearing cap to a cylinder block. This reduces the amount of crankshaft flex as compared to using just two bolts.
four-channel ABS: Has a separate hydraulic control circuit for each wheel that keeps any one of the four tires from skidding.
four-gas exhaust analyzer: Exhaust gas analyzer that measures the quantity of hydrocarbons (HC), carbon monoxide (CO), carbon dioxide (CO_2), and oxygen (O_2) in a vehicle's exhaust gases.
four-stroke cycle: Every two up and two down strokes of the piston results in one power-producing cycle. Two complete revolutions of the crankshaft are needed to complete one four-stroke cycle.
four-valve combustion chamber: Combustion chamber with two intake valves and two exhaust valves for each engine cylinder to increase flow in and out.
fractionating tower: Tower used in the distillation process that separates parts of crude oil as the oil vaporizes up through the tower.
frame: The steel structure that supports or is part of the vehicle's body.
frame-ground circuit: A circuit that uses the metal frame structure of the vehicle to return electricity to the power source. It is also called a one-wire circuit.
free electron: Electron that moves from atom to atom.
free-floating piston pin: Piston pin that will turn in both the rod and piston.
free travel: Distance a clutch pedal or clutch fork travels before engaging the throwout bearing to push against the pressure plate. It is necessary for proper clutch engagement.
freeze frame: Scan tool snapshot of all vehicle monitored components when a trouble code occurs or when triggered during a drive.
freeze plug: A stamped metal disc pressed or screwed in the holes where the engine core was removed from the casting. The plug allows for expansion if coolant should freeze, preventing a cracked casting. It is also called a core plug.
freeze spray: Solution used to find intermittent electrical problems by lowering the temperature of a component instantly.
Freon: See *refrigerant-12.*
frequency: The number of times that an activity, such as a vibration or the cycling of ac voltage, occurs over a set time period. Measured in Hertz, in which the time period is one second.
friction bearing: A plain bearing that has a smooth surface of soft metal, such as copper or babbitt, on which a part slides or rotates.
friction disc: See *clutch disc.*
friction material: Heat-resistant linings and surfaces applied to different part surfaces to create a strong bonding face. It is also known as disc lining or facing.
frictional horsepower (fhp): The power needed to overcome engine friction and a measure of the resistance to movement between engine parts.
front bearing cap: See *front bearing hub.*
front bearing hub: Metal sleeve that bolts to the front of a transmission case to support the input shaft and clutch release bearing. It is also known as a front bearing cap.
front cover: Cover bolted over the crankshaft snout that holds an oil seal to seal the front of the crankshaft.
front drive axle: Shaft that transfers power from the front differential or transaxle to the vehicle's front wheels. The front drive axles are straight steel shafts when used with a solid differential assembly. When used with an independently sprung differential, the axles are equipped with cross-and-roller U-joints or CV joints for flexibility.
front O_2 sensor: See *primary oxygen sensor.*
front oil seal: A seal press-fitted into the engine front cover that prevents oil leakage between a crankshaft and engine front cover.
front transmission bearing: Bearing positioned in the front of a transmission that supports and controls input shaft movement.
front universal joint: Flexible joint that fastens the slip yoke to a drive shaft.
front-wheel-drive vehicle: Configuration with the drive wheels located in the front of a vehicle, with the engine and transaxle placed directly above. All of this weight in the front of a vehicle provides superior traction.
frozen valve: See *stuck valve.*
fuel: Any substance (liquid, gas, or solid) that can easily be burned to produce heat.
fuel cell: Device filled with electrolyte and made of a plastic, gas-permeable membrane sandwiched between a positive and negative electrode plate that combines hydrogen and oxygen to produce electrical energy. It is electrolysis in reverse.
fuel delivery system: Subsystem of an electronic vehicle fuel injection system that feeds clean, liquid gas from the storage tank to the engine.
fuel efficiency: EPA numerical test rating for the distance a vehicle can travel on one gallon of fuel.
fuel filter: Screening that removes contaminants such as water, rust, and other debris in fuel and prevents them from entering the fuel system.
fuel heater: Electric heating element in a fuel line, positioned ahead of the injection pump, that warms diesel fuel to prevent it from gelling. This system accessory is needed in very cold climates.

Copyright Goodheart-Willcox Co., Inc.

fuel hose: Synthetic rubber hose that carries fuel from the tank to the vehicle engine.
fuel injection system: System that sprays fuel directly into or just ahead of engine cylinders.
fuel injector: Valve controlled by electronic solenoid or spring pressure.
fuel injector boot: Soft rubber grommet or O-ring that fits between a fuel injector and its opening in an engine to prevent engine vacuum leakage.
fuel injector cleaning tool: Tool that uses shop air pressure to force a cleaning solution through fuel injectors to remove deposits.
fuel injector impedance test: Test that measures the internal resistance of injector coil windings while carrying a full amp load to determine how quickly the injector will open.
fuel injector pulsed flow test: Test that fires an injector several times with a normal pulse width to check pintle response.
fuel injector scope test: Test that measures the maximum and minimum injector voltages and time of injection in milliseconds to see if an injector is working properly.
fuel line: Double-wall steel tubing that carries fuel from the tank to the vehicle engine.
fuel line freeze: A problem (usually with diesel fuel) that results when moisture in the fuel turns to ice within the fuel line or engine.
fuel log: See *fuel rail.*
fuel metering system: Subsystem of a vehicle fuel system that gauges the correct amount of fuel to inject into the engine cylinders, depending on engine speed, temperature, load, throttle position, and other factors.
fuel pressure regulator: System that controls the amount of fuel pressure in a vehicle fuel rail.
fuel pressure relief valve: Threaded service valve in low-pressure electronic fuel injection systems that is used for manually "bleeding" any remaining gasoline pressure in the fuel rail and injectors.
fuel pressure sensor: Sensor, mounted on a fuel rail, that sends an electronic signal, proportional to the pressure inside the rail, to the ECM to control fuel pump speed and/or fuel injector pulse width.
fuel pump: Pump that draws fuel out of the fuel tank and forces it to the engine under pressure.
fuel pump capacity: Measurement of the amount of fuel the pump can deliver in a specific amount of time. It is also termed fuel pump volume.
fuel pump charging stroke: Stroke of a mechanical fuel pump during which the eccentric lobe pushes on the pump rod and plunger, compressing the pump spring and pushing the plunger into the pumping chamber, pressurizing the chamber.
fuel pump pressure stroke: Stroke of a mechanical fuel pump during which the eccentric lobe rotates away from the fuel pump, releasing the pump spring so it can pull the plunger and rod in the other direction. This snaps the outlet valve closed and pushes the inlet valve open so the pumping chamber can be refilled with fuel from the tank.
fuel pump testing: Testing that procedurally varies by vehicle but involves measuring fuel pump pressure and volume.
fuel pump volume: See *fuel pump capacity.*
fuel rail: A larger-diameter fuel line that feeds fuel to the inlet openings of the fuel injectors. Its larger size compared to the standard fuel line prevents any injector from starving for fuel under high-demand conditions. It is also called a fuel log.
fuel return system: System featuring a fuel return line that carries excess fuel back to the tank. This keeps engine heat from overheating gasoline by constantly circulating unused fuel back to the fuel tank.
fuel strainer: A semi-porous metal bag that attaches on the inlet of an in-tank fuel pump to keep debris from entering the system.
fuel supply system: Subsystem of a vehicle fuel system that draws fuel from the fuel tank and forces it into the fuel metering device (usually gasoline injectors). It consists of a fuel tank, lines, pumps, and filters.
fuel system: Vehicle system and set of components to store fuel and deliver a combustible air-fuel mixture to the engine cylinders as needed.
fuel system monitoring: A check of whether a stoichiometric, or theoretically perfect, fuel mixture is being fed to an engine.
fuel system service fitting: Part often provided on low-pressure electric fuel injection systems for releasing and measuring fuel pressure.
fuel tank: Safe storage unit for gasoline, diesel fuel, gasohol, alcohol, LPG, or other combustible material used to power a vehicle.
fuel tank baffle: Metal plate located inside a fuel tank that restricts fuel movement while the vehicle operates.
fuel tank capacity: Volume of fuel (in gallons or liters) a fuel tank can hold. Average automobile fuel tank capacity is 12–25 gallons (45–95 liters).
fuel tank pressure sensor: Sensor installed in vehicles equipped with OBD II systems to monitor the buildup of fuel tank pressure.
fuel tank strap: Thick steel band that bolts around a fuel tank to secure it to a vehicle.
fuel temperature sensor: Sensor monitoring the temperature of fuel in a vehicle fuel rail. Fuel temperature has a slight effect on a fuel density.
fuel trim malfunction trouble code: Diagnostic code set if an ECM is having difficulty maintaining engine air-fuel ratio.
fuel vapor: Various chemicals that enter the air as fuel evaporates.
full-electric vehicle: Vehicle that uses only an electric propulsion system to move. An internal combustion engine, or other source to recharge the HV battery when driving, is absent from the vehicle.
full-floating piston pin: A piston pin that is free to rotate. It is secured in place with snap rings.
full hybrid: Gas-electric hybrid vehicle that initially uses a motor-generator for acceleration and propulsion. Once the HV battery is discharged, the internal combustion engine is used to both propel the vehicle and recharge the HV battery.
full power charge mode: One of three modes for a direct electronic fuel injection system that produces a homogeneous, rich mixture (more fuel) that generates the most combustion pressure and power of the three.
full-size spare: Type of vehicle spare tire that is the same size and type as the tires currently mounted on a vehicle.
full-time hub: Type of locking hub in a four-wheel-drive vehicle that is always locked to drive the front wheels.
full-wave rectification: The process of converting alternating current to direct current, allowing both halves of each AC wave through. Both halves flow in the same direction.
fully counterweighted crankshaft: Crankshaft with weights formed opposite every rod journal. Vibration during operation is less than with a partially counterweighted crankshaft.
fully synchronized transmission: Type of manual transmission that uses a synchronizer with all forward output gears. This setup allows a driver to downshift into any lower gear (excluding reverse) while the vehicle is still in motion.
fuse: Device that interrupts current if a circuit is overloaded or a short occurs.
fuse link: A special calibrated wire installed in a circuit that will allow an overload condition for short periods. A constant overload will melt the wire and break the circuit.

G

gas cartridge: Hybrid air bag device that contains inert argon gas pressurized to 3000 psi (20,700 kPa) used to inflate air bags.
gas-charged shock absorber: Type of shock absorber that uses a low-pressure gas to help keep the oil around the shock piston from foaming.
gasket: A soft, flexible material placed between two parts to prevent leaks.
gasohol: Fuel mixture of gasoline and alcohol. Usually, gasohol uses a mix of 2–20% grain alcohol and the rest 87 octane gasoline.
gasoline: Refined, abundant, and highly flammable product of crude oil that is the most common type of automotive fuel. Additives are added to gasoline to improve its operating characteristics.
gasoline engine boost pressure: Averages a turbocharger inlet pressure of around 10–15 psi (0.7–1.0 Bar) in passenger vehicles.
gasoline engine compression reading: Should be around 125–175 psi (860 kPa to 1200 kPa) in each cylinder. Readings must be within about 10–15% of each other.
gasoline injection system: System that uses pressure from an electric or mechanical fuel pump to spray fuel into an engine's intake manifold (multiport or manifold injection) or its combustion chambers (direct injection).
gassing: Formation of acid fumes during the chemical reaction inside the battery. This involves the conversion of water in the electrolyte into hydrogen and oxygen.

Copyright Goodheart-Willcox Co., Inc.

gate: Indented metal part mounted on a shift rail. It aids in locking a shift fork into the correct synchronizer during gear shifts. *Also*, an electronic circuit that produces a specific output for a given input.
gauge tester: Variable resistor test tool used to check gauge and sending unit operation.
gear: An object, either disk- or cone-shaped, into which a series of teeth are cut on its rim.
gear backlash: Term for the measured clearance between meshing gear teeth that allows for lubrication and expansion during operation. In general, the greater the amount, the more play there will be between two meshing gears.
gear-driven oil pump: Type of pump that uses the engine timing gears for power.
gear housing: Metal housing that holds the pinion gear and the rack in a rack-and-pinion steering system.
gear oil: Heavy oil that provides lubrication for the gears and bearings in rear axle assemblies and in manual transmissions and transaxles.
gear oil pump: A type of pump that uses meshing gears to provide pressure and fluid movement.
gear preload: A small amount of pressure applied to differential bearings to remove play and excess clearance with gears.
gear ratio: The relationship between the number of turns made by a driving gear to complete one full turn of the driven gear. If the driving gear makes four revolutions in order to turn the driven gear once, the gear ratio would be four to one (4:1). It can also be determined by dividing the number of teeth on the driven gear by the number of teeth on the drive gear.
gear reduction: A setup in which a small gear is used to drive a larger gear to produce an increase in torque. The speed at the output shaft will be less than the speed of the input.
gear shift lever: Hand-operated lever used in a manual transmission to select the proper gear after depressing the clutch pedal.
gearbox: A transmission (usually worm and ring gear) in a power window motor that changes the rotating motion of the motor armature into a partial rotation of a larger gear.
gearbox housing: A metal case that bolts to a vehicle frame or reinforced area of a unibody to provide an enclosure for the components of worm-type steering gearbox.
gearbox ratio: A comparison between steering wheel rotation and sector shaft rotation. Steering gearbox ratios range from 15:1 to 24:1. It is also termed steering ratio or steering gear reduction.
gel battery: Type of lead-acid battery that contains the electrolyte in a paste-like consistency instead of a liquid. This allows the battery to still function without any electrolyte leakage if the battery case breaks.
general circuit failure: Specific type of computer system failure caused by a component that has no output or has an output that is out of specifications.
global navigation satellite system (GNSS): See *global positioning system (GPS).*
global positioning system (GPS): Uses a series of Earth-orbiting satellites to communicate through a vehicle's antenna the location and time information anywhere near Earth's surface. It is also known as a global navigation satellite system (GNSS).
glow plug: A heating element used to help diesel engines start when cold.
glow plug analyzer: Test equipment used to test diesel glow plugs and the operating condition of a diesel engine. It measures the internal resistance or current to each glow plug and glow plug temperature to detect a dead cylinder.
glow plug control circuit: Circuit that monitors engine temperature and automatically disconnects glow plugs after a few seconds of operation.
glow plug resistance-balance test: Test that monitors the temperature and internal resistance of a glow plug within a cylinder as combustion occurs. A cylinder firing correctly will raise these two elements of its glow plug.
grabbing brake: Brakes that apply too quickly, even with light brake pedal application.
grabbing clutch: Problem that occurs when a clutch disc engages with a jerk or shudder no matter how slowly and carefully pressure is applied to and released from the clutch pedal. It is also referred to as a chattering clutch.
grain alcohol: See *ethyl alcohol.*
graphite: A soft form of the element carbon that adds flexibility, corrosion resistance, and helps retard scoring caused by grit when used as a lock lubricant.
grease gun: Battery- or air-powered tool used for dispensing lubricant into different vehicle components. Its design allows for quick and precise application, especially in difficult-to-reach areas.
grease job: Process of lubricating high-friction areas on the suspension, steering, and drive train systems.
grease seal: Seal that holds lubrication in the axle and the knuckle or bearing support.
grid repair agent: A substance that conducts electricity and is used to repair a broken heating grid within glass.
gross horsepower (ghp): The brake horsepower of an engine with optimum fuel and ignition settings and without allowing for power absorbed by the engine-driven accessories.
ground: The terminal of the battery connected to the vehicle's frame.
ground-circuit resistance test: Test performed by placing the voltmeter across the negative battery terminal and alternator housing.
ground prong: The round, third prong on an electrical plug. If a short develops in the electrical equipment, current passes through this connection to ground because of its low resistance.
grounded circuit: Type of short circuit in which current flows directly into a ground that was not part of the original circuit.
grounded side electrode: Part of a spark plug that causes the electricity to jump the gap and return to the battery through frame ground.

H

hacksaw: A type of saw used to cut metal objects. Blades of various lengths can be mounted in the saw's adjustable frame.
half-wave rectification: The process of converting alternating current to direct current, allowing only half of each AC wave through. In this configuration, a single diode is used in series with an AC source.
halogen lightbulb: A bulb that uses tungsten and halogen gas to produce light. It is brighter than an incandescent bulb.
hanger: Fastening device for securing an exhaust system to the underside of a vehicle.
hard failure: An always present computer system failure that sets a diagnostic code as soon as the ignition key is turned to run.
hard ring coating: Coating of a piston ring made from chrome or moly. It is used to increase ring life and reduce friction only in new or freshly machined cylinders.
hard starting: Excessive cranking time is needed to start an engine.
hard steering: Term for a steering problem that requires a driver to use excessive force and effort to turn the steering wheel/vehicle. It can be a common problem with power steering systems.
harmonic balancer: A round metal or rubber device mounted to a crankshaft to minimize torsional vibration. It is also known as a vibration damper.
harmonic vibration: A high frequency vibration caused by the crankshaft.
harness connector: Multi-terminal connector that joins several wires and consists of a two-part plastic housing that snaps together to prevent the terminals from working free.
harness routing diagram: A diagram that shows how major wiring is arranged and where it is located in the vehicle.
harsh shift: Term for a gear shift in an automatic transmission that happens too quickly, causing the vehicle to jerk.
head gasket: Gasket that creates a seal between engine block and cylinder head surfaces to prevent oil, coolant, and combustion chamber pressure leakage.
head pressure testing machine: Machine that seals all oil and coolant passages before pressurizing an engine head and submerging the head in a water tank to check for leaks.
header: Term for a high-flow, high-performance exhaust manifold sometimes made of stainless steel or lightweight steel tubing.
header pipe: Steel tubing that carries exhaust gases from the exhaust manifold to the catalytic converter.
headlamp system: System consisting of the battery, headlamp wiring, fuse panel, light switch, dimmer switch, headlamps (headlights), taillights, marker lights, and instrument lights.

Copyright Goodheart-Willcox Co., Inc.

headlight aimer: Devices for pointing the car's headlamps in a specified position.
heads-up display (HUD): Display that reflects semi-transparent information onto the windshield or a plastic dash panel so the driver does not have to take his or her eye off the road. It complements the conventional displays in the instrument cluster.
heat checked: Brake discs that have small, hardened, and cracked areas caused by overheating.
heat shield: Sheet of metal or fiberglass used to shelter heat sensitive components, such as wiring, from excessive engine and exhaust heat.
heat shrink tubing: Hollow plastic tubing that shrinks when heat is applied.
heat sink: Metal mount for removing excess heat from power transistors of electronic components. *Also*, a spring-loaded, clamp-on device that is sometimes used to help prevent overheating of electronic components while soldering.
heat-cleaning oven: Machine that circulates superheated air over engine parts to remove organic materials such as oil, grease, paint, varnish, and plastic without the use of chemicals. It is also referred to as a burn-off oven.
heated oxygen sensor (HO_2S): Oxygen sensor that contains a small heater element.
heated seat: Seat that uses a heating element (or multiple heating elements), switch, relay, and related wiring to warm the seat cushions in cold weather.
heated windshield system: Windshield that has a special conductive film sandwiched inside its glass. When high voltage (typically 70 to 90 volts) is passed through this clear conductive film, the glass heats up and melts ice or snow.
heater core: A small, radiator-like unit in the blower case in which coolant circulates. It provides a large surface area for heat dissipation into the passenger compartment.
heater hose: Small-diameter hose that carries engine coolant to the heater core.
heater monitor: Checks the action of the heating element in an oxygen sensor by rapidly turning the heating element on and off while checking its response.
heating system: Uses heat from the engine cooling system to supply warm air into the passenger compartment.
height sensor: Sensor that converts the relative position of a vehicle's body and axle into an electrical signal. Some vary their electrical resistance as the distance changes; others use magnets to vary the magnetic field of the current passing through the sensor as the distance changes.
helical gear: A gear that has teeth cut at an angle, called a helix angle, to its centerline.
hemispherical combustion chamber: A dome-shaped combustion chamber with valves tilted on each side of the chamber and a spark plug located near the center. It provides increased engine aspiration while suffering less heat loss than other designs. The design is commonly nicknamed a hemi.
hertz (Hz): Unit of measure for the frequency of ac current.
hesitation: Condition in which an engine does not accelerate normally when the gas pedal is pressed, or stalls before developing power.
high back pressure: High resistance condition in a vehicle exhaust system that reduces engine power and performance.
high-efficiency air filter: A passenger compartment filter that cleans the air by trapping pollen and other particles in the air.
high fluid level: Overfill of fluid in a transmission that can cause churning and foaming within the system. This may lead to engagement and shifting problems.
high impedance fuel injector: Fuel injector that should have an internal resistance of between 10 and 12 ohms.
high-input failure: Specific type of computer system failure that results when the signal reaching the ECM has more voltage, more current, or a higher frequency than normal.
high-intensity discharge bulb (HID): Lightbulb that uses a high-voltage electric arc between electrodes to excite xenon vapor in the bulb, producing an extremely bright light.
high oil consumption: Lubrication problem caused by external or internal oil leakage, requiring oil to be added to an engine frequently.
high oil pressure: Condition when oil faces too much resistance as it tries to lubricate. It causes the oil gauge to read higher than normal and can cause the oil filter to rupture.
high pressure cutout switch: A/C system control that prevents compressor damage from abnormal operating conditions by opening the compressor coil circuit when discharge pressure is too high.
high-pressure spare: Type of compact spare tire filled to a higher-than-normal air pressure—usually around 60 psi.
high-pressure washer: Engine-powered water pump assembly using a hose and spray nozzle to shoot an adjustable stream of water at various velocities. It is used to remove dirt, oil, and hardened substances from parts.
high side: Part of an A/C system that consists of the parts between the output of the compressor and the flow-control restriction. It is also known as the discharge side.
high-time: See *on-time*.
high-voltage buffer zone: Perimeter of about 3 feet completely surrounding a hybrid electric vehicle, created before servicing the vehicle to prevent electrocution. There should be no other potential conductors of electricity in this area.
high-voltage disconnect: Device on hybrid electric vehicles located near the battery pack, commonly a switch, handle, or connection, that allows the HV battery to be physically disconnected from all vehicle circuits.
hold-down spring: Holds the brake shoes against the backing plate when the brakes are in the released position.
holding device: Device that holds an item or piece in place. It is meant to free a technician's hands to use other tools.
holding fixture: An apparatus used to securely hold heavy or clumsy parts, such as cylinder heads, transmissions, or transaxles during repairs. It is also referred to as a stand.
hole gauge: Gauge for measuring very small diameter holes in parts where an internal micrometer cannot be used.
horn system: Vehicle system that uses a switch mounted on the steering wheel and a relay to send current to the horn. The horn uses a coil-operated diaphragm to produce sound waves and an audible sound.
hose clamp: Tightening device used to secure hoses tightly to their metal fittings.
hose inspection: Process of checking for deterioration, splitting, cracking, or other signs of impending failure in a system's hoses.
hose spring: Spring frequently installed inside the lower radiator hose to prevent the hose from collapsing.
hot spark plug: A spark plug that has a long insulator tip and tends to burn off deposits for a self-cleaning action.
hot spot: Area in an engine suffering from an abnormal buildup of combustion heat.
hot tank: Tank that uses heat and very powerful cleaning agents to clean engine parts. It is used to aggressively remove mineral deposits, hard carbon deposits, oil, grease, and paint.
hot wire: Wire that carries current to the load. It is the part of the circuit between the positive terminal of the battery and the load.
hot wire short to ground: A short that produces low circuit resistance and extremely high current, usually blowing the fuse or circuit breaker.
Hotchkiss driveline: Type of driveline that uses an exposed drive shaft with two universal joints to operate a rear axle assembly. Springs are used on the "live" rear axle to limit movement and twist.
hourly rate: A pay system in which a stated amount of pay is given for each hour worked.
hub: Mounting plate for the wheels on the end of an axle, spindle, or bearing.
hub and wheel bearing assembly: Parts and components that attach a hub and wheel bearings to a vehicle axle. The hub provides a mounting place for a wheel, and along with the wheel bearings, provides a means to transfer axle rotation to the wheels.
hub locknut: Locknut fastener that screws on the end of an axle shaft to secure the hub and other parts of assembly. It is also termed an axle locknut.
hunting gearset: Term for a gearset that does not mesh the same ring and pinion gear teeth during each revolution of the ring gear.
HV: Abbreviation for high-voltage.
HV battery: High-voltage nickel metal hydride or lithium-ion battery capable of 100–300 volts of electricity. They are used alongside a conventional 12-volt lead-acid battery in many hybrid vehicles. They are also called a battery stack or battery bank.

Copyright Goodheart-Willcox Co., Inc.

HV battery amp-hour rating: Rating that compares the electrical power available for one hour of continuous discharge. This is the equivalent of the cold cranking rating.

HV battery cables: Two orange conductor cables that connect direct current to the HV power control module.

HV battery continuous power rating: Measurement of the amount of voltage and current that can be safely generated before the battery is fully discharged.

HV battery control module: Computer that monitors HV battery pack temperatures, input and output levels, recharge and discharge voltages, and battery state-of-charge.

HV battery cooling system: System that uses circulated air or liquid to carry heat away from battery packs and out of the battery housing when under high amperage draw.

HV battery cover: Enclosure that holds high-voltage battery modules to protect against damage.

HV battery ECM: Electronic control module that interprets signals from HV battery temperature and voltage sensors to avoid battery overheating.

HV battery fan: Fan energized by a hybrid vehicle ECM to force fresh air through an air-to-liquid heat exchanger and over the battery pack outer surfaces for cooling.

HV battery frame: Metal holder that secures the battery packs together and attaches them to the vehicle frame.

HV battery nominal operating voltage: The maximum dc voltage available from the HV battery.

HV battery pack: Set of low-voltage battery cells wired in a series to produce a high-wattage means of storing chemical/electrical energy. Each battery pack has six or more battery cells enclosed in a housing.

HV battery peak power rating: Measurement of the amount of current that can be fed to the HV motor for a short period of time. This can determine the vehicle's acceleration speed with full-electric propulsion.

HV battery radiator: Small air-to-liquid heat exchanger mounted in the battery housing. Intake air is routed through the cool fins of an intercooler or heat exchanger before it circulates over battery packs.

HV battery state-of-charge (SOC): Voltage condition of an HV battery usually shown on a hybrid dash display. The value should be at least 80% of maximum voltage rating after a full recharge. When it drops below 20–30%, the motor-generator recharges the battery.

HV battery temperature sensor: Sensor that monitors the temperature of an HV battery to prevent battery thermal and overheating damage.

HV capacitor bank: Electrical energy storage device that does not require an electrolyte, but consists of at least two electrical conductors separated by an insulator. HV capacitor banks are light, wear-proof, and can accept or output short bursts of high-power electrical energy.

HV ECM cooling system: System that forces air or a liquid through or over an aluminum heat sink surrounding the high-power transistors for each leg of the three-phase ac motor/generator assembly.

HV flywheel generator: Generator that accelerates a large flywheel rotor around electromagnets to store large amounts of electrical energy. It is also called a kinetic energy generator.

HV motor: A motor powered by electricity that is used to propel, or assist in propelling, a gas-electric hybrid vehicle.

HV motor-generator cables: Cables electrically connecting three-phase alternating current from the power control module to the motor-generator with each cable carrying a single phase of ac.

HV motor-generator cooling system: System that uses liquid coolant to prevent the traction motor from overheating in full-electric and hybrid gas-electric vehicles.

HV PCM cooling system: System that often uses the same electric water pump and circulated liquid coolant as a motor-generator and HV battery to cool the module.

HV PCM water jacket: Area formed between inner and outer housings surrounding the high-power, control circuit boards mounted on a heat sink (inner PCM housing contacting coolant).

HV power cable: Consists of all large-diameter, high-voltage conductors wrapped in orange plastic insulation that electrically connect the HV battery, HV power control module, and motor-generator.

HV power cable leakage: Can be discovered by measuring the cable's resistance to ground. A grounded ohmmeter should read infinite resistance with good insulation. Any resistance reading shows unwanted current leakage to ground.

HV power cable resistance: Measurement of current flow restriction that should read less than 0.001 ohm (1 milliohm) per 10 feet of cable. Add approximately 0.025 ohm per electrical connection.

hybrid air bag: Air bag used in hybrid vehicles that uses two methods to inflate the air bag: a small explosive charge and a pressurized gas cartridge.

hybrid air cooling system: System that uses an electric blower fan and a system of ducts to route cool passenger compartment air around the high-voltage battery pack.

hybrid battery cell: Individually sealed rechargeable battery containing a semi-solid electrolyte around positive and negative plates. Each nickel-metal hydride (NiMH) or lithium-ion cell generates about 1.2–1.6 volts dc.

hybrid battery pack: Several battery modules wired in series that generate high-voltage dc. The power control module converts battery pack voltage to ac or changes it to a higher or lower voltage.

hybrid brake: A form of regenerative braking. This electric braking system works with the conventional hydraulic brakes to slow the vehicle, while at the same time generating electricity to recharge the vehicle's HV battery.

hybrid control module: Electronic control circuit that measures driving conditions, voltages, and current loads to efficiently operate the motor-generator, HV PCM, and battery.

hybrid drive ready light: A light in a combination meter that blinks or glows to signify when the electric drive is engaged and the vehicle is ready to be driven.

hybrid electric vehicle (HEV): Vehicle that uses two different sources of propulsion to power the vehicle drive train.

hybrid ground fault interrupter: A device that continuously monitors a hybrid electric vehicle's system for any high-voltage loss into the metal frame of the vehicle. If detected, a warning light is activated, and the module de-energizes the main power relays to disconnect the battery pack from its electric drive circuit.

hybrid liquid cooling system: System that uses an electric water pump, small diameter hoses, and a separate radiator or heat exchanger to pull heat out of an HV battery, HV power control module, and motor-generator.

hybrid master warning light: A light in a combination meter that warns if there is a problem in any part of the gas-electric hybrid drive train.

hybrid power cable: Heavy-gage wire that transfers extremely high voltages to the components of a hybrid's electric drive system. The power cables are heavily insulated to prevent these voltages from shorting to ground.

hybrid power control module: Set of high-power circuits that manage the flow of electrical energy through a hybrid vehicle's electric drive train.

hybrid power display: A display in a combination meter that informs a driver of the hybrid drive operating conditions such as energy efficiency and battery life.

hybrid transmission: Automatic transmission in a hybrid vehicle modified with an electric drive motor-generator(s) for electric drive propulsion, high-voltage battery recharging, and regenerative braking.

hydra-booster: See *hydraulic booster*.

hydraulic booster: A power brake hydraulic booster that uses power steering pump pressure to help the driver apply the brake pedal. It uses fluid pressure, instead of vacuum, to help force the piston forward. It is also termed a hydra-booster or hydro-boost.

hydraulic brake: Type of brake that uses fluid pressure to actuate braking.

hydraulic circuit diagram: Diagram that shows the fluid passages and connections to components and parts within a hydraulic circuit.

hydraulic clutch release mechanism: Type of clutch release mechanism that uses a simple hydraulic circuit to transfer clutch pedal action to the clutch fork. The circuit includes a clutch cylinder, hydraulic line, and slave cylinder.

hydraulic four-wheel steering system: Type of four-wheel steering system that uses a

Copyright Goodheart-Willcox Co., Inc.

conventional power rack-and-pinion steering system up front. A rear power steering pump, which is driven by the differential, provides fluid pressure for a control valve that operates the rear steering system when a set road speed is reached.

hydraulic line: System of steel tubes and rubber hoses that contain and move high-pressure fluid within a hydraulic system.

hydraulic press: A machine that uses hydraulic pressure to produce tons of force for assembly or disassembly of pressed-together components.

hydraulic pressure modulation: Refers to the electro-hydraulic unit's ability to rapidly cycle pressure to the wheel cylinders or calipers on and off, preventing wheel lockup and skidding.

hydraulic system: Arrangement of pistons and tubing that use fluid pressure to transmit force from one part to another.

hydraulic tool: A tool powered by pressurized liquid.

hydraulic valve lifter: A valve lifter that uses hydraulic pressure from the engine's oil system to keep it in constant contact with both the camshaft and push rod/valve stem.

hydro-boost: See *hydraulic booster.*

hydrocarbon (HC): Highly flammable chemical mixture of about 12% hydrogen and 82% carbon that makes up the majority of crude oil. It is also an exhaust by-product of burned fossil fuels.

hydrogen: Highly flammable gas that could be a promising future automotive fuel due to its ideal burning characteristics, abundant availability, and harmless environmental by-products.

hydrometer: Tool used to measure the specific gravity (weight or density) of a liquid. A battery hydrometer finds the specific gravity of the electrolyte, which is an indication of the battery's state of charge.

hydrometer reading: Displayed in different ways depending on the type of hydrometer used. A fully charged battery should have a hydrometer reading of at least 1.265.

hydroplaning: A loss of control that occurs when a layer of water prevents a tire's tread from contacting the road surface.

hypoid gear: Gear used in applications where power flow must be diverted by some angle. Similar to spiral bevel gears except the driving pinion gear meshes with the ring gear below the centerline of the ring gear.

I

icon: Small pictures used on modern alignment equipment to help operate the equipment.

idle air control motor: Solenoid- or servo motor-operated air bypass valve that may be used to help control engine idle speed.

idle air control motor tester: Tool that energizes the solenoid or servo motor to check its effect on engine idle speed.

idle live reading: Typical circuit value with an engine running at curb idle speed and full operating temperature.

idler arm: Part of the parallelogram steering linkage attached to a vehicle frame opposite the pitman arm to prevent unwanted flexing of the center link.

idling: Term for an engine running while the vehicle is not in gear.

ignition coil: Device used to produce the high voltage needed to fire the spark plugs for ignition.

ignition coil open-circuit voltage: Maximum voltage potential of the ignition coil that ranges from 40,000–100,000 volts in late-model designs.

ignition control module (ICM): An "electronic switch" that turns the current flow through an ignition coil on and off based on data from the ECM and crankshaft and/or camshaft position sensors.

ignition lag: Time lapse between initial fuel injection and actual ignition (burning).

ignition load test: Test that measures spark plug firing voltages when engine speed is rapidly increased. It is also referred to as an acceleration test.

ignition lock mechanism: Device, normally located on the top, right-hand side of a steering column, that locks a vehicle ignition.

ignition supply voltage test: Test that measures the amount of voltage going to the positive terminal of the ignition coil(s).

ignition switch: Key-operated switch mounted in a steering column for connecting and disconnecting power to the ignition and electrical system. When turned to start, the ignition switch closes the starter relay to complete the circuit to the solenoid windings and on to the starter motor to crank the engine. It is also called a start switch.

ignition system: Components that produce a spark to ignite the air-fuel mixture in the engine.

ignition system supply voltage: Voltage that is fed to the ignition system by the battery, alternator, or HV PCM.

ignition timing: Relationship between the exact time a plug is fired and the position of the piston in terms of degrees of crankshaft rotation. It is also known as spark timing.

I-head engine: See *overhead valve engine.*

illuminated entry system: Turns on the interior lights when the vehicle door handle is moved or the door is opened. These systems can vary from simple to complex.

IM 240 test: Type of emissions test that is performed by state sponsored I/M programs. A vehicle is placed on a dyno and operated at real driving conditions while exhaust gas is sampled from the tailpipe.

impact driver: Tool that, when struck with a hammer, exerts a powerful turning and downward force to loosen extremely tight screws.

impact extension: Case-hardened steel extension that must be used with air and electric impact wrenches. It has a black matte finish and is thicker and much stronger than conventional chrome-plated extensions.

impact sensor: Sensor mounted in the front or side of the vehicle that tells the air bag control module that a collision has occurred.

impact socket: Case-hardened steel socket that must be used with air and electric impact wrenches. It has a black matte finish and is thicker and much stronger than conventional chrome-plated sockets.

impact wrench: Heavy-duty compressed-air wrench that provides a very fast means of installing or removing threaded fasteners. An impact wrench uses an air motor to produce a striking force to rotate a driving head. It is also called an air wrench.

impedance: Resistance to alternating current at a given frequency.

impeller: A wheel-like device that has fins cast into it. It is the driving fan that produces oil movement within a torque converter. It is also termed a converter pump.

impeller electric fuel pump: Pump that spins an impeller (fan blade) to produce centrifugal force. Fuel moving outward due to this force produces enough pressure to propel the fuel through the fuel lines.

improper range/performance failure: Specific type of computer system failure that occurs when a sensor or actuator produces values slightly lower or higher than normal.

improper wheel balance: A tire and wheel assembly with an uneven distribution of weight. If one side is heavier than the other, the tire will rotate incorrectly, causing tire and steering wheel vibration.

inboard CV joint: A constant velocity joint that can move in and out to compensate for changes in drive axle length as the wheels move in relation to the transaxle. It connects the inner stub shaft to the interconnecting shaft in a swing drive axle.

incandescent lightbulb: Bulb that generates light by sending current through a filament (usually tungsten resistance wire) inside a vacuum. This produces heat and the emission of light energy.

incorrect camber: Produces wear on one side of the tire tread.

incorrect shift point: Problem in an automatic transmission where the timing of a gear shift is delayed, rushed, or fails completely.

incorrect toe: Causes a feathered edge to form on the tire tread.

independent drive axle assembly: An axle assembly made of multiple shafts connected by a universal joint. The flexible nature of the assembly allows for smooth operation and transfer of power from the differential to the hubs and drive wheels of the vehicle.

independent shop: An automotive repair facility that is not affiliated with a vehicle manufacturer, retail store, or franchise operation.

independent suspension: A suspension system that allows each wheel to move up and down without influencing the other wheel on that axle.

indicated horsepower (ihp): Amount of power formed in an engine's combustion chambers, measured by a special pressure-sensing device.

indicator light: Light in a vehicle instrument cluster that indicates various system statuses and warns of a system problem.

Copyright Goodheart-Willcox Co., Inc.

indirect injection system: Type of fuel injection system that sprays fuel into an engine intake manifold or intake ports.

indirect tire pressure monitoring: Type of tire pressure monitoring system that relies on the anti-lock brake system wheel speed sensors, instead of separate sensors, to monitor wheel rotational speeds and tire pressure.

induction: The imparting of electricity to an object by passing it through magnetic fields.

inductive pickup: A test lead for a multimeter that is placed around a current-carrying wire to make an amperage reading by measuring the magnetic field around the wire.

inductive wire tracer: Instrument (consisting of a pulse generator and an inductive probe) that can be used to find internal breaks in wires and disconnected wires or terminals. As the pulse generator produces a low-voltage alternating current in the wiring, the inductive probe is moved along the wire. The tracer makes an audible beeping sound if the wire has continuity and is carrying the pulsing signal. A break in the wire or a poor connection causes the signal to stop or change tone.

inertia: Force that tends to keep stationary objects from moving and keeps moving objects in motion.

inertia ring: Part of a harmonic balancer that, along with the rubber ring it is positioned on, sets up a damping action on a crankshaft as it tries to twist and untwist.

inertia switch: Switch that can be used to block current flow to the electric fuel pump after a severe impact or collision. After a collision, a button on the inertia switch must be pressed before the electric pump will function again.

inertia switch circuit: Circuit that controls a switch that can be used to block current flow to the electric fuel pump after a severe impact or collision.

infinite resistance: Description of a circuit path that is not complete; current is blocked through the tested circuit or component. It is displayed on a digital multimeter as an ∞ (infinity) symbol.

inflatable door impact beam: An experimental automotive protective device that employs a powerful pyrotechnic charge that is used to expand the metal beam so it balloons out to a larger diameter. The larger beam can withstand more violent collisions.

inflatable seat belt: Seat belt that uses small air bags located in the shoulder harness straps.

infrared sensor: Sensor that sends out an invisible light beam from the front of a vehicle. In a collision avoidance system, when the beam hits an object and returns to the sensor, the computer interprets the information.

injection line: High-strength stainless steel tubing that carries fuel to each injector nozzle within a diesel fuel system.

injection-pressure test: Test that uses a pressure transducer (sensor) and scope to measure instantaneous pressure in fuel injection lines or a fuel rail.

injection pump: A high-pressure, mechanical pump. It is powered by the engine and forces fuel to the diesel injector under very-high pressure.

injection pump camshaft: Engine-powered rod that spins inside an inline diesel injection pump, moving its lobes against pump roller tappets to operate the pump plungers.

injection pump roller tappet: Spring-seated roller that rides against an injection pump camshaft to transfer the camshaft motion to pump plungers.

injection pump solenoid: Electronic device that controls injection timing and injection quantity with signals from a computer.

injection pump vent: Small passage in a diesel injection pump that allows fuel to return to the fuel tank.

injection timing: The relationship between injection of fuel and the positions of the engine's pistons.

injector balance test: Test that measures pressure drop and flow from fuel injectors.

injector body: Main section of a fuel injector, which houses its various parts and fuel passages.

injector leakage: Dripping or draining of fuel from a fuel injector. This problem points to a dirty injector nozzle or worn components.

injector maximum flow test: Test that fires each fuel injector for a predetermined amount of time while measuring flow through the injector with the injector pintle and nozzle held fully open.

injector nozzle: Spring-loaded valve that sprays fuel into an engine combustion chamber.

injector pressure chamber: Chamber machined into the inner cavity in an injector body around the tip of a diesel injector needle valve. Injection pump pressure forces fuel into this chamber to push the needle valve open.

injector pulse width: Shape of an electronic signal that determines the amount of time each fuel injector is energized and kept open to spray fuel into an engine.

injector spring: Spring fitted around a diesel injector needle valve that holds this valve in the normally closed position. Spring tension helps control injector opening pressure.

injector substitution: Simple way to verify a fuel injector problem by installing a good injector for the one being tested.

inline diesel injection pump: Type of diesel injection pump featuring plungers lined up in a row, similar to pistons in an inline engine. It can be used with all hydraulic or electro-hydraulic injectors.

inline engine: An engine with its cylinders arranged in a single straight row. Each cylinder is placed in a straight line parallel to the crankshaft.

inline pump plunger: Small piston inside an inline diesel injection pump that pushes on and pressurizes diesel fuel.

inner race: Steel cup or cone that rests on a spindle or drive axle shaft to serve as an inner surface for wheel bearing rotation.

inner stub shaft: Section of front-drive axle that is splined to side differential gears. It is connected to the interconnecting shaft through a universal joint.

inner tube: Soft, thin rubber liner tube fitted separately inside an older tire to accept air pressure to inflate the tire.

input: An electrical signal of a vehicle condition that is received and used by a computer.

input gear: Machined gear on a transmission input shaft that drives the forward gear on the countershaft assembly. A spur gear may be used for synchronizer engagement.

input shaft: A splined shaft that delivers power to a mechanism, such as the transmission input shaft delivering power to the transmission gears. It is also called a turbine shaft.

inspection and maintenance program: See *emissions testing program.*

inspection facility information section: Part of a vehicle inspection report that identifies the emission inspections facility and inspectors, as well as date and time of the test.

instrument cluster: Housing and clear plastic cover that holds most of the dash gauges, speedometer, and indicator lights. Digital instrument clusters do not use analog or needle gauges; but rather computer-driven numbers or graphic displays.

instrumentation electronic control module: A control module that reacts to signals from vehicle sensors, dash switches, and other ECMs to operate the digital or digital-analog displays in the dash.

insulated circuit resistance test: Test that uses a voltmeter to check for excessive resistance in an insulated, energized circuit.

insulating glove: Type of glove specially made to work on high-voltage components and cables. OSHA-approved lineman gloves or approved gloves with an insulation rating value of at least 1000 volts should be worn for hybrid electric vehicle service.

insulator: A substance that resists or stops the flow of electrons. Examples include air, glass, plastic, rubber, and porcelain. *Also,* a rubber bushing and metal insert that fits into a hole in a leaf spring to prevent rattles and noises.

intake air temperature (IAT) sensor: A sensor that uses a thermistor to measure the temperature of the air entering the engine. It is usually located on the air cleaner or on the engine air inlet duct to adjust air-fuel mixture. Cold air is denser than warm air, requiring more fuel for the proper air-fuel ratio.

intake camshaft phaser: Primarily increases engine power and torque by closely controlling airflow past intake valves and into cylinders.

intake manifold: Series of connecting tubes or housing between the throttle plate and the openings to the intake valves.

intake manifold gasket: Gasket that seals the joint between an intake manifold and a cylinder head.

intake manifold warpage: Condition in which an intake manifold's sealing surfaces are no longer flat.

Copyright Goodheart-Willcox Co., Inc.

intake port: Large passages in the cylinder head from the intake manifold runners to the combustion chambers through which air-fuel mixture enters the cylinders. *Also,* a port, or vent, in a brake master cylinder that allows fluid to enter the rear of the cylinder as the piston slides forward.

intake stroke: The portion of the piston's movement that is devoted to drawing the air-fuel mixture into the combustion chamber.

intake valve: Valve through which air and fuel is admitted to the cylinder.

integral carrier: Type of differential carrier that is constructed as one piece with the axle housing. A removable sheet metal or cast metal inspection cover is available to service the rear end components.

integral-piston power steering system: Power steering system that uses an integral power steering gearbox or hydraulic piston assembly machined into the rack housing.

integral power steering gearbox: Gearbox that contains a hydraulic piston assembly machined directly into the worm-type steering gearbox, along with a flow-direction valve.

integral valve guide: Valve guide that is machined through the cylinder head casting.

integral valve seat: Precisely machined face on a valve port opening in a cylinder head casting.

integral voltage regulator: Device that uses an electronic circuit to control alternator output by changing the amount of current flowing through the rotor's field windings. It is mounted inside or on the back of the alternator.

integrated ABS: Combines the power booster, master cylinder, and modulator units into one assembly. All these units are mounted together.

integrated circuit (IC): A single chip of semiconductor material that contains various electrical components in miniaturized form.

intercalation: Inside a rechargeable battery, the reversible embedding of protons and electrons in the porous electrode materials between the positive and negative battery plates.

interconnecting shaft: The center axle shaft in a front-wheel drive axle assembly that fits between the two universal joints and inner/outer stub shafts.

intercooler: An air-to-air or air-to-liquid heat exchanger mounted between a turbocharger/supercharger and a vehicle engine. Passing heated, charged air through an intercooler before entering an engine cools the air and increases engine power.

intercooler coolant: A mixture of 50% water and 50% antifreeze. A small reservoir is normally provided for servicing the coolant.

intercooler line: Metal or rubber line that carries coolant from an intercooler to an intercooler radiator and back to the intercooler.

intercooler pump: A small electric water pump that keeps coolant circulating through the cooling tubes and intercooler radiator.

intercooler radiator: A small heat exchanger for transferring heat from the intercooler coolant to the outside air.

interference angle: A 1/2° to 1° difference between the valve seat face angle and the angle of the valve face. This decreases the contact angle between the seat and the valve to speed up valve sealing during engine operation.

intermediate pipe: Steel tubing that carries exhaust between the catalytic converter and muffler.

intermediate section: Section of an oscilloscope pattern that shows voltage fluctuations after a spark plug stops firing but before the ignition control module allows current flow through the ignition coil. It is also referred to as the coil oscillations section.

intermittent: An event that occurs at varying intervals and/or under certain conditions.

intermittent fuel injection: Type of fuel injection in which injectors open and close regardless of intake valve positions.

intermittent problem: System malfunction that occurs infrequently, usually when certain conditions are met, such as temperature, humidity, vehicle operation, or in response to tests performed by a computer.

internal engine leak: Engine problem that can be represented by oil in a coolant reservoir tank.

internal lifter wear: When on a hydraulic lifter, wear prevents the lifter from pumping to take up valve train clearance.

internal oil leakage: Leaking oil within an engine. Burning engine oil will show up as blue smoke coming out an engine's exhaust.

International Automotive Technicians Network (iATN): An Internet website and community dedicated to automotive service technicians for assistance with vehicle diagnosis and repair problems.

interview: A meeting between a job candidate and an employer that allows the employer to more thoroughly question and examine the candidate's qualifications.

in-vehicle engine overhaul: Overhaul that can only be done when cylinder and crankshaft wear are within specifications and the oil pan and heads can be easily removed with the engine installed in the vehicle.

inverter circuit: Portion of the hybrid power control module that changes dc to ac and ac to dc.

ionization knock sensing system: A system used to detect knocking. In this system, the ECM prompts the ignition coil to send a low-voltage discharge across the spark plug gap immediately following combustion. Combustion quality affects the resistance across the plug gap by varying the degree of ionization in the gases between the plug electrodes.

isolation mode: An ABS operation mode whereby the ABS control module detects that a tire is starting to skid and energizes the modulator to isolate that hydraulic circuit from the other brake lines.

J

jack stand: An adjustable stand used to support an automobile that has been raised by a jack.

jet valve: Extra valve on an air jet combustion chamber that opens at low and idle engine speeds to inject an airstream to improve fuel mixing and combustion.

jounce: Term for the compression/bouncing movement of a coil spring.

jounce bumper: Blocks of hard rubber located directly beneath the upper spring seat to keep suspension system parts from contacting the frame or body when the car hits large bumps or holes.

jump start: Service procedure using jumper cables and another running vehicle to start a vehicle with a discharged (dead) 12-volt battery. One jumper cable is connected to the positive terminal on each battery. The other jumper cable is attached to the negative terminal of the charged battery and the frame (ground) of the dead vehicle, away from the battery. As the other vehicle runs, crank the ignition of the dead vehicle.

jumper wire: Short piece of insulated wire used to bypass electrical connections or devices to test operation. Most jumper wires have small alligator clips on each end.

junction block: An electrical block, usually located in an engine compartment. It contains fuses, circuit breakers, and relays to power high-amperage devices.

K

keep alive memory (KAM): A type of computer memory that stores changes in sensor values. It provides information to a computer's CPU so it can properly adjust signals to various output devices. It is sometimes referred to as adaptive strategy.

key: A small metal piece that fits into a groove partially cut into two parts to allow them to turn together.

keyless entry system: Device that allows a driver to unlock a vehicle's doors without using a key. The two basic types are remote and keypad-type keyless entry systems.

keyless entry tester: Device used to troubleshoot problems with the key chain sending unit and signal sensor of a vehicle's keyless entry system.

key-on/engine-off diagnostic: Diagnostics performed with the ignition key turned to the on position, but the engine not running.

key-on/engine-on diagnostic: Diagnostics performed with the engine running at full operating temperature.

keyway: A slot cut into a shaft, pulley, or hub that permits the insertion of a key.

kinetic energy generator: See *HV flywheel generator.*

kinetic energy recovery system (KERS): Fuel system design that captures kinetic energy generated during vehicle braking and stores the energy to assist in vehicle acceleration from a standstill. These types of systems use either a flywheel mechanism (mechanical) or a battery (electrical) to store the energy captured until it is needed.

Copyright Goodheart-Willcox Co., Inc.

knee bolster: See *knee diverter.*

knee diverter: Thick plastic panel formed into the lower part of a dash as a restraint device to protect a driver's and the front passengers' knees from being injured on the metal frame of the dash. It is also called a knee bolster.

knock sensor (KS): Engine sensor that detects preignition, detonation, and knocking.

L

lack of engine power: Condition that causes a vehicle to accelerate slowly due to inadequate torque or horsepower. Various problems could be at fault. It is also termed a sluggish engine.

lap belt: Part of the seat belt that extends across a person's lap.

lapped: For a set of gears, it is a machine process that involves meshing and spinning the gears together with abrasive compound on their teeth. It decreases operational noise and increases service life.

lapping stick: A rod with a suction cup on the end used to spin a valve on its valve seat when checking valve-to-seat contact.

lateral acceleration: The amount of side force, measured in units of gravity (g-force), a vehicle can handle before its tires lose traction and skid in a sharp turn.

lateral acceleration sensor: Stability control system sensor that measures how much side force is generated by a turn.

lateral control rod: See *track rod.*

lateral runout: A measure of in-and-out movement, or wobble. It is measured in the direction that is lengthwise to the centerline of the rotating object.

lazy O_2 sensor: Term for an oxygen sensor that will not alter its output signal fast enough to maintain an efficient air-fuel ratio.

leading edge: See *rising edge.*

leaf spring: Spring assembly that consists of a series of curved steel strips, or spring leaves, that are stacked and held together by a large spring clip. Smaller clips are used to help hold the leaves in position.

leaf spring windup: A condition that causes rear leaf springs to flex when driving or braking forces are applied to the suspension system. This spring distortion can cause unintended vehicle body movements.

leak-down rate: The amount of time it takes the pressure inside a hydraulic lifter to bleed out.

lean air-fuel mixture: Fuel mixture that contains a large amount of air compared to fuel.

lean burn oxygen sensor: Type of oxygen sensor that measures the oxygen content in the exhaust of lean-burn engines. This type of sensor can measure ratios as lean as 23:1.

lean trouble code: Diagnostic code set if an O_2 sensor detects high amounts of oxygen in engine exhaust.

L-head engine: See *flat head engine.*

lift: Device used to raise a vehicle during service and repair procedures. It is a permanently installed fixture in many automotive repair shops.

lifting fixture: Device that attaches to the engine hoist and is then bolted or positioned on the engine's lifting points to lift the engine from the engine bay.

light-emitting diode (LED): Special diode that lights when forward-biased. It, along with a photo diode, is used to produce an engine speed signal for the ignition system.

light-monitoring system: Safety system that turns on a warning light in the instrument panel when a headlight, brake light, or other light burns out.

lighting system: A system that provides illumination inside and outside of a vehicle.

lightweight spare tire: Type of spare tire constructed with a thin tread and sidewall. It is lighter, making it easier to lift and replace than most spares, but must be driven with caution.

like charge: Same charged electrical fields that repel each other.

limited-slip differential: A differential unit designed to provide superior traction by transferring the driving torque to the wheel with the best traction. It is extremely useful in wet or icy conditions.

limp-in mode: ECM operation mode that engages in case of total failure. It allows limited vehicle operation so the vehicle can be driven to a repair shop.

line boring: A precise machining operation that cuts a series of aligned holes through an engine block for crankshaft main bearings or camshaft bearings.

line honing: Straightening or truing misaligned main bearing bores by scratching abrasive stones against their surfaces.

liner: Thin, rubber layer of a modern tubeless tire that creates a leakproof membrane. It is bonded to the inside of the plies.

liner protrusion: See *sleeve protrusion.*

linkage steering system: Steering system that transmits the rotation of the steering wheel through a worm-type steering gearbox to the steering arms, which act on rods connected to the wheel assemblies.

liquefied petroleum gas (LPG): One of the lightest fractions of crude oil that is a gas at room temperature and pressure. LPG requires a special fuel system to meter it into the engine if used in automobiles.

liquid cooling system: Circulation of a heat-absorbing medium through engine passages, with the accumulated heat dissipated by further circulation through heat exchanger (radiator).

liquid crystal display (LCD): A device that has a fluid crystal material sandwiched between two sealed glass plates. This device can polarize light (make all the light waves vibrate in a single plane) to display numbers, letters, or other images.

liquid electrical tape: A liquid coating that, when it dries, creates a plastic or rubber-like substance that protects a conductor.

liquid-vapor separator: Valve above the main fuel tank used to keep liquid fuel from entering the EVAP system.

liter (L): Metric unit commonly used to refer to engine displacement. Measuring volume, one liter is equal to roughly 61.023 cubic inches.

load: Electric current-using device.

load at misfire: Readout of the load (as a percentage) when an engine misfire happened.

load conversion chart: Table used to determine how much current draw should be applied to a battery for a load test. It is usually provided with the load testing equipment to convert battery ratings to load test amps.

load tester: Device used to check the condition of a vehicle's battery, charging system, and starting system. It measures both system current and voltage while applying a load to the system.

load voltage: Voltage at the vehicle battery with the engine running and all electrical accessories on.

local interconnect network (LIN): A data bus system that is designed to work in conjunction with CAN.

location grid: A grid used to locate components or connections quickly on a large wiring diagram. It is an alphanumeric system marked off around the outside of a wiring diagram.

locking hub: Controllable components that transfer power from the front driving axles to the front driving wheels on a four-wheel-drive vehicle.

locking pliers: Handheld tool that, due to its strong clamping and locking ability, is helpful for removing fasteners with heads that are badly rusted, rounded off, or damaged.

locking steering wheel: When the ignition key is off, a steel pin slides into mesh with a slotted disc that is splined to the steering shaft so the steering wheel cannot be turned.

lockup torque converter: A torque converter with an internal clutch that locks the turbine to the impeller when the automatic transmission is in direct drive or overdrive.

long-short arm suspension: Suspension design that uses control arms of different lengths to keep the tires from tilting with suspension action.

long-term fuel trim: Term for a permanent adjustment of injector pulse width to compensate for altered engine operating parameters.

longitudinal: Lengthwise; term used to identify an engine mounted with its centerline parallel to the centerline of the vehicle.

longitudinally split: Type of front to rear brake system in which one master cylinder piston operates the front wheel brake assemblies and the other operates the rear brake assemblies.

low back pressure: Low resistance, ideal condition in a vehicle exhaust system that increases engine power and gas mileage.

low boost pressure: Condition in a turbocharged/supercharged system caused by various issues that results in a lack of engine power.

low brake pedal: A brake pedal that travels too far toward the floor before fully engaging the brakes.

low engine compression: Condition in which an engine is operating on cylinders that are providing insufficient compression pressure.

Copyright Goodheart-Willcox Co., Inc.

low fluid level: Fluid in a transmission below normal standards. A low fluid level can cause air to enter the system, leading to engagement and shifting problems as the oil pump builds pressure too slowly.
low fluid warning light switch: When mounted in the brake fluid reservoir, the switch contacts close when the brake fluid falls below a certain point.
low impedance fuel injector: Fuel injector that should have an internal resistance of about 0.5 to 3 ohms.
low-input failure: Specific type of computer system failure that produces voltage, current, or signal frequency below normal operating parameters.
low oil pressure: Condition when oil is not adequately pressurized to reach all lubrication areas. It is indicated when the oil indicator light glows, the oil gauge reads low, or the engine lifters or bearings rattle and knock from lack of lubrication.
low oil pressure safety circuit: Circuit designed to shut off the electric fuel pump if the engine is operating on low oil pressure or the oil pump fails.
low-pressure cutout switch: In an A/C system, shuts off the compressor when system pressure drops below a certain point to prevent compressor damage.
low side: Part of an A/C system that consists of the parts between the flow-control restriction and the inlet of the compressor. It is also called the suction side.
low-time: See *off-time.*
lower spring seat: A lower mount on a strut assembly formed around the shock body into which a coil spring fits.
lubrication service: Maintenance service of checking, adding, or replacing vehicle fluids. It also includes greasing vehicle components for proper usage and examining for problems.
lubrication system: Method of distributing lubricant (oil) to moving parts to minimize friction.
lubricator: Device that is part of a compressed-air system used to introduce oil into the airstream for improved air tool life.
lug bolt: Threaded bolt that screws into a hole in the axle hub or flange to hold the wheel.
lug nut: Fastener nut threaded on a lug stud and tightened to hold a wheel on an axle hub.
lug nut torque: Tightening force specification for lug nuts that attach a tire and wheel assembly to an axle hub.
lug stud: Special stud pressed through the back of an axle hub or flange that accepts the lug nut.

M

machine screw: Small screw that resembles a bolt. It is used on various machine parts needing just a light clamping force.
MacPherson strut suspension: Suspension system that uses only one control arm and a strut for each wheel assembly.
magnafluxing: Testing procedure that uses a magnet and metal powder to find cracks in cast iron parts.
magnet-and-ball sensor: Impact sensor that uses a small permanent magnet to hold a steel ball away from the electrical contacts in the sensor.
magnetic clutch: Used to engage and disengage the air conditioning system compressor.
magnetic field: Invisible lines of force between the poles of a permanent magnet and around the outside of current-carrying wire.
magnetism: Invisible lines of atomic force that attract or repel ferrous metals through space, air, or solid matter.
mag wheel: Nickname for a wheel constructed of aluminum or magnesium.
main bearing bore: Holes machined in the bottom of an engine block to hold the crankshaft.
main bearing cap: Metal caps fastened to the bottom of a cylinder block to form one-half of the main bore. They hold the crankshaft and main bearings in place.
main bearing knock: Deep, dull rapping noise from a crankshaft moving excessively inside a cylinder block. It is caused by bearing wear, and possibly journal wear.
main oil galleries: Large oil passages through the center or side of a cylinder block casting that connect to small oil galleries within an engine.
main shaft: See *manual transmission output shaft.*
main shaft gear: See *output shaft gear.*
maintenance-free battery: Type of lead-acid battery that does not have removable filler caps. Calcium in the battery plates reduces the battery gases and eliminates the need for water to be periodically added to the electrolyte.
main thrust bearing: Flanged version of a main bearing, designed to limit crankshaft end play.
main wiring diagram: A large diagram that contains symbols for all major wiring and electric/electronic components on a vehicle. It may vary depending on the manufacturer.
malfunction indicator light (MIL): Amber-colored light in an instrument cluster, commonly called a Check Engine or Service Engine Soon light, used to indicate that a problem exists in a vehicle's computer control system. It is also a generalized term used for any instrument cluster light used to indicate a problem in a system.
manifold absolute pressure (MAP) sensor: Sensor that monitors manifold pressure by producing an electric signal proportional to the pressure or vacuum inside an engine intake manifold. Manifold pressure is an excellent indicator of engine load.
manifold runner: Internal passages made in an intake manifold to carry either the air-fuel mixture or air to the cylinder head ports.
manual air bag deployment: Deploying an air bag by connecting a voltage source to the air bag module wires to "fire" the air bag.
manual bleeding: Process of using master cylinder pressure to force fluid and trapped air out of a brake system.
manual locking hub: Type of locking hub in a four-wheel-drive vehicle that requires the driver to turn a latch on the hub to lock it into four-wheel drive.
manual suspension leveling system: Switch-activated system that uses air shocks and an electric compressor to change vehicle suspension height based on load weight.
manual tilt steering column: Steering column that uses a hand lever on the column to unlock a flex joint so the wheel can be moved up or down.
manual transaxle: Combination of a manual transmission and a differential assembly. The gears are operated with shift forks, similar to those in a rear-wheel-drive manual transmission, controlled by the driver with a gearshift lever. Different combinations of gears are selected to obtain the desired gear ratios.
manual transaxle clutch: Clutch that resembles the clutch used with a manual transmission for a rear-wheel-drive vehicle. It uses a friction disc and a spring-loaded pressure plate bolted to a heavy flywheel.
manual transaxle input shaft: Shaft that receives power from the engine through the clutch and transmits it with gear meshing on the output shaft.
manual transaxle output shaft: Shaft that contains gears that mate with the input shaft. This rotating shaft, which holds output gears and synchronizers, delivers power to the transaxle differential.
manual transaxle transmission: Manual transmission assembly that connects to a vehicle transaxle. It provides several (usually four or five) forward gear ratios, a reverse gear, and sometimes an overdrive gear.
manual transmission: System with several gear ratios to allow for efficient operation under various conditions. The vehicle operator makes the gear selection decisions. Transmission gears and gear synchronizers are moved in and out of engagement by shift forks.
manual transmission case: Aluminum or cast iron housing that encloses the transmission shafts, gears, synchronizers, shift forks, linkage, and lubricating oil. In some designs, it is combined with the clutch housing.
manual transmission gear sensor: Sensor that monitors the position of reverse, neutral, and all forward gear ratios within a gearbox. It is a safety switch used if gears fail to shift properly. It is also known as a switching sensor.
manual transmission input shaft: Long shaft that extends from the rear of the engine crankshaft to the inside of the transmission case. It supports the clutch disc, holds it in proper alignment with the other clutch components, and transmits rotation of the clutch disc into the transmission. It is also called the clutch shaft.

Copyright Goodheart-Willcox Co., Inc.

manual transmission output shaft: A splined, rotating shaft that delivers power to the drive shaft assembly and holds the output gears and synchronizers. It is also called the main shaft.

manual transmission pressure sensor: Sensor in an automated manual transmission that measures the pressure of the hydraulic fluid used to operate wet clutches that transfer power to different shafts and gears.

manual transmission shift solenoid: Computer-controlled solenoid that operates a metal plunger to slide or hydraulically move synchronizers into position. With wet clutches, it opens hydraulic spool valves to control oil flow.

manual transmission synchronizer: Assembly of hub, sleeve, and other components that locks the selected output gear to the output shaft to transmit power. It permits meshing of gears without grinding.

manual valve: Valve controlled by the shift mechanism and linkage that routes oil pressure to the correct transmission components based on the selected gear.

mass airflow (MAF) sensor: A digital sensor mounted on or near the engine intake manifold that produces an ac signal that changes in frequency as airflow into the engine changes.

mast: Rod mounted on a vehicle body that serves as an antenna.

master cylinder: A hydraulic piston-type pump that stores brake fluid and develops pressure for a brake system.

master cylinder filling tool: A tool used to automatically keep the master cylinder fluid reservoir full of brake fluid while bleeding or flushing.

master cylinder reservoir: Stores an extra supply of brake fluid.

master technician: Technician with extensive experience and knowledge of all specialized areas of automotive technology. He/she can diagnose, service, and repair each vehicle system.

matter: Anything that occupies space and has mass, or weight.

maximum inflation pressure: Tire marking that tells the highest air pressure that should be pumped into the tire.

maximum load rating: Tire marking that indicates the amount of weight the tire can carry at the recommended inflation pressure.

measuring system: A set of standardized units used for measurement.

mechanical efficiency: A measurement of mechanical friction; determined by the difference between brake horsepower (bhp) to indicated horsepower (ihp). Mechanical efficiency of 70–80% is normal.

mechanical four-wheel steering system: Type of four-wheel steering system that uses a special front rack-and-pinion gearbox with a transfer box. A shaft, controlled by the transfer box, extends back to a rear rack to turn the rear wheels.

mechanical fuel pump: Fuel pump mounted on an engine. Found in all direct injection engines, an eccentric lobe on the engine crankshaft powers the pump, pushing the pumping plunger into the pump to build pressure.

mechanical lifter: Solid lifter used in some older vehicles that transfers camshaft lobe action to the push rod. It must be adjusted periodically.

mechanical oil pump: Mechanical pump that provides hydraulic pressure for clutch application in an electro-hydraulic differential.

mechanical speedometer: Uses plastic transmission/transaxle drive gears, a metal speedometer cable, a cable housing, and a mechanical speedometer head to convey vehicle speed.

media blasting: System that uses compressed air to blast small, abrasive particles against a surface. It can remove paint, carbon, and other dry deposits from parts.

memory saver: Device that temporarily supplies enough power to prevent stored memory loss within the clock, stereo, and computer when a vehicle battery is disconnected.

memory seat: Type of seat that is connected to a computer and remembers the position of the seat, as dictated by the driver. The computer can usually store 2 or 3 driver settings.

memory tilt wheel: A steering wheel that uses a tilt control module, sensor, and motor to automatically retain and move the steering column to a driver's preprogrammed position with the press of a button.

metal additive: Tiny metal particles, commonly zinc or titanium, added to motor oil to reduce part wear by coating internal engine parts.

metering valve: Valve designed to equalize braking action at each wheel during light brake applications. A metering valve is used on vehicles with front-wheel disc brakes and rear-wheel drum brakes.

methanol: See *methyl alcohol*.

methyl alcohol: A colorless, poisonous, and very flammable liquid made out of wood chips, petroleum, garbage, and animal manure. It is also called wood alcohol or methanol.

metric (SI) measuring system: A system of measurement used nearly worldwide that operates with a power of 10 for all basic measurement units.

metric rule: A straightedge scale that has numbered lines representing millimeters. Each numbered line usually equals 10 mm, or 1 centimeter.

metric wire size: The cross-sectional area of a wire in square millimeters (mm^2). Unlike AWG gage numbers, metric wire sizes increase as the diameter of the wire increases.

micrometer: Tool capable of making small measurements accurate to one ten-thousandth of an inch (.0001") or one thousandth of a millimeter (0.001 mm).

micron: Unit of measure for millionths of an inch.

mid-engine drive train: Rear-wheel drive configuration with the engine located right behind the driver's seat with a transaxle mounted behind it. Equal weight is distributed to each tire for high cornering capabilities.

mil: Unit of measure for wire diameters. It equals 0.001 inch.

mild hybrid: Type of gas-electric hybrid vehicle that is propelled by an internal combustion engine only. The engine shuts down whenever the vehicle comes to a stop. An HV starter-alternator is used to restart and assist the engine during acceleration. Also called an assist hybrid.

milky transmission fluid: A white or nontransparent pink-colored transmission fluid. It is commonly caused by engine coolant mixing with transmission fluid.

Miller-cycle engine: Engine designed with a shorter compression stroke and a longer power stroke to increase efficiency. Commonly, a supercharger is needed to pressurize the intake manifold and block airflow as the intake valve remains open longer to delay compression.

mini catalytic converter: A very small converter placed close to an engine exhaust manifold. It heats up quickly to reduce emissions during engine warm-up.

misfire code: Scan tool readout that shows the engine has failed to ignite and burn its air-fuel mixture properly.

misfire data: Information stored in the computer indicating which cylinders are misfiring and how often.

misfire data value: Values collected by a scan tool indicating something is causing an engine cylinder not to fire.

misfire failure: Number of times an engine cylinder has failed to fire.

misfire history: Record of the number of times an engine cylinder has failed to fire.

misfire pass: Record that shows the number of times an engine cylinder has not misfired.

misfire rev. status: Misfire data that shows real misfires and rejected misfires (false data caused by rough road or other cause).

misfiring: Failure of one or more cylinders to fire and produce normal combustion power.

misfiring cylinder: Readout displaying the primary misfiring cylinder and the secondary misfiring cylinder by cylinder number.

mode switch: Dash-mounted switch that allows a driver to choose the desired shock action or ride stiffness and sometimes ride height in electronic suspension systems.

modified strut suspension: Type of suspension that has a coil spring mounted on top of the lower control arm, not around the strut.

molded hose: Hose manufactured in a special shape, with bends specific to an exact year and make of car in order to clear certain parts.

molecule: A group of two or more atoms joined together by a chemical bond.

monitor: Commonly a liquid crystal or plasma display screen that provides various graphic information from a mapping system, stereo, climate control, and other systems for the driver and passengers.

Copyright Goodheart-Willcox Co., Inc.

motor-generator: Device that functions as both a powerful traction motor and as a high-energy alternator in a hybrid vehicle's power train.
motor-generator clutch: Clutch that engages its armature shaft to and from the engine crankshaft and the transmission shaft in a hybrid vehicle for different operations.
motor-generator coolant fitting: Fitting that allows a rubber hose to be clamped around the hose for a leakproof antifreeze connection.
motor-generator coolant hose: Hose that carries cooled coolant to, and heated coolant from, the motor-generator water jackets. Another hose creates a connection to the electric coolant pump or engine water pump.
motor-generator cooling system: System that removes excess heat from the stator housing and windings by the circulation of coolant through its outer housing.
motor-generator water jacket: Chambers machined inside the stator housing during manufacture that carry coolant to transfer heat away from the motor-generator.
motor-generator water pump: An electric coolant pump mounted between the system radiator and the stator housing that circulates coolant through the housing.
motor oil: See *engine oil.*
motor vehicle emission: Burned and unburned pollutant produced by car, truck, bus, and motorcycle engines and their fuel systems.
movable pole shoe starting motor: Starting motor that, when activated, pulls a pole shoe toward its armature with magnetic force, thus moving a drive yolk to slide the pinion gear to mesh with the ring gear.
muffler: A chambered unit attached to a pipe or hose that dampens pressure pulsations to deaden noise. On most vehicle exhaust systems, it is installed after the catalytic converter.
multi-cylinder engine: Engines that have more than one piston and cylinder. Automotive engines are classified as multi-cylinder engines.
multifunction switch: Switch capable of controlling several circuits. For example, headlights (bright and dim circuits) and turn lights simultaneously.
multimeter: Electrical test meter that can be used to test for voltage, current, or resistance. It is also referred to as a volt-ohm-ammeter or VOM.
multiple disc clutch: A clutch assembly that contains several clutch discs in its construction.
multiple discharge ignition system: Ignition system that fires the spark plugs more than once during each power stroke.
multiplexing: A method of using one communications path to carry two or more signals simultaneously.
multiplication: Arithmetic process in which the same number is added together a specific number of times.
multiport injection system: Type of indirect fuel injection system featuring a fuel injector mounted in each engine cylinder intake port.
multiviscosity oil: An engine oil that can exhibit different viscosity characteristics when heated or cooled.
mushroom valve: See *poppet valve.*
mushrooming: Condition where valve tips have been hammered larger by the action of the rocker arms.
mushy shift: Term for a gear shift in an automatic transmission that happens too slowly, causing the vehicle to feel sluggish.

N

narrow band oxygen sensor: Category of oxygen sensor that can only measure combustion efficiency near stoichiometric (chemically correct). Its output voltage toggles to show either a rich or lean condition.
National Institute for Automotive Service Excellence (ASE): A nonprofit organization formed to promote high standards of automotive service and repair through the voluntary testing and certification of technicians.
navigation system: System using the United States' satellite global positioning system to display the geographic location of a vehicle. Advanced systems can give other useful information: traffic information, roadwork, parking lot openings, miles to destination, turnoffs, etc.
negative battery cable: Cable that is normally black and connects to ground on the engine block or frame.
negative camber: The tops of the wheels tilt inward when viewed from the front.
negative caster: Tilts the top of the steering knuckle toward the front of the vehicle.
negative charge: An atom is said to have a positive charge if it holds excess electrons.
negative post: Battery post marked in black or green and with a negative (–) symbol. It is smaller than the positive battery post.
net horsepower: Maximum horsepower at the flywheel with all engine-driven accessories in use.
neutral safety switch: Switch wired into the circuit of the 12-volt starter solenoid that prevents the engine from cranking when the transmission is in drive or reverse.
neutral safety switch adjustment: Switch tightening or replacement needed when an engine will not crank with the shift selector in the *Park* position.
neutral steering: Ideal vehicle steering condition in which all four wheels have equal traction in turns.
neutron: One of the components of the nucleus of the atom; has no charge.
night vision system: An automotive security feature that uses an infrared camera and monitor system to help the driver's view in fog, snow, rain, and other vision-impairing atmospheric conditions.
no brake pedal: A dangerous condition in which the brake pedal moves to the floor with no braking action.
no-crank problem: Engine problem in which the crankshaft fails to rotate as the ignition key or starter button is activated.
noid light: Special test light used for checking electronic fuel injector feed circuits for battery power.
noise suppressor: Capacitor that absorbs voltage fluctuations in a vehicle's electrical system to reduce noise.
no-load voltage: Voltage at the battery with the engine running and the electrical accessories off.
nonadjustable rocker arm: Valve rocker arm that offers no means of changing valve lash/clearance.
nonhunting gearset: Term for a gearset that meshes the same ring and pinion gear teeth over and over during each revolution of the ring gear.
nonindependent suspension: Type of suspension that has both the right and left wheels attached to the same solid, inflexible axle, causing movement on one side to affect the other.
nonintegrated ABS: A conventional booster and master cylinder are used with a separate electro-hydraulic modulator.
non-resistor spark plug: A spark plug that has a center electrode that is one piece of metal rod.
nonthreaded fastener: A device, such as a snap ring, used to hold, or fasten, parts together without the use of threads.
non-vented fuel tank cap: Cap that prevents fuel vapors from entering the atmosphere through the tank's filler neck.
normal combustion: Term for efficient internal combustion within an engine that is a primary factor in maximizing fuel economy, engine power, and engine service life as well as lowering emissions.
normally aspirated engine: Engine that uses atmospheric pressure, not a turbocharger or supercharger, to force air into the engine. It is also called an atmospheric engine.
no-start problem: The engine is turned over by the starter, but fails to fire and run on its own power.
NPN transistor: A transistor that has two N-type semiconductors and one P-type semiconductor bonded together.
N-type semiconductor: A semiconductor that is doped so that it has excess electrons.
nucleus: The center of an atom.
nut: A fastener with internal threads to thread onto a bolt or stud and, commonly, a six-sided outer shape.
nut lock: Thin, slotted nut that fits over a spindle adjusting nut to secure the hub parts on an axle shaft.

O

O_2 sensor: See *oxygen sensor.*
OBD II drive cycle: Predetermined routine of acceleration, deceleration, and stops that allows the ECM to reset its emissions monitoring. It is usually performed after ECM replacement or before some emissions tests.
Occupational Safety and Health Administration (OSHA): A federal agency that gives general guidelines and rules for employee safety and the safe operation of work sites.

Copyright Goodheart-Willcox Co., Inc.

octane enhancer: Alcohol made up of hydrogen, carbon, and oxygen that is used as a gasoline blending component to increase octane levels and reduce engine knock. It is also called an oxygenate.

octane rating: Numerical measurement of gasoline's ability to resist knock or ping. The higher the octane rating is for a fuel, the greater its ability to resist knock or ping.

odometer chip: Miniaturized circuit that stores mileage of the vehicle.

off-car balancer: Machine that spins a wheel and tire assembly, after it is removed from a vehicle, to determine where the wheel needs balancing.

off-time: Oscilloscope reading where a square waveform stays on zero volts. It is also called low-time.

ohm (Ω): Unit of measurement for resistance to the flow of electric current in a given unit or circuit.

ohmmeter: An electrical instrument used to measure the amount of resistance in a given unit or circuit.

Ohm's law: Formula for computing unknown voltage, resistance, or current in a circuit by using two known factors to find the unknown value.

oil additive: Increases the protective properties of mineral, vegetable, or synthetic motor oil.

oil-air separator: Device that makes oil vapors condense and flow back into an oil pan.

oil burn test: Test to determine if water is present in engine oil. Hold a lit match or lighter flame against oil on a dipstick. If there is even a slight amount of moisture in the oil, the burning oil will make a "cracking and popping sound."

oil change interval: Manufacturer specified maximum number of miles (or kilometers) a vehicle can be driven between oil changes.

oil clearance: Small space between moving engine parts for the lubricating oil film. It is also called bearing clearance.

oil cooler: An air- or liquid-cooled device used to remove excess heat from the engine or transmission oil.

oil dye: Fluorescent dye sometimes added to engine oil when checking for external oil leaks.

oil filter: A filter element installed on the engine. It filters dirt and foreign debris from the oil entering an engine.

oil foaming: Problem of air bubbles forming in the engine oil, which reduces the oil's lubricating ability, caused by overfilling the engine oil.

oil gallery: Cast or drilled passageway or pipe in an engine. A gallery carries oil from one part of an engine to another.

oil level sensor: Float-variable resistance or optical-type sensor mounted in a vehicle oil pan that registers the actual quantity of oil in the engine.

oil pan: Metal or plastic pan located on the bottom of an engine or transmission. It acts as a reservoir for oil or fluid.

oil pan baffle: Sheet metal panel used to keep oil from splashing up on a spinning crankshaft and oil foaming.

oil pickup: Tube and screen that connects to the oil pump and extends to the bottom of the oil pan to pick up oil.

oil pressure gauge: A dash-mounted instrument that provides oil pressure readings in pounds per square inch or in kilopascals.

oil pressure indicator: Warning light on control panel to alert driver to low pressure situation.

oil pressure sending unit: Device that uses a variable resistor to communicate vehicle oil pressure to a computer and operate an oil pressure gauge.

oil pressure switch: Switch opened and closed by oil pressure so that it can operate the dash indicator light and shut off the fuel pump to prevent engine damage if the oil pressure is low.

oil pressure test: Test that uses a pressure gauge to measure the actual pressure in an engine.

oil pump: Device for forcing oil under pressure to the points where lubrication is needed.

oil ring: The bottom piston ring, which scrapes oil off the engine cylinder walls.

oil service rating: Identification of type of service for which an oil is suited.

oil slinger: Washer-shaped part mounted on a crankshaft sprocket to throw oil onto a timing chain during operation.

oil spurt hole: Small hole drilled in a connecting rod for improved cylinder lubrication.

oil viscosity: A measure of the oil's thickness or ability to flow. It is also referred to as oil weight.

oil weight: See *oil viscosity.*

on-board diagnostics: Term for a vehicle computer's ability to analyze the operation of its circuits and to output data identifying any problems found.

on-board diagnostics generation one (OBD I): Classification referring to any computer control system installed on vehicles built prior to 1996.

on-board diagnostics generation two (OBD II): Enhanced diagnostic system required on 1996 and newer vehicles. Protocol also called for standardization of codes, data link connectors, and terminology.

one-channel ABS: ABS channel that normally operates the rear wheel brakes together.

one-way clutch: See *overrunning clutch.*

one-wire circuit: See *frame-ground circuit.*

on-time: Oscilloscope reading where a square waveform stays at maximum voltage. It is also called high-time.

open circuit: Electrical circuit with a gap or break in continuity so that current cannot flow.

open circuit voltage: The voltage between a two-terminal device without a load connected. Each battery cell has an open circuit voltage of 2.1 volts, giving a series-wired automotive six-cell battery a 12.6 open circuit voltage.

open cooling system: Cooling system that does not use a recovery tank. The overflow tube is not connected to a coolant reservoir, and excess coolant leaks onto the ground. This system has been replaced on automobiles by closed cooling systems.

open differential: A type of differential that, at all times, provides equal amount of torque to both driving wheels. If one wheel loses traction, the opposite wheel will not have enough torque to propel the vehicle.

open diode: A diode that has a high (infinite) resistance in both directions.

open loop: In reference to an electronic fuel injection system, an ECM uses preprogrammed information instead of exhaust gas content to determine efficient air-fuel mixture.

operating parameter: An acceptable maximum or minimum electrical value saved in permanent computer memory chips.

opposed engine: An engine with cylinders lying flat or horizontal on either side of the crankshaft. It is also termed a pancake engine or boxer engine.

optional wiring: Wiring provided in a circuit that may not be in use.

orifice tube: See *expansion tube.*

O-ring valve seal: A small, round rubber seal that fits into an extra groove cut in a valve stem. It seals the gap between the valve retainer and valve stem.

oscillation: A compression-extension movement of a spring that uses up the energy that was present in the compressed spring.

oscilloscope: Diagnostic instrument that displays line patterns that relate voltages to time. It is commonly called a scope.

other sensors: Parts of a stability control system that gives the ECM information about the driver's actions and the resulting vehicle motion.

outboard CV joint: A constant velocity joint that connects the interconnecting shaft to the outer stub shaft in a swing drive axle. It transfers power from the axle shaft to the wheel hub assembly. The outboard CV joint is usually a nonsliding joint.

outer drive axle: Stub axle shaft that extends through the bearings and is splined to the wheel hub.

outer race: Steel cup or cone pressed into a hub, steering knuckle, or bearing support to serve as an outer surface for wheel bearing rotation.

outer stub shaft: In a front-wheel drive vehicle, the short shaft connecting the outer universal joint and the front wheel hub.

output: Computer-produced electrical signals that are sent from a computer after processing input data.

output shaft: Splined steel shaft that transfers rotating torque out of a transmission to the rest of the transmission driveline. It is also termed the main shaft.

output shaft gear: Gear attached to a transmission output shaft that transfers the motion from the countershaft gear it contacts to the output shaft. It is also called a main shaft gear.

Copyright Goodheart-Willcox Co., Inc.

outside work area: A designated area adjacent to an auto repair shop's overhead service doors that, in good weather, can be used as an open-air repair station.
over-advanced ignition timing: Occurs when the ignition spark happens too soon before the manufacturer's specified position of the piston during the combustion stroke. This causes the engine to suffer from spark knock, or ping, caused by abnormal combustion.
overboost: Term for too much supercharger boost to an engine.
overbore limit: Maximum amount that a block should be bored oversize without resulting in cylinder walls that are too thin.
overcharging: Problem that occurs when excess current is forced through a battery.
overcooling: Cooling system problem that occurs when an engine fails to reach full operating temperature, causing poor or sluggish engine performance.
overdrive ratio: An arrangement of transmission gears that results in the driven shaft turning more revolutions than the driving shaft, lessening torque output.
overhead cam (OHC) engine: Engine with camshaft(s) located in the top of the cylinder head. Push rods are eliminated and valves can be angled for improved engine performance.
overhead cam follower: A valve lifter fitted in a bore machined in a cylinder head directly between a camshaft and valve stem. Its clearance can be manually adjusted.
overhead valve (OHV) engine: Engine in which intake and exhaust valves are in the cylinder head. It is also called an I-head engine.
overheating: Cooling system problem that occurs when an engine operating temperature is too high, warning light is on, temperature gauge shows hot, or coolant and steam blow out of the overflow.
overinflation: Term for high air pressure within a tire, which pushes the center tread against the road but lifts to outer tread edges.
overrunning clutch: Mechanism that engages and locks a pinion gear in one direction when the armature is driving the clutch. When the engine starts, the clutch releases the pinion gear, allowing the gear to spin freely. It is also referred to as a one-way clutch.
oversteer: A vehicle steering issue in which the rear tires lose traction and slide sideways but the front tires retain traction as the vehicle goes through a corner. Controlled oversteer through a corner is known as drifting.
owner's manual: Booklet provided by the vehicle manufacturer to the purchaser of a new vehicle containing basic automotive and maintenance information about the vehicle.
oxides of nitrogen (NO_x): Undesirable compounds of nitrogen and oxygen in exhaust gases. They are usually produced when combustion chamber temperatures are excessively high.
oxyacetylene torch: Type of torch used to heat, cut, weld, or braze metal parts. The oxyacetylene setup includes an oxygen tank, an acetylene tank, pressure regulators, hoses, and a handheld torch.
oxygenate: See *octane enhancer.*
oxygenated gasoline: Reformulated gasoline containing additional oxygen sold in areas where ozone reduction is necessary.
oxygen sensor (O_2S): Exhaust sensor that measures the oxygen content in an engine's exhaust gases as a means of checking combustion efficiency. It is also called an exhaust gas sensor or O_2 sensor.
oxygen sensor contamination: Substances including leaded fuel, silicone, and carbon that damage and shorten the life of a vehicle oxygen sensor.
oxygen sensor monitoring: ECM tests to the primary and secondary oxygen sensors for abnormal voltage, slow response times, and similar problems.
oxygen sensor output voltage: Voltage output should cycle up and down from about 0.2–0.8 volts (200–800 mV). A 0.2 volt or low reading would show a lean air-fuel ratio and a 0.8 volt or high reading would show a richer condition.
oxygen sensor position: In a vehicle, oxygen sensor positions are assigned a number based on its location and order in relation to the engine's banks.
oxygen sensor signal generator: Tool for sending a false 200–800 mV signal to an engine control module for testing purposes.

P

pad-wear sensor: A metal tab on the brake pad that informs the driver of worn brake pad linings. The wear sensor tab emits a loud squeal or squeak when it scrapes against the brake disc.
pancake combustion chamber: Older, less common combustion chamber design with valve heads nearly parallel with the top of the piston.
parade pattern: Oscilloscope reading that lines up waveforms side by side across the screen. It is also called a display pattern.
paraffin: Wax substance that is found in diesel fuel.
parallel circuit: An electrical circuit that has more than one path for current.
parallel communication: Means of computer network communication that involves the use of several wires to exchange multiple bits of data simultaneously.
parallel hybrid: Gas-electric hybrid vehicle that uses both the internal combustion engine and the motor-generator to apply mechanical torque to the drive train.
parallel wire: Wire that has two or more individually insulated conductors or wires molded into one flat or round body of multicolor insulation.
parallelogram steering linkage: A steering linkage using two tie-rod assemblies connected to a long center link. The link is supported on one end by an idler arm and the other end is attached to a pitman arm. The two sides of the linkage run parallel and are equal in length, characteristics that give the linkage its name.
parasitic load: Any electric circuit draw present when the engine and all electrical devices are shut off. Circuits requiring small currents while the engine is not running (clock, ECMs, etc.) are included.
park assist tester: Device used to troubleshoot the output from a laser at the rear of the vehicle in a park assist system.
parking brake: See *emergency brake.*
parking pawl: A latch that locks the transmission output shaft so that the vehicle will not roll when the gear shift lever is in the *Park* position.
part: The smallest removable item on a vehicle. A part can also be referred to as a component.
part warpage: Condition in which the sealing surfaces on a part are not flat and therefore will not seal properly.
partially counterweighted crankshaft: Crankshaft with weights formed opposite the rod journals in the center portion of the shaft only.
particulate: Solid particle of soot and other substances that results from combustion.
passenger-side air bag: Air bag that deploys from the right side of the dash.
passive restraint system: A restraint system that operates without driver or passenger activation. Air bags and automatic seat belts are passive restraint systems.
passive sensor: A sensor that changes an externally produced signal, but does not generate its own voltage.
PCV valve: Positive crankcase ventilation system flow control valve. It is mounted on the engine valve cover or intake manifold.
PCV valve tester: Tester that measures the exact amount of airflow through a positive crankcase ventilation system.
peak-and-hold fuel injector: Type of fuel injector that uses a high amount of current to open an injector and a low amount of current (less than one amp) to hold the injector open.
pendulum belt retractor: A retractor that uses the inertia of a small hinged metal weight to engage the seat belt's locking mechanism during vehicle deceleration. When the vehicle brakes or stops quickly, a small pendulum in the retractor is thrown forward, causing the belt-locking mechanism to engage.
pent-roof combustion chamber: Combustion chamber that resembles a hemispherical combustion chamber, but with flat, angled surfaces.
permanent-magnet starter: Starting motor that uses high-strength field magnets instead of field windings to rotate the armature.
petroleum: See *crude oil.*
phosphorous additive: Nonmetal additive used as a cleaning agent in motor oil to carry oil impurities to an oil filter.
photon: A particle of electromagnetic light energy.

Copyright Goodheart-Willcox Co., Inc.

photonic device: Any device that can emit or detect light.
photoresistor: A semiconductor that acts as a resistor in the dark, but changes to a conductor when exposed to light.
phototransistor: An electronic device that conducts current through its emitter-collector junction when excited by light. When light is blocked, the emitter-collector junction changes to an insulator and blocks current.
photovoltaic cell: A photonic device that converts light directly into current. It consists of N-type and P-type semiconductor materials that can absorb light energy in the form of photons and an antireflective layer that helps it absorb more light energy, making it more efficient. It is also called a solar cell.
physical injury: Cuts, broken bones, strained backs, and other ailments that can result from hundreds of different accidents. Safety in the workplace prevents accidents.
pickup screen: Screen that prevents large particles from entering the pickup tube and oil pump.
pickup-sending unit: A variable resistor that extends down into a fuel tank to draw out fuel and operate the fuel gauge.
pickup tool: A tool with a magnet hinged to the end of a telescoping rod. If bolts, nuts, or other small iron parts are dropped out-of-reach, this tool can be used to attract and grab the item.
piezo diesel injection: Type of diesel fuel injection that uses a high-pressure mechanical pump and an electrically operated piezo crystal to force an injector nozzle open.
piezo diesel injector: Diesel injector that uses a crystalline ceramic material instead of an electromagnet to open the injector valve.
piezo fuel injector: Type of fuel injector that uses a crystalline ceramic material, instead of an electromagnet, that converts electrical energy directly into motion to open an injector valve.
piezoelectric crystal: Crystalline ceramic material that produces a small output signal when exposed to physical strain or pressure.
pilot: A steel shaft that is installed in a valve guide to support a grinding stone used for valve seat reconditioning.
pilot bearing: Bearing that fits into the bore at the center of the crankshaft flange, providing the front support for the transmission input shaft.
pilot bushing: Bronze bushing that fits into the bore at the center of the crankshaft flange, providing the front support for the transmission input shaft.
pilot-operated absolute valve: An A/C system control that is used with the expansion valve to control evaporator temperature.
pilot shaft: Metal support shaft inserted through the transmission input bore to hold up clutch plate pieces during disassembly or reassembly.
pin hole diameter: Distance measured across the inside of a piston pin hole.
pin number: Number used to identify the location and purpose (electrical value and internal connection) of each terminal in a computer wiring harness connector.
ping: Mild knock or metallic rattling noise (not as loud as a detonation knock) that can be heard during preignition and engine acceleration.
pinging: See *ping*.
pinion bearing preload: The force applied to a pinion bearing to eliminate excess play and clearance.
pinion gear: A small gear that is either driven by or driving a larger gear.
pinion gear depth: Distance that a pinion gear extends into its carrier to mesh with the ring gear. It can be adjusted with a shim of different thickness added to the pinion gear and bearing assembly.
pinion gear shim: Metal ring commonly used to control pinion gear depth or pinion bearing preload if solid spacers are used.
pinion pilot bearing: Roller bearing at the end of the pinion gear that provides extra support under severe demands.
pinion shaft: Shaft holding the two differential idler (pinion) gears.
pinpoint test: A specific, sometimes complex, test of an individual component. Vehicle service manuals will usually explain these tests and provide other necessary critical information.
pintle response: Amount of time for the pintle to move as the magnetic field in an injector coil builds.
pipe wrench: An adjustable wrench with toothed jaws used to grasp cylindrical objects.
piston: Component that rides up and down in a cylinder to transfer force or build pressure.
piston and servo: Devices that operate clutches and bands in an automatic transmission/transaxle; they are activated by oil pressure from the valve body.
piston boot: Rubber covering that keeps road dirt and water off the caliper piston and the wall of the cylinder.
piston boss: Reinforced area around the piston pin hole that supports the piston pin under severe loads.
piston breakage: Part of a piston is cracked or broken, most commonly the skirt.
piston clearance: Distance between the side of a piston and the cylinder wall.
piston diameter: Distance measured across the sides of a piston. Allow for slight changes in this measurement due to piston taper.
piston displacement: The volume of space in which a piston moves from BDC to TDC. Measurements for piston stroke and cylinder size are needed for calculation.
piston head: The top portion of a piston that is exposed to the heat and pressure of combustion. It is also called the piston crown.
piston head shape: Contour of a piston top chosen to work with the shape of the cylinder head combustion chamber.
piston knock: A loud metallic knocking sound produced when a piston flops back and forth inside its cylinder. It is caused by piston skirt or cylinder wear, excessive piston-to-cylinder clearance, or mechanical damage. It is also called piston slap.
piston pin: Fastening device that slides through a machined hole in a piston to hold the piston onto a connecting rod.
piston pin hole: A machined hole through a piston that accepts a piston pin.
piston pin knock: Double knocking sound from a pin hammering against the rod or piston as the piston changes direction in the cylinder. Excessive clearance between a piston pin and piston pin bore or connecting rod bushing can cause the noise.
piston pin offset: Practice that locates a piston pin hole to one side of a piston centerline, slightly toward the piston's major thrust surface, to quiet its operation.
piston ring: A split ring installed in a groove in the piston. It seals the compression chamber from the crankcase.
piston ring gap: The clearance between the ends of a piston ring when it is installed in a cylinder. It allows for installation and tension against a cylinder wall after cylinder wear.
piston ring groove: Slot machined in a piston to accept a piston ring.
piston ring radial wall thickness: Distance from the face of a piston ring to its inner wall.
piston ring side clearance: Distance between the side of a compression ring and the piston groove.
piston ring width: Distance from the top of a piston ring to the bottom of the ring.
piston seal: Seal in a brake caliper that prevents pressure leakage between the piston and cylinder.
piston skirt: The side of the piston below the last ring. It keeps the piston from tipping in its cylinder.
piston slap: See *piston knock*.
piston stroke: Distance that a piston moves from bottom dead center (BDC) to top dead center (TDC).
piston taper: Slight difference in piston top diameter from the piston bottom when cold. A taper makes a piston almost equal in size at the top and bottom when hot.
piston wear: Decrease in the piston diameter due to friction, commonly measured on the skirt right below the piston pin hole.
piston-to-cylinder clearance: Distance between the edge of a piston and the cylinder wall.
pitman arm: Arm that converts the turning movement of a gearbox sector gear to linear motion and transfers this motion to the steering linkage.
pivot ring: Ring built into a pressure plate assembly, located near the outer rim. The ring holds the diaphragm spring as it flexes during operation.
planar zirconia oxygen sensor: Type of oxygen sensor in which the zirconia element, electrodes, and heater are combined in a flat, laminated strip. This reduces contamination and vibration.
planetary gearset: Gear assembly in which a planet gear, housed inside a planet gear carrier, revolves around a central sun gear and ring gear. It is used in transfer cases, manual transmissions with overdrive units, and automatic transmissions. They

Copyright Goodheart-Willcox Co., Inc.

provide gear reduction, direct drive, and overdrive.

plastic hammer: A light hammer with a soft head that is used where light blows are needed to prevent part breakage or damage.

plateau honing: Honing process that uses extra fine stones to final size cylinder dimensions and final smooth the surface finish. It also produces the desired crosshatch pattern in cylinder walls.

pleated fuel filter: Plastic or coated paper filter resembling an accordion in design. It is the most common fuel filter element found in gasoline fuel systems.

pliers: A handheld tool used to grip, cut, crimp, hold, and bend various parts. Different pliers are designed for different tasks.

plug-in hybrid electric vehicle (PHEV): Gas-electric hybrid vehicle designed with a battery pack that can be recharged in 4–8 hours by plugging into a high-voltage battery charger. This allows for 30–40 miles of electric only driving before the internal combustion engine kicks in to recharge the HV battery.

plunger return spring: Spring that keeps a downward pressure on injection pump plungers and roller tappets. This holds the tappets against the camshaft when the lobes rotate away from the rollers.

plunging joint: A type of constant velocity joint that can shift and slide in its housing to counteract shaft movements.

ply separation: Condition in which tire plies pull apart as a result of overheating due to underinflation, or other causes.

p-metric: Size designation system for tires that uses metric values and international standards.

PN junction: The common edge of the P-type and N-type semiconductors.

pneumatic: Term for tools or equipment that are filled or powered with pressurized air.

PNP transistor: A transistor that has two P-type semiconductors and one N-type semiconductor.

pocket rule: A rule, typically 6" long, that easily fits in a pocket. It is also called a pocket scale.

pole shoe: Placed around the inside of the armature housing. Field windings coil around the pole shoes. When current passes through the winding, it creates a magnetic field between the poles to spin the armature.

poor fuel economy: Condition in which an engine consumes too much fuel compared to engine load and the manufacturer's estimated MPG rating.

pop tester: Manually operated device for checking a diesel injection nozzle spray pattern, opening pressure, and leakage while it is out of the engine.

poppet valve: A valve used to open and close a circular port or hole. It is also termed a mushroom valve.

portable electric drill: A handheld drill that can have a rechargeable battery or a power cord. It can be taken directly to the repair area.

positive battery cable: Cable that is normally red and fastens to the starter solenoid.

positive camber: The tops of the wheels tilt outward when viewed from the front of the vehicle.

positive caster: Tilts the top of the steering knuckle toward the rear of the vehicle.

positive charge: An atom is said to have a positive charge if it holds excess protons.

positive crankcase ventilation (PCV) system: Emission control system that prevents the release of crankcase vapors to the atmosphere by channeling them to the intake manifold.

positive post: Battery post marked in red and with a positive (+) symbol. It is larger than the negative battery post.

potential difference: See *voltage.*

potentiometer: A variable resistor with three external connections that can be used to adjust voltage in a circuit.

power: Rate at which work is done. It is measured in foot-pounds per second or per minute. The metric unit for power is the watt (kilowatt).

power antenna: A radio antenna equipped with a small electric motor for raising and lowering.

power booster: See *stereo amplifier.*

power brake: Brake system that uses a booster and either engine vacuum, electric pump, or hydraulic pressure to assist brake pedal application.

power brush: Brush mounted in a drill and used to remove hard carbon deposits.

power cylinder: A hydraulic cylinder that holds the power piston in a power steering system. It can be a separate part attached to the system or integrated into the steering gearbox.

power distribution diagram: A diagram that shows how battery current feeds to the main components or sections of the vehicle's electrical system.

power door lock: A lock that uses switches to activate solenoids inside a vehicle door to move the latch mechanism.

power hone: A machine shop tool that sizes and finishes the cylinder walls in an engine block.

power mirror: Rear view mirror that uses a tiny electric motor to pivot the mirror. A multi-position switch activates the small motor inside the mirror.

power piston: A hydraulic, double-acting piston housed in the power cylinder of a power steering system. It moves from left to right based on oil pressure to aid in vehicle steering.

power rack-and-pinion steering: Rack-and-pinion steering system that uses hydraulic pump pressure to assist the driver in moving the rack and the front wheels.

power seat: Type of vehicle seat that uses switches, electric motors, and drive assemblies to change the seat position.

power seat module: Computer module that can be programmed to return a vehicle seat to a desired position for different drivers.

power splitter: Device that contains a planetary gearset and is used to control the transfer of power through a hybrid drive train.

power steering fluid reservoir: A separate container that holds an extra supply of power steering fluid. It can also be formed as part of a power steering pump body.

power steering hose: High-pressure, hydraulic, rubber hoses that connect the power steering pump and the integral gearbox or the power cylinder.

power steering oil cooler: A small metal line or radiator located in one of the power steering lines that is used to remove excess heat from the oil.

power steering pressure test: Set of tests that uses a pressure gauge and shutoff valve to measure the pressure and operation of power steering system components.

power steering pump: Engine belt-driven pump that produces the hydraulic pressure for vehicle steering system operation.

power steering system: System that uses hydraulic pressure to assist a driver's efforts when turning the steering wheel. It could also use an electric motor in the rack to provide power assist.

power steering wheel: A steering wheel that uses a computer and various switches, sensors, and motors to automatically tilt and telescope (extend or retract) the steering wheel.

power stroke: The downward movement of the piston, propelled by the expansion of gases, that occurs after the air-fuel charge has been ignited.

power switch: Used in a cruise control system to feed current to the computer to activate and ready the system for operation.

power tilt steering column: Steering column that uses a small electric motor, a control switch, and a gear mechanism to change steering wheel angle or height.

power tool: A tool driven by compressed air, electricity, or pressurized liquid. This type of tool is faster to use and provides greater force than manual tools.

powertrain: Group of components such as the engine, transmission, axles, joints; used to provide driving force to the wheels.

powertrain control module (PCM): Name for a computer that controls the engine, transmission, and emission system of a vehicle.

power trunk release: Consists of a solenoid mounted on the trunk latch, a fuse, a switch, and related wiring. When powered, the solenoid plunger acts on the trunk latch to pop the trunk open.

power window: A window that uses a small direct current motor to move the window glass up and down.

power window motor: Electric motor located inside each door to operate the window regulator (up-down mechanism for the glass).

prechamber cup: Cup that forms an enclosure in diesel engines around the tip of an injector and glow plug known as the precombustion chamber. The cups are force-fitted into precisely machined holes in the cylinder head deck surface.

precombustion chamber: A small chamber at the top of a diesel engine cylinder. Diesel fuel is injected into this chamber and warmed by

Copyright Goodheart-Willcox Co., Inc.

a glow plug and compression. Combustion begins in the precombustion chamber and expands into the combustion chamber. It is also called a diesel prechamber.

preignition: Problem that results when an overheated surface in the combustion chamber ignites the air-fuel mixture, causing it to burn prematurely. It is also called surface ignition.

preliminary visual inspection: An initial examination of a vehicle to find obvious signs of trouble, including loose wires, leaking vacuum hoses, part damage, and other problematic items.

pressed-in valve guide: Separate sleeve made of cast iron, steel, or bronze that are force-fitted into a hole machined in the cylinder head.

pressed-in valve seat: Separate, machined valve seat forced into a recess cut in a cylinder head. It is also called a seat insert.

press-fit piston pin: Piston pin that is force-fitted into a connecting rod but is free to rotate in the piston pin hole. This design prevents the pin from sliding out to rub on the cylinder wall.

pressure blaster: An enclosed cabinet for sandblasting and for cleaning dry parts. It has protective rubber gloves that extend into the cabinet for holding and positioning parts.

pressure bleeding: Process of bleeding a brake system using a pressure bleeder tank, which contains brake fluid under pressure.

pressure cycling switch: Used in place of or in conjunction with a thermostatic switch to maintain the correct evaporator temperature.

pressure differential valve: See *brake warning light switch.*

pressure-fed oiling: Oil is forced, under pressure, through galleries and to moving parts of an engine by a pump.

pressure gauge: Gauge used to check various positive air or fluid pressures, such as fuel pump pressure or engine oil pressure. It measures in pounds per square inch (psi), kilograms per square centimeter (kg/cm^2), or kilopascals (kPa).

pressure line: Air hose that connects the compressor to the air shock absorbers.

pressure plate: In a manual transmission, a spring-loaded disc assembly that pushes and locks the clutch disc against the flywheel. In an automatic transmission, a metal plate in a clutch assembly that acts as a barrier for clutch discs to be pressed against during clutch engagement.

pressure plate cover: Metal housing that bolts to a flywheel and is used to hold together the parts of a pressure plate assembly in a manual transmission.

pressure plate face: Metal ring on one side of a pressure plate in a manual transmission that contacts the clutch disc during gear shifts.

pressure plate release lever: Lever mounted inside a coil spring style pressure plate assembly that moves the pressure plate face away from the clutch disc and flywheel in a manual transmission.

pressure regulator: A spring-loaded valve that limits the maximum hydraulic oil pressure in an automatic transmission. *Also,* a part of a shop's compressed-air system used to set a specific pressure for the system.

pressure relief valve: Spring-loaded bypass valve that operates when pressure reaches a preset point.

pressure tester: Hand-operated air pump used to pressurize the cooling system for leak detection.

pressure testing: Test that pressurizes the coolant and oil passages in a temporarily sealed engine block and submerges the block in a water tank to find cracks or flaws.

primary brake shoe: Term for the front shoe that normally has a slightly shorter lining than the secondary shoe.

primary circuit: The section of an ignition system that consists of all of the components and wires that operate on low voltage from the battery or alternator. Small, conventional wires carry primary currents.

primary oxygen sensor: Sensor, positioned before the catalytic converter and as close to the engine as possible, used to monitor the oxygen in the exhaust gases as it leaves the engine. It is also referred to as the front O_2 sensor.

primary piston: In the dual master cylinder, it is the term for the rear piston assembly.

primary scope pattern: Scope pattern that shows the low-voltage, or primary-voltage, changes in an ignition system.

primary superimposed pattern: Scope pattern that shows the low voltages in the primary system (the ignition module or the condenser, coil primary windings, and points) with all the cylinder waveforms displayed on top of each other.

primary winding: Low-voltage winding in a coil. It is made of heavy wire.

primary wire: Small insulated wire that carries low-voltage to the components, circuits, and ECUs in a vehicle. It is also called body wire.

printed circuit: An electrical circuit that is made by conductive strips printed on a board or panel.

problem symptom: Noticeable performance change to a vehicle system or part, such as abnormal noise, loss of power, rough idle, hesitation, etc.

processing: A computer's comparison of sensor inputs to data and operating ranges in its memory to determine a course of action.

professionalism: A representation of a highly motivated, skilled, and competent individual within a career path or job.

programmable read only memory (PROM): A semiconductor chip that contains instructions that are permanently encoded into the chip. Instructions contain base operating information for how a system's components should operate under various conditions.

prompt: Step-by-step instruction, programmed into a scan tool circuitry or cartridge, that tells how to input vehicle information and run diagnostics.

propellant charge: Expanding gas in an air bag that is usually produced by the burning of sodium azide pellets in the air bag ECM.

propeller shaft: See *drive shaft.*

proportional rack-and-pinion power steering: System that senses vehicle speed and steering load to ensure adequate road feel. It increases wheel effort at higher speeds for more road feel and lowers wheel effort at low speeds to help steer. It is also known as speed-sensitive power steering.

proportioning valve: Valve used to equalize braking action in systems with front disc brakes and rear drum brakes to prevent wheel lockup. It is commonly located in the brake line to the rear drum brakes.

proton: Positively charged component in the nucleus of an atom.

proximity sensor: Device (usually sonar or sound sensor) around the perimeter of a vehicle that measures the distance from the auto body to anything around the vehicle.

Prussian blue: A metal stain often used to spot metal parts during layout. It can be used to check the valve-to-seat contact.

pry bar: Strong steel bars that are used to adjust/move parts during various automotive repairs.

P-type semiconductor: A semiconductor that is doped so that it has excess protons.

puller: Tool used to remove gears, pulleys, seals, and other press-fit parts. Different types and designs of pullers are used for various functions.

pulling brake: A condition where the vehicle will veer to the right or left when the brakes are applied.

pull-pull cable: A manual temperature control that loops cable in its housing so that it always pulls when activated.

pulsating clutch pedal: Problem that occurs when a clutch pedal makes small up and down motions when depressed. This can be caused by vibration from a rotating clutch component, or a warped or misaligned part or clutch housing.

pulse air system: System forcing fresh air into the exhaust ports of an engine by using the pressure pulses in the exhaust system to operate check valves.

pulse width: The speed of a voltage signal change over time. High frequency signals have a short pulse width and low frequency signals have a long pulse width.

punch: Removal and starting tool designed to be struck with a hammer. It is used to remove pins, plugs, and other pressed-in parts from bores as well as provide an indentation to start a drill bit.

purge line: Line connecting the charcoal canister and engine intake manifold.

purge valve: Vacuum- or computer-operated valve that controls the flow of fuel vapor stored in the charcoal canister to the intake manifold.

push rod: Metal tube with specially formed ends that transfers motion between the lifters and rocker arms in cam-in-block engines.

push rod guide plate: Machined plate bolted to a cylinder head to hold a push rod in alignment with the rocker arm.

Copyright Goodheart-Willcox Co., Inc.

push rod service: Maintenance service that involves checking for push rod tip wear and straightness.
push-pull cable: A manual temperature control that uses a stiff steel cable that slides back and forth in its housing.

Q

quick charger: See *fast charger.*
quick-disconnect coupling: Type of coupling used on air hoses in a compressed-air system. The outer sleeve of the coupling can be pulled back to attach or detach the tips of power tools or other equipment.

R

R-12: See *refrigerant-12.*
R-134a: Refrigerant used in the air conditioning systems of most vehicles manufactured after 1992. It replaced R-12 due to environmental concerns.
race: Term for engine speed (rpm) increasing drastically without a corresponding increase in vehicle speed.
rack: A flat toothed steel bar inside a rack-and-pinion steering system that is moved left or right by the pinion gear. *Also,* a part of an alignment machine that is comprised of the ramps, turning radius gauges, and one of several types of equipment for measuring alignment angles.
rack-and-pinion steering gear: A steering gear that utilizes a pinion gear on the end of the steering shaft. The pinion gear engages a long, toothed rack, which is connected to the steering arms via tie-rods.
rack-and-pinion steering system: A simple steering system that uses a pinion gear directly meshing with a steering rack bar to convert the rotation of the steering wheel to straight line movement at the wheels.
radar sensor: Sensor that transmits electromagnetic energy waves from the front of a vehicle. In a collision avoidance system, when the waves hit an object and return to the sensor, the computer interprets the information.
radial ply tire: Tire construction method that has plies running straight across from bead to bead, with stabilizer belts directly beneath the tread.
radial runout: A measure of out-of-roundness, which causes uneven rotation. It is measured at right angles to the centerline of an object.
radiation: A method of heat transfer that is commonly carried out by infrared waves (rays from the sun, for example).
radiator: An arrangement of tubes and cooling fins that serves as a heat exchanger on a vehicle.
radiator cap: Cap that seals and pressurizes the cooling system of a vehicle.
radiator cap pressure test: Test that measures the cap opening pressure and checks the condition of the sealing washer.
radiator cap pressure valve: Spring-loaded valve that seals the radiator filler neck, but will open to release pressure if the engine overheats and cooling pressure exceeds the cap rating.
radiator cap vacuum valve: Small valve that opens to allow flow back into a radiator when the coolant temperature drops after engine operation.
radiator core: Fragile center section of a radiator made up of tubes and cooling fins soldered or bonded together. Coolant heat is transferred into the air flowing through these coolant filled tubes running through the core.
radiator filler neck: Opening for adding coolant that holds a removable radiator pressure cap to prevent coolant boiling when above 212°F (100°C).
radiator hose: Flexible tube that carries coolant between the engine and radiator.
radiator petcock: Fitting on the bottom of a radiator tank for draining coolant.
radiator shroud: Plastic or metal enclosure that keeps air from circulating between the back of the radiator and the front of the fan; typically attached to the rear of the radiator and surrounds the fan.
radiator tank: Metal or plastic end that fits over the core tube ends to provide storage for coolant and fittings for hoses.
radio: Term referring to the transmission of information through electromagnetic waves with frequencies below visible light.
radio frequency: Specific alignment of electromagnetic waves that is transmitted by different radio stations to send their information.
radio noise: Undesired interference or static (popping, clicking, or crackling) obstructing the normal sound of the radio station.
radio station: Broadcasting company that sends out an electromagnetic signal from a large broadcasting tower.
radio suppression wire: See *resistance wire.*
radio system: In a vehicle, it consists basically of an antenna, radio (receiver-amplifier), power supply circuits from an ECM, and speakers.
rain-sensing wiper system: Windshield wiper system that automatically turns the windshield wipers on when water is detected on the windshield. The system uses a moisture sensor with an infrared system to detect water on the outer surface of the windshield.
random access memory (RAM): A portion of computer memory that serves as temporary storage for data. This data is lost if power to the computer is lost. It is used to store sensor information and diagnostic trouble codes.
random cylinder misfire code: Diagnostic trouble code indicating that a problem is occurring in all cylinders.
raster pattern: Oscilloscope reading in which voltage waveforms are placed one above the other on the screen. It is also called a stacked pattern.
ratchet differential: Type of automatic locking differential that uses a dog clutch to lock the axle for 100% torque applied to both driving wheels or unlock the axle to allow different wheel speeds when cornering. It is commonly called a Detroit locker.
read only memory (ROM): A type of computer memory that stores permanent data that cannot be removed from memory. It contains the general information to operate a computer.
reading tires: Inspecting tire tread wear and diagnosing the cause for any abnormal wear.
reapply mode: An ABS operation mode whereby the ABS applies hydraulic pressure to one or more of the wheel brake assemblies.
rear axle bearing: Ball or roller bearing that fits between the rear axles and the inside of the rear axle housing to reduce friction.
rear axle ratio: The relationship between the numbers of teeth on the pinion gear and ring gear. Ratio affects acceleration, pulling power, and fuel economy. It is also called the differential ratio.
rear axle seal: Seal that fits into an axle housing. The seal lips contact the axle or axle collar to prevent lubricant leakage.
rear drive axle: Shaft that transfers power from the rear differential assembly to the vehicle's rear wheels. The axles may be straight shafts, or they may be equipped with cross-and-roller U-joints or CV joints.
rear drive axle assembly: Differential, axles, and other components transferring power from driveline to rear wheels.
rear end: Term for a rear drive axle assembly.
rear main oil seal: Seal that fits around the rear of the crankshaft to prevent oil leakage.
rear O_2 sensor: See *secondary oxygen sensor.*
rear seat air bag: Air bag that fits into the rear cushion of the front seats. It inflates to protect the passengers in the rear seat from injury during a frontal collision.
rear universal joint: Flexible joint that connects a drive shaft to the rear yoke.
rear wheel bearing: Ball- or roller-type bearing that reduces friction between the axle and axle housing.
rear window defogger: System that uses a switch, a relay, an indicating light, and a window heating grid that heats up to defog or deice the vehicle's window when activated. It is also called a rear window defroster.
rear window defroster: See *rear window defogger.*
rear yoke: Driveline component that holds a rear universal joint and transfers torque to gears in the rear axle assembly and differential.
rear-wheel drive: Configuration with the engine in the front of a vehicle and the drive wheels in the rear. Due to vehicle weight being more evenly dispersed, this drive train configuration offers more precise steering than front-engine, front-wheel drive vehicles.
rebound: Term for the extension of a suspension system spring.
receiver-drier: Removes moisture from the cooling system and stores extra refrigerant.
reciprocal: Of a number, it equals 1 divided by that number.

Copyright Goodheart-Willcox Co., Inc.

reciprocal method: A method that can be used to calculate resistance in all parallel circuits. In this method, the reciprocal of the total resistance equals the sum of the reciprocals of all of the branch resistances.

reciprocating electric fuel pump: Similar to a mechanical fuel pump with its back-and-forth pumping motion but uses a solenoid instead of a rocker arm to produce this motion.

reciprocating weight: The weight of engine parts, including bearings, rings, and oil, during operation.

recirculating-ball gearbox: Worm-style steering gearbox that has small steel balls that circulate between rotating gear members.

rectification: The process of converting alternating current to direct current.

rectifier diode: Diodes, commonly six, that provide full-wave rectification when converting stator current to direct current inside the alternator.

reduction starter: Starter that uses an extra set of gears to improve gear reduction that increases the rotating force applied to the engine flywheel.

reed valve: A flexible metal flap that exposes ported holes to allow the entrance and exit of gases from the crankcase in a two-stroke engine. *Also*, a thin piece of metal in an A/C compressor that bends to open and close an opening. They are normally used as check valves to produce flow through the compressor and system.

reference voltage (Vref): A known voltage (usually 1–5V) fed to passive sensors by a computer. Changes in sensor resistance can then be read by the computer as a change in current.

reference voltage test: Test that uses a multimeter to measure the ECM reference voltages being sent out to resistive sensors.

refinery: Complex where newly extracted crude oil is converted into more useful substances, such as motor oil, gasoline, and diesel fuel. It is also referred to as surface ignition.

refractometer: Handheld type of coolant strength measuring device in which a drop of coolant is placed on a scaled measuring window and then examined through an eyepiece.

refrigerant: A substance with a very low boiling point that is circulated through a refrigeration, or air conditioning, system.

refrigerent-12 (R-12): Refrigerant used in older air conditioning systems. It has been replaced by R-134a. It is also called R-12 or Freon.

refrigerant hose: Hose that carries refrigerant to each air conditioning system component and back to the compressor.

refrigerant oil: Lubricant used in the compressor of an air conditioning system.

refrigerant system: Uses a confined gas to provide cool, dehumidified (dried) airflow into the passenger compartment.

regenerative braking: Braking system in a hybrid vehicle that uses the energy from slowing the rotational force of the vehicle's drive axles to spin the motor generator, causing the motor generator to produce electrical energy to recharge the battery.

relay: A magnetically operated switch that enables low current in one circuit to control (close or open) a greater current flow in a second circuit.

relay rod: See *center link.*

relay tester: Test device for relay operation. Special relay testers can work quickly by plugging into a relay outlet and testing it automatically.

relearn procedure: Process and time period after vehicle service during which the computer system adjusts to new components and programming information.

release arm: See *clutch fork.*

release bearing: Bearing that applies force to the release levers or fingers of a pressure plate to disengage the clutch disc from the flywheel. It is also called a throw-out bearing.

release rod: Rod in a clutch linkage mechanism connected to the bellcrank to transfer bellcrank movement to the clutch fork.

relief valve: Valve that limits the maximum output pressure of a pump.

reminder system: Vehicle warning system that makes an audible signal (buzz, chime, or audible warning) if seat belts are not fastened when the engine is started, keys are left in the ignition with the engine off, or headlamps are left on with the engine off and a door open.

remote ground: A method of grounding a circuit in that an extra wire is connected from the circuit to ground.

removable carrier: Separate housing for the differential assembly that can be unbolted and removed from the rest of the rear axle housing after the drive axles are removed.

repair area: Any section within an auto repair shop where repair operations are performed.

repair information section: Part of a vehicle inspection report which provides a vehicle owner with instructions for having the vehicle repaired if it fails an emission test.

reserve capacity rating: Time needed to lower 12-volt battery terminal voltage below 10.2 volts at a discharge rate of 25 amps. The rating assumes that the test starts with a fully charged battery at 80°F (27°C).

residual pressure valve: Maintain residual fluid pressure of approximately 10 psi (69 kPa) to help keep contaminants out of a hydraulic brake system.

resistance: The measure of opposition to electrical flow in a circuit.

resistance key: Theft deterrent ignition key with a small electrical resistor mounted on the side. The metal teeth and resistance of the key must match the value programmed into the control module for the vehicle to start normally.

resistance wire: Wire that contains internal resistance (carbon-impregnated strands of rayon braid) to prevent radio noise. The wire has about 10,000 ohms of resistance per foot. It is also known as radio suppression wire.

resistor: A device placed in a circuit to lower voltage and current flow.

resistor spark plug: Spark plug that has an internal resistor built into the center electrode. The resistor has a resistance of about 10,000 ohms. This resistance is designed to reduce induced static in radios and to increase spark plug life by reducing tip erosion.

respirator: A device worn when working with harmful airborne materials that filters dangerous particles from the air a technician breathes.

résumé: A mandatory job search document that summarizes a job applicant's work history, education, qualifications, and skills required for an employment position.

resume switch: Switch in a vehicle cruise control system that allows a driver to reset the same cruising speed when desired.

retainer: The individualized bracket and fasteners that hold a battery in its tray.

retainer plate type axle: Type of axle that uses an axle retainer plate bolted to the axle housing to hold the axle in place. This design is often used with a removable rear axle carrier.

retaining collar: Plastic strap or metal spring clamp in a constant velocity joint assembly. The retainer tightens on the boot end to secure it on the axle shaft and to the universal joint housing. It is also called a strap.

retarded ignition timing: Occurs when the ignition spark happens after the manufacturer's specified position of the piston during the compression stroke. This causes the engine to have poor fuel economy and lack power, especially during acceleration.

retracting spring: Spring that pulls the brake shoes away from the brake drums when the brake pedal is released. This, in turn, pushes the wheel cylinder pistons inward.

retread: Name for used tire that has undergone a process involving heat and pressure to apply a new tread to the tire body. It is rarely done on a passenger vehicle tire.

returnless fuel injection system: Type of fuel system that does not have fuel return lines to the tank. The design helps reduce evaporative emissions by minimizing fuel vaporization.

reverse bias: Arrangement in which a diode acts as an insulator.

reverse bias voltage: A rating of the maximum voltage a diode can block without being damaged.

reverse idler gear assembly: Separate machined gear assembly on a shaft located close to the countershaft. It changes gear rotation so the vehicle moves in reverse.

reverse idler shaft: A short shaft that supports the reverse idler gear assembly.

reverse-biased diode: Diode that acts like an insulator, not allowing current to pass through the diode when voltage is connected in a certain way.

reverse-flow cooling: Type of engine cooling in which cool coolant enters the cylinder head and hot coolant exits the block to return to the radiator.

rheostat: A variable resistor with two electrical connections (terminals). One terminal is wired to one end of the resistance unit.

Copyright Goodheart-Willcox Co., Inc.

The other terminal is connected to a sliding contact. Turning the control knob moves the contact and alters the resistance value.

rich air-fuel mixture: Fuel mixture that contains a large amount of fuel compared to air.

rich trouble code: Diagnostic code set if an O_2 sensor detects too much fuel is being injected into the cylinder for engine speed and load.

right-to-know law: Mandates that essential information and stipulations for safely working with hazardous materials be available to those handling them.

rim: Outer lip of a wheel that contacts the tire bead.

ring and pinion backlash: Clearance between the meshing teeth of the ring and pinion gears, needed for lubrication and heat expansion during operation.

ring and pinion contact pattern: Markings on a ring and pinion gear after spinning them together with an applied test substance. The pattern can be used to double-check or correct the gear adjustment.

ring back clearance: Distance determined from the difference between a piston ring radial wall thickness and ring groove depth.

ring configuration: Computer network configuration in which each computer is wired in series, or in a loop.

ring expander: A special tool for spreading and installing piston rings. *Also*, a ring placed behind a one-piece oil ring that increases ring tension against the cylinder wall.

ring expander-spacer: Ring installed between the two steel oil rings in a two-piece oil ring to hold the rings apart and push them outward against the cylinder wall.

ring filing: Process using a special, thin grinding wheel to remove metal from the ends of a piston ring.

ring gear: Large gear in differential that is driven by the pinion gear and, in turn, drives the spider gears.

ring gear runout: Measured amount of side-to-side movement when a ring gear is rotated.

ring groove depth: Distance measured from the tip of a ring land to the back of the ring groove. When installing a new ring, depth should be checked to make sure the new ring will fit below the surface of the piston.

ring groove width: Distance measured from the top to the bottom of the ring groove.

ring land: Area between and above piston ring grooves. It separates and supports a piston ring as it slides on the cylinder.

ring seating: Initial piston ring wear that allows the ring to perfectly match the surface of a cylinder.

ring side clearance: Distance determined from the difference between a piston ring width and ring groove width.

rising edge: Oscilloscope reading where the square wave goes from zero to high voltage. It is also called the leading edge.

road crown: The normal slope toward the outer edge of the road surface.

road crown pull: Steering wheel pull caused by hump in center of road.

road damage: See *tire impact damage.*

road feel: The feeling imparted to the steering wheel by the wheels of the vehicle in motion. This feeling is important in sensing and predetermining steering response.

rocker arm: Pivoted lever that transmits motion through its oscillation used in many parts of an internal combustion engine.

rocker assembly service: Maintenance service involving the cleaning, inspection, and measurement of rocker arms, rocker arm shafts, and related components.

roll-around cart: Wheeled cart with two deep trays that can be easily maneuvered around a shop. It is helpful when moving heavy tools or for eliminating multiple trips to a toolbox.

roller lifter: A hydraulic or mechanical valve lifter that has a roller bearing, which rides on the cam lobe to reduce friction.

roller vane electric fuel pump: A positive-displacement pump normally located in a main fuel line that uses small rollers and an offset-mounted rotor disc to produce fuel pressure.

rolling resistance: Measurement of the amount of friction produced as a tire rolls over a road surface. A high resistance can lead to aggressive and abnormal tire and tread wear.

rollover valve: Valve in the fuel tank or delivery lines that prevents the escape of raw fuel in the event of a vehicle rollover.

root cause of failure: The actual cause of a problem or failure.

rosin-core solder: A type of solder designed for electrical repairs that contains flux (lead-free cleaning agent) inside the solder.

rotary brush: A stiff brush attachment used with an air tool for cleaning parts.

rotary control valve: Valve operated by a torsion shaft connected to the pinion gear in a power rack-and-pinion steering system to route oil to the power cylinder.

rotary engine: An internal combustion engine that uses one or more spinning triangular rotors instead of pistons to accomplish the intake, compression, power, and exhaust cycles. It is also referred to as a Wankel engine.

rotary file: Grooved metal attachment used in a drill or grinder for removing metal burrs and nicks.

rotary fuel pump: Term for a fuel pump that uses a circular, or spinning, motion to produce pressure. Examples include the impeller type, the roller vane type, and the sliding vane type.

rotary oil pump: Type of oil pump that uses a set of star-shaped rotors in a housing to pressurize the motor oil.

rotary valve: A spinning disc-shaped valve that exposes ported holes to allow the entrance and exit of gases from the crankcase in a two-stroke engine. *Also*, a power rack-and-pinion steering control valve composed of a spool valve inside a valve body.

rotor: See *brake disc.*

rough idle: Condition in which an engine seems to vibrate on its mounts at very low rpms.

rpm at misfire: Readout showing engine rpm when the computer detected a cylinder misfire.

rubber boot: Fits over the master cylinder housing and the brake pedal push rod to prevent dust, dirt, and moisture from entering the back of the master cylinder.

rubber bumper: Jounce and rebound bumper that stops metal-to-metal contact during extreme suspension compression and extension.

rubber dust boot: Clamp-secured flexible rubber housing that fits over the inner ball sockets of a rack-and-pinion tie-rod assembly to keep out dirt and water, as well as to hold in lubricating grease.

rubber isolator: Rubber part of an upper strut damper unit that prevents suspension noise from transmitting into the body structure of a vehicle.

rubber mallet: Type of hammer with a head made of solid rubber. It will rebound, or bounce, when used to strike another solid object.

run-flat tire: Tire designed with a stiff sidewall to allow it to run while deflated.

running engine compression test: See *dynamic engine compression test.*

run-on: See *dieseling.*

rust penetrant: A chemical that is sprayed on rusted parts (often rusted fasteners) that dissolves rust or corrosion.

Rzeppa CV joint: A type of constant velocity joint that uses a star-shaped ball-and-cage assembly to provide joint motion. It is used in front-wheel-drive swing axle assemblies.

S

safety data sheets: Documents that list the detailed chemical composition, handling procedures, and precautionary information for products that can present a health or safety hazard on the job site. Manufacturers of such products must provide this information with their products.

safety rim: A wheel designed with two safety ridges to prevent the tire from dropping into the center of the wheel in the event of a blowout.

safety system: Systems that provide protection for vehicle passengers, including seat belts, air bags, and security systems.

safety washer: Flat washer that keeps the outer wheel bearing from rubbing on and turning the spindle adjusting nut on a hub and wheel bearing assembly.

safing sensor: A backup sensor to ensure no accidental air bag deployment by confirming that a vehicle is involved in a collision. It is also called an arming sensor.

satellite radio: Type of radio system that operates off a radio transmitter orbiting in outer space at an altitude of about 22,000 miles (35,000 km) above Earth's surface. The satellite broadcasts use an FCC-allocated broadcast frequency in the S-band (2.3 GHz).

Copyright Goodheart-Willcox Co., Inc.

saturated ignition coil: Term for an ignition coil with a fully formed magnetic field.
scan tool: Electronic tool, usually handheld, that is used to read and interpret diagnostic codes and engine sensor information.
scan tool datastream value: Electrical values measured and displayed in real time with a vehicle running and/or being driven.
scavenge pump: Secondary oil pump in a dry sump lubrication system that pulls oil out of an oil pan and feeds it back into a separate oil reservoir.
schematics: Straightforward graphic representations of an electrical, vacuum, or pressure circuit.
Schrader valve: Type of pneumatic valve that has a valve core consisting of a spring-assisted poppet valve threaded into its valve stem.
scope: See *oscilloscope*.
scope screen: Oscilloscope screen that can give instructions, display voltages as a trace, or give other values as digital displays.
scope sweep rate: Frequency or time division shown on a scope screen during each test.
scope test: Test that analyzes a voltage waveform.
scope time: Displayed on a scope screen along the horizontal axis in degrees, milliseconds, or duty cycle.
scope voltage: Displayed on a scope screen along the vertical axis, or scale.
scratch awl: A tool that resembles a screwdriver, but has a sharp, pointed tip. It is used for marking sheet metal and other parts.
screwdriver: Handheld tool used to remove or install screws. The shape of the tip of a screwdriver determines on what screw it should be used.
screw extractor: Tool used to remove broken screws or other broken fasteners that have broken flush with or below a part surface.
scuff pad: Pad mounted in a drill or similar tool that can cut through and lift off gasket material and silicone, yet is too soft to easily damage metal surfaces.
seal: A formed device made of plastic, rope, neoprene, or Viton. It is used to prevent oil leakage around a moving part, such as a shaft.
sealed-beam headlamp: Headlamp that has its filament(s) enclosed in a vacuum-sealed glass housing.
sealer: Sticky substance applied to parts or a gasket before installation to improve the sealing ability of the gasket, take the place of the gasket, hold the gasket in place during reassembly, or improve the sealing ability of dynamic seals and hose connections.
sealing ring: Piston-type ring placed around the turbo shaft at each end of the turbo housing to prevent oil leakage.
seat belt: Strong nylon straps that hold people in their seat during a collision.
seat belt anchor: Provides a means of bolting the seat belt to the car's body and frame structure.
seat belt buckle: Part of the seat belt that engages and disengages the belt around the occupant's body.
seat belt reminder system: System that activates a dash light and generates an audible tone to warn the vehicle's occupants to buckle their seat belts.
seat cover: Cover placed over a seat to protect it from dirt, oil, and grease during a repair.
seat cushion sensor: Sensor that detects the weight of a person sitting in the passenger seat.
seat narrowing: Process of grinding a valve seat in or out so it correctly contacts a valve face.
seat stone: A grinding stone mounted on a threaded drive attachment used to cut a fresh surface on the face of a valve seat.
seat width: The area of the valve seat that is actually in contact with the valve face.
secondary brake shoe: Term for the rear brake shoe that has the largest lining surface area.
secondary circuit: In an ignition system, all components operating on coil (high) voltage. It carries high voltage from coil to spark plugs.
secondary nonresistance wire: A wire that has a metal conductor with no extra resistance. This type of wire is used only in high-performance applications, such as off-road racing, because it causes static in nearby radios.
secondary operating voltage: Ignition system voltage that ranges from 4,000–100,000 volts, depending on the system design.
secondary oxygen sensor: Sensor, positioned after a primary oxygen sensor in an exhaust system, that primarily monitors a catalytic converter for proper operation. It is also called a rear O_2 sensor.
secondary piston: In a dual brake master cylinder system, it is the term for the front piston.
secondary resistance wire: A wire that has a constrained amount of resistance designed directly into the metal conductor. It is designed to help prevent radio interference or static from the high voltage pulses going to the spark plugs. It is also called carbon-core wire.
secondary scope pattern: Scope pattern that shows the high voltages needed to fire the spark plugs.
secondary superimposed pattern: Scope pattern that shows the high voltages produced by the ignition coils with all the cylinder waveforms displayed on top of each other.
secondary winding: The high-voltage winding in an ignition coil. It is made of several thousand turns of very fine wire.
secondary wire: Wire with extra thick insulation that carries high-voltage electricity from the ignition coil to the spark plug.
secondary wire insulation test: Test used to check for secondary wire leakage or arcing through its insulation to ground or another wire.
secondary wire resistance test: Test that checks the condition of a spark plug or coil wire conductor. This test is used to check for a bad wire when an oscilloscope is not available.
sector shaft: Output shaft/gear in a steering gearbox that transfers motion to the steering linkage.
security system: System of motion sensors and switches that communicate with signals to an electronic control module. If the vehicle is tampered with, theft deterring features are activated.
select-fit: Term for engine parts chosen and installed in a certain position to improve the fit or clearance between parts.
selective catalytic reduction (SCR): An emission control system used on diesel engines that injects diesel exhaust fluid into the vehicle's exhaust stream ahead of a catalytic converter. The converter breaks down toxic NO_X emissions into harmless water and nitrogen.
self-energizing action: Movement when brake shoes are forced against the rotating drum and are pulled away from their pivot point by friction. This draws the shoes tighter against the drum.
self-leveling shock absorber: A shock absorber designed with a hydraulic lock action that holds the shock rod at the same length for normal vehicle curb height under various conditions.
self-sealing tire: A tire with a sealing compound applied to its liner to stop air leakage in case of puncture.
self-stripping connector: Type of connector useful for connecting to an existing wire in a harness because it cuts through a wire's insulation and locks onto the conductor.
semi-automatic transmission: Type of transmission that often uses paddle shift buttons on the steering wheel instead of a console shift lever. Electric actuators switch gear locations semi-automatically based on signals sent to a computer control system from the paddle shifters.
semi-centrifugal pressure plate: Type of pressure plate that reduces slippage at high engine speeds. It uses weighted release levers applying centrifugal force to increase clamping pressure on a clutch disc. Weaker coil springs also allow clutch engagement at low engine speeds.
semiconductor: A substance, such as silicon, that acts as a conductor or insulator, depending on its operating condition and application.
semifloating axle: A type of axle used in most rear-wheel drive vehicles. The outer end of the axle turns the wheels and supports the weight of the vehicle. The splined inner end floats in the differential gear.
semi-independent suspension: A suspension system that uses a flexible axle to allow each wheel to move up and down with minimal influence to the other wheel on that axle.
sending unit: Variable resistor used in dash gauges to control current flow to gauges.
sensor link: A linkage rod that connects the height sensor to the suspension in an electronic height control system.
sensor rotor: A toothed ring that rotates with the wheel hub. As each tooth passes the sensor, it induces an ac signal based on wheel and tire speed. It is also called a trigger wheel.
sensor socket: Specialty socket with a shape and cutout designed to fit over specific vehicle sensors.

Copyright Goodheart-Willcox Co., Inc.

sensor system: Group of devices measuring pressure, temperature, engine speed, and exhaust cleanliness for an engine control module (ECM).
separator: Permeable membrane that fits between battery plates to prevent shorting. It must be resistant to acid and oxidation.
sequential turbocharger system: System designed to reduce turbo lag that uses two electronically controlled turbochargers that operate as needed. It is also called a twin turbocharger system.
serial communication: Means of computer network communication that uses only one wire to exchange digital data. In this setup, data is transferred one bit at a time.
series circuit: An electrical circuit with only one path for current flow.
series hybrid: A gas-electric hybrid vehicle that has a separate generator and traction motor. It does not use a motor-generator. In a series hybrid configuration, the traction motor is the only method used to apply torque to the vehicle's drive train.
series-parallel circuit: A circuit consisting of at least one series circuit and one parallel circuit. It is also known as a combination circuit.
series/parallel hybrid: Gas-electric hybrid vehicle that combines the advantages of the parallel hybrid with those of the series hybrid. The internal combustion engine can power the vehicle, disconnect to let the electric motor propel, or energize a generator to recharge the battery.
service dispatcher: Individual in charge of tracking shop repairs and organizing/assigning technicians to perform each auto repair.
service information: Printed or electronic instructional material that details how to diagnose and repair a vehicle. It may consist of step-by-step procedures, specifications, diagrams, exploded part illustrations, troubleshooting charts, descriptions of common problems for specific vehicle makes and models, and other useful information. It is also referred to as a shop manual.
service manager: Management position responsible for the complete service and repair operation of a large repair facility. The efforts of the shop supervisor, parts specialist, service writer, service dispatcher, and other shop personnel are coordinated by the manager.
service station: An automotive repair location where much of the work is quick service repairs that only take an hour or two.
service writer: Individual who completes repair orders, describing vehicle problem(s), for each vehicle entering a shop.
servo: Piston device that operates a band in an automatic transmission. *Also*, a small dc motor that can turn or move parts.
servo action: With most drum brake designs, shoe energization is supplemented by servo action. Servo action results when the primary (front) shoe helps apply the secondary (rear) shoe.
servo motor: A small dc motor actuator that can produce a rapid spinning motor when energized by a relay or main computer.
servo piston: Plunger part of a servo that moves within a machined cylinder in a transmission case.
servo seal: Seal that fits around a servo piston and cylinder to prevent oil leakage.
set screw: Headless screw most often used to lock a part onto a shaft.
setback: A condition in which one front wheel is set farther back from the front of the vehicle than the other front wheel.
shackle: A bracket for connecting a leaf spring to a vehicle frame that allows length changes in the spring during suspension movement.
sharp valve margin: Condition in which a valve clearance is too small.
sheet metal screw: Screw with tapering threads that are very widely spaced. This type of screw, also called a tapping screw, is used on plastic and sheet metal parts.
shielded twisted-pair conductor: A twisted-pair conductor encased in a metal shield for greater electromagnetic interference reduction.
shielded twisted-pair wire: Wire that consists of multiple insulated conductors wrapped around each other and has a sheath of metal around the conductors to avoid radio interference.
shielded wire: Wire with a flexible metal tube around the conductor to block interference.
shift fork: Pronged device in a manual transmission that straddles and moves the synchronizers and gears back and forth on their shafts for gear engagement.
shift linkage: Mechanical rods, cables, or hydraulic circuits in a manual transmission that connect a shift lever to the shift forks.
shift schedule: A programmed table of perimeters stored in a transmission control module that is used to calculate shift points in an electronically controlled automatic transmission.
shift valve: Valve that uses controlled oil pressure from specific valves to determine the correct gear needed for different engine loads. It is also called a balanced valve.
shock absorber: A piston operating in an oil- or gas-filled cylinder that dampens and controls spring oscillation in suspension systems.
shock absorber bounce test: Simple test to determine shock absorber strength. One corner of a vehicle body is pushed down and then released. The number of times the vehicle body rebounds before stopping is counted—more than three can indicate a problem.
shock absorber compression: The downward movement of the piston and upward flow of oil within the shock cylinder that occurs when the vehicle's tire is forced upward upon hitting a bump.
shock absorber extension: The upward movement of the piston and downward flow of oil within the shock cylinder that occurs as the control arm returns down after a compression.
shock actuator: Solenoid-operated valve that controls fluid flow inside shock absorbers in an electronic shock absorber system.
shop equipment: General term for large tools, such as floor jacks, parts cleaning tanks, steam cleaners, and battery chargers that are used in an automotive shop.
shop stall: A small, designated work area where a vehicle can be parked for repairs.
shop supervisor: Management position that directs technicians and ensures that shop work is correctly performed and in a timely manner.
short circuit: An accidental grounding of an electrical circuit or electrical device, causing a tremendous amount of current through the circuit or device.
shorted diode: A diode that has a low (almost zero) resistance in both directions.
short-term fuel trim: Term for a temporary adjustment of injector pulse width to correct fuel mixture.
shoulder belt: Part of the seat belt that extends across a person's shoulder and chest.
shroud: A plastic or metal enclosure around a fan to guide and facilitate airflow.
side curtain air bag: Air bag designed to drop down like a "curtain" over the side window glass.
side terminal: Female-threaded electrical connection located on the side of a battery. It connects with a special bolt on the battery cable end.
side-impact air bag: Small air bag in the door panels or the outside edge of each front seat that deploys when the vehicle is hit from the side. They generally do not deploy during a frontal impact.
side-impact beam: High-strength steel or carbon fiber beam mounted in the vehicle doors to help prevent intrusion into the passenger compartment.
sidewall: The portion of a tire between the bead and tread.
sight glass: Located in the top of the receiver-drier to show the amount of refrigerant in the system.
signal amplitude: Level of voltage present in a wave. High-amplitude signals have more voltage than low-amplitude signals.
silicone lubricant: A lubricant that comes in a spray can and is used on rubber door weather stripping and windows.
sine wave: The curve that represents alternating current in a basic circuit.
single cylinder misfire code: Diagnostic trouble code that indicates there is a problem in one engine cylinder.
single exhaust system: An exhaust system that has only one pipe leading from the exhaust manifold to the catalytic converter, muffler, and out to the tailpipe.
single overhead cam (SOHC) engine: An engine equipped with one camshaft, that controls both the intake and exhaust valves, in the top of each cylinder head.
single-stage EGR valve: Type of electronic EGR valve that uses only one solenoid and valve to open its exhaust passages.
single-viscosity oil: Rated and designed for a limited range of operating temperatures.
single-wire conductor: Type of conductor with one insulated wire that carries data signals between computers.

Copyright Goodheart-Willcox Co., Inc.

skidpad: Flat, circular driving course used for different vehicle handling tests.
skirt length: Distance from the bottom of a piston skirt to the centerline of a piston pin hole.
slave cylinder: Operating piston assembly inside a cylinder for hydraulic clutch linkage. It is actuated by the hydraulic pressure developed in the master cylinder.
sledgehammer: Type of heavy hammer with an extra large head that produces powerful blows.
sleeve protrusion: Distance that a cylinder sleeve sticks above the block deck. Sleeve protrusion helps seal combustion pressure at the head gasket. It is also called liner protrusion.
sleeving: Process of installing new metal inserts that fit and line the inside of an engine cylinder to protect the block from piston wear.
sliding caliper: The sliding caliper disc brake is a one-piston caliper that is mounted in slots machined in the caliper adapter. The caliper is free to slide sideways in the slots or grooves as the linings wear.
sliding vane electric fuel pump: A positive-displacement pump normally located in a main fuel line. It uses small square vanes and an offset-mounted rotor disc to produce fuel pressure.
slip joint: See *slip yoke*.
slip yoke: Driveline component that connects a drive shaft to a transmission output shaft and allows back-and-forth drive shaft movement in response to road conditions. It is also called a slip joint.
slow charger: Machine that feeds a small amount of current into the battery to recharge at a slow pace—about 12 hours at 10 amps. It is considered ideal over fast charging because the atomic charges are better forced back onto the battery plates and electrolyte. It is also called a trickle charger.
slow-cranking condition: Engine problem in which the crankshaft rotates slower than normal upon ignition and struggles to start the engine.
sluggish engine: See *lack of engine power*.
smart key system: Feature of some late-model vehicles allowing a driver to lock or unlock doors, open the trunk, or start the vehicle based on the proximity of the key fob to the vehicle.
smart restraint system: Restraint system that uses conventional impact sensor inputs, as well as data from the seat sensors, side door impact sensors, yaw sensors, wheel speed sensors, seat belt sensors, and even collision-predicting sensors.
smog: Generalized term used to describe air pollution caused by chemical fumes and smoke.
snap ring: A semi-flexible metal ring fastener with a opening that allows it to be popped into place. It holds parts within a component, allowing for rotational movement without lateral movement.
snapshot: A scan tool method of recording engine operating conditions at the exact moment that a malfunction occurs.
socket: A small cylinder-shaped, box-end tool in various standard/metric sizes. A socket attaches to a socket handle for removing or installing bolts and nuts.
socket handle: Handle that fits into the square opening in the top of a socket, extension, or universal joint to provide leverage when tightening or loosening fasteners.
soft failure: Computer system failure, also called intermittent failure, that only occurs under certain conditions. It stores in the memory for 30–50 keystarts or warm-ups.
soft ring coating: Porous metal coating on a piston ring. It is used to help the ring wear in quickly and form a good seal in slightly worn engine cylinders.
solar cell: A large solar panel that converts sunlight into electricity.
solar vehicle: A vehicle that uses solar panels to generate electricity for propulsion. Solar panels convert sunlight directly into electric current. The current powers an electric motor, which powers the vehicle.
solar ventilation ECM: A small ECM that monitors and controls the operation of the solar ventilation system.
solar ventilation switch: Allows the solar ventilation system to be manually turned on and off.
solar ventilation system: Uses energy from sunlight to operate the blower of a vehicle's A/C system.
solder: An alloy (mixture of metals) that has a relatively low melting point compared to other metals. It comes in roll form for easy application to a joint.
soldering: Involves using heat and molten solder to join electric components or wires.
soldering gun: A trigger-operated tool equipped with a transformer that sends high current through a high-resistance tip to generate heat for melting solder on hot electrical wires. It is more powerful and produces a stronger bond than a soldering iron.
soldering iron: A tool consisting of a heating element, heated tip, and handle. The heated tip melts electrical wires so solder can be used to join them. Its tip is also generally smaller and more suited for delicate work than the tip on a soldering gun.
soldering pick: Tool used to scrape corrosion from components before solder is applied. It can also be used to help hold or pin down small components while soldering.
soldering sponge: Water-soaked sponge used to clean the tip of the soldering gun or iron and various holding devices.
soldering torch: Tool that burns butane gas to generate heat for soldering wires and electric components together.
solenoid: An electrically operated magnetic device used to operate some unit. An iron core is placed inside a coil. When electricity is applied to the coil, the iron core centers itself in the coil and, as a result, it will exert some force on anything it is connected to.
solenoid diesel injector: Similar to a solenoid fuel injector but the body of the injector must be machined from thicker metal with larger internal passages to carry even more fuel pressure than direct gasoline injection.
solenoid disc: Disc that is pulled into the coil windings of the starter solenoid when the ignition key is turned on, completing the battery-to-starter circuit by touching both of the high-current terminals.
solenoid fuel injector: Type of electronic fuel injector that uses a small set of coil winding to produce an electromagnet inside the injector housing. When current energizes this electromagnet, it pulls the fuel valve open.
solenoid valve: A solenoid-operated air valve in an electronic height control system that can release air pressure from the system.
solenoid winding: Metal wire loop in the solenoid that conducts a small amount of battery current when the ignition is turned on.
solid wire: Inflexible wire with a single conductor inside its plastic insulation.
solvent gun: A type of blowgun with an attached solvent reservoir. It is used to spray solvent on large parts during cleaning.
sound system: System that includes many audio devices, such as an AM-FM stereo, compact disc player, satellite radio, or mp3 interface.
space saver spare: See *compact spare tire*.
spare tire: An extra wheel and tire assembly stored in or on a vehicle that can be installed if the vehicle has a flat tire.
spark ignition engine: An engine that uses an electric arc at the spark plug to ignite the air-fuel mixture. Gasoline engines are examples.
spark intensity test: Test that measures the brightness and length of the electric arc (spark) produced by the ignition system. It provides a quick and easy way of checking the general condition of the ignition system. It is also called a spark test.
spark knock: Engine combustion problem caused by the spark plug firing too soon in relation to the position of the piston.
spark line: Oscilloscope line showing voltage needed to maintain an arc across the spark plug gap.
spark plug: Part of an ignition system that converts high voltage into an electric spark or arc in the engine combustion chamber to burn the engine's fuel.
spark plug cleaner: Air-powered device that blasts the plug tip with abrasive to clean spark plugs.
spark plug gap: The spacing between the side electrode and the center electrode of a spark plug.
spark plug heat range: A rating of the operating temperature of the spark plug tip.
spark plug reach: The distance between the end of the spark plug threads and the seat or sealing surface on the plug. This determines how far the plug extends through the cylinder head.
spark plug wire: Wire that carries coil voltage from a side terminal of the distributor cap to a spark plug.
spark test: See *spark intensity test*.
spark tester: Device used to check ignition system output voltage. It looks like a spark plug with a very wide air gap and a ground wire.

Copyright Goodheart-Willcox Co., Inc.

spark timing: See *ignition timing.*
speaker: Audio device that uses a permanent magnet and a coil of wire mounted on a flexible diaphragm to convert electricity into motion and sound.
specialized technician: An expert technician in a specific area or system of automotive repair.
specialty shop: An automotive service facility that concentrates in one type of repair work, such as an exhaust or transmission shop.
speed-sensitive power steering: See *proportional rack-and-pinion power steering.*
spider: Welded center section of a drop-center wheel that bolts to a vehicle wheel hub.
spider gear: Idler and axle bevel gears in a differential that drive the rear axles of a vehicle. They are also referred to as differential gears.
spillback ball: Large "ping-pong-type" ball in the filler neck of a fuel tank assembly to prevent fuel from leaking out of the vehicle during fill-ups.
spindle: Shaft extending outward from the steering knuckle or the suspension system that holds the hub and wheel bearings.
spindle adjusting nut: Nut threaded on end of a spindle for adjusting the wheel bearing.
spin-on oil filter: A sealed unit having the element permanently enclosed in the filter body. This is the most common style automotive oil filter.
spiral bevel gear: A variation of a bevel gear in which the gear teeth are curved.
splash lubrication: Term for a style of lubrication where oil is distributed to needed areas by spraying or splashing.
splash oiling: Oil distributed to needed areas by spraying or splashing.
spongy brake pedal: Brake pedal that feels like it is connected to a spring or a rubber band.
spool control valve: Valve in a power steering gearbox or gear housing that routes oil to the power cylinder.
spool valve: Valve used to redirect fluid flow to different locations in a hydraulic circuit.
spray pattern: Term for fuel shape and consistency as it is discharged from the nozzle of a fuel injector. It should be a narrow, cone-shaped mist of fluid for best combustion.
spray-on gasket solvent: Solvent applied to soften a gasket so that it can be scraped off more easily.
spring bind: Condition caused when a valve spring's coils hit each other from over-compression, stopping additional compression and valve opening action.
spring closed length: The length of a valve spring when installed on the engine with the valve closed.
spring fatigue: A weakening of the strength/resistance of a spring that occurs after prolonged service or damage.
spring free length: Total length of a spring in its uncoiled position. For example, the length of a valve spring when removed from the engine.
spring open length: The length of a valve spring when installed on the engine with the valve fully open.
spring rate: The stiffness or tension of a spring, or the amount of weight needed to compress or bend a spring.
spring tension: The stiffness of a valve spring.
sprocket: Contoured gear or wheel that meshes with a chain or belt.
sprung weight: The weight of all the parts of the vehicle that is supported by the springs and suspension system.
spun rod bearing: A bearing that has been hammered out flat and damaged with the outer part of the bearing still rotating inside of the connecting rod bore.
spur gear: A gear that has its teeth cut parallel to a gear shaft centerline.
squish area: The area between the piston head at TDC and the cylinder head. This area makes up the combustion chamber.
stability control system: Electronically links the steering, suspension, braking, and traction control systems together to prevent a loss of vehicle control and skidding when cornering at high speed.
stabilizer bar: See *sway bar.*
stacked pattern: See *raster pattern.*
stake: Term for denting or bending certain types of fasteners whose edges can be bent downward into a slot to secure it on a shaft.
staking: Making a small dent in cylinder head metal next to a valve seat to hold it in place after replacement.
stall speed: Highest speed of impeller rotation in a torque converter without rotation of the turbine.
stall test: Method used to shop-test for transmission slippage or a malfunctioning torque converter in an automatic transmission.
stalling: Condition in which the engine suddenly stops running, or dies.
standard bearing: Bearing designed with the original dimensions specified by an engine manufacturer for a brand new and unmachined crankshaft.
star configuration: Computer network configuration in which one main processing computer and several less complex computers work as a network.
star wheel: Screw-type brake shoe adjusting mechanism.
start switch: See *ignition switch.*
starter armature: System that supports starting motor windings and strengthens their magnetic fields to produce the high torque and high speeds necessary to crank the engine.
starter current draw test: Test that measures that amount of current used by a vehicle starting system.
starter ground circuit test: Test for problems in the circuit between a starting motor and a negative battery terminal.
starter relay: Device that when closed, accepts a small current flow from the ignition switch or ECM to handle a slightly larger current flow to the starter solenoid.
starter shim: Thin metal strip used to adjust clearance between a starter motor pinion gear and the flywheel ring gear.
starter solenoid: High-current relay that establishes an electrical connection between the battery and the starting motor.
starter-actuated solenoid: Solenoid that completes the battery-to-starter circuit and also operates the pinion gear. It has a plunger that moves a shift lever to engage the pinion gear.
starting headlight test: Quick test that involves turning the headlights on while attempting to start a vehicle. Depending on what the headlights and starter do as the engine is cranked, the test can give a general idea of the starter system problem.
starting motor: High-torque electric motor used to turn the gears at the engine flywheel. It converts electrical energy from the battery into mechanical energy to crank the engine.
starting motor rebuild: Process of repairing a damaged or worn-out starter motor. This involves disassembly, cleaning, inspection, replacement of worn or damaged parts, polishing the commutator, lubrication, and reassembly/reinstallation.
starting system: Electric motor and other components used to rotate the engine until it starts.
states of matter: Vapor, liquid, and solid.
static imbalance: Condition in which a tire's weight mass is not evenly distributed around the axis of rotation. This condition is characterized by up-and-down vibration as the tire's weight mass tries to bring the tire back into balance.
stator: A small hub in a torque converter that improves oil flow. *Also,* a stationary set of wire windings that surrounds a rotor in a motor-generator or an armature in an alternator.
stator shaft: See *stator support.*
stator support: Stationary splined tube in a torque converter that supports the input shaft. It is also called a stator shaft.
steam cleaner: Machine that heats water into steam for removing heavy deposits of dirt, grease, and oil from the outside of large automotive part assemblies without chemicals.
steel rule: Measuring tool used to make straight-line measurements accurate to about 1/64" (0.5 mm). It is also referred to as a scale.
steel shell: Part of a spark plug that supports the other parts of the plug and has threads for screwing the plug into the engine cylinder head.
steering angle sensor: Part of a stability control system that measures how sharply the steering wheel is rotated to the right or left.
steering axis inclination: The angle, away from the vertical, formed by the inward tilt of the ball joints, king pin, or MacPherson strut tube.
steering column: Hollow tube that supports a steering wheel and a steering shaft.
steering column assembly: Assembly consisting of a vehicle steering wheel, steering shaft, column (outer housing), ignition key mechanism, and, sometimes, a flexible coupling and a universal joint.
steering damper: Oil-filled shock absorber positioned between a vehicle frame and center link in some parallelogram steering linkage arrangements.

Copyright Goodheart-Willcox Co., Inc.

steering feel: The feedback of road imperfections vibrating through a steering wheel.
steering gear reduction: See *gearbox ratio.*
steering gearbox: Mechanism that connects with the steering shaft to multiply turning torque and change turning motion into a straight-line motion to the left or right for moving the steering knuckles.
steering knuckle: Steering part that holds the wheel bearings, axle stub shaft, and hub.
steering linkage: Components connecting the steering gearbox to the steering knuckles and wheels.
steering pinion gear: Gear rotated by a steering wheel and steering shaft with teeth that mesh with the teeth on the rack in a rack-and-pinion steering system.
steering ratio: See *gearbox ratio.*
steering sensor: A sensor that provides wheel orientation and speed data to the computer in an electronic shock absorber system.
steering shaft: A two-piece shaft that transfers turning motion from the steering wheel to the gearbox.
steering system: The components that let the driver change the direction of a vehicle.
steering system inspection: Process of checking for excessive wear and movement in the operating parts of a vehicle steering system.
steering wheel: Wheel turned by a driver to rotate a steering shaft that passes through the steering column and vehicle firewall.
steering wheel play: The amount of movement in a steering wheel before it starts to move steering rack or linkage. Steering problems can arise if this is not within specifications.
steering wheel pull: A noticeable wheel tug, either right or left, that is felt through a steering wheel strain in one direction.
steering wheel touch control: Switches mounted on a steering wheel to manipulate some vehicle systems with minimal distraction.
stereo amplifier: An electronic component for radio speakers. It increases the current output of the radio and/or compact disc player for driving the speakers more efficiently. It is also called a power booster.
stethoscope: A listening device that amplifies the sound generated by internal parts. It consists of a probe connected to earpieces.
sticktion: Term describing the initial resistance to force between rubber seals or bushings and metal parts. It can cause noises between parts and affect vehicle ride smoothness.
stiff clutch pedal: Problem that occurs when part of a clutch release assembly is not moving in sync. The pedal feels tight, requiring more force to be applied to it to release the clutch.
stoichiometric fuel mixture: Chemically correct air-fuel mixture (14.7 parts air to 1 part fuel) that given constant engine conditions, burns as efficiently as possible during combustion.
stoichiometric mode: One of three modes for a direct electronic fuel injection system that produces a theoretically homogenous (equally mixed and dispersed) mixture of fuel and air.
stone dressing tool: Diamond-tipped cutting tool used to smooth and true the face of a seat stone.
stool creeper: A stool with wheels that allows a technician to sit while working on vehicle parts that are near the ground.
stoplight switch: A spring-loaded electrical switch that operates the rear brake lights of the vehicle when the brakes are actuated.
storage: Collection of programming, data, operating parameters, trouble codes, and other information that a computer accumulates and remembers on its memory chips.
stranded wire: Flexible wire that has numerous individual wires twisted together inside the insulation.
strap: See *retaining collar.*
strategy-based diagnostics: See *systematic approach.*
stratified charge combustion chamber: A combustion chamber design in which a rich air-fuel mixture is first ignited in a small chamber connected to the main chamber. These flames instantaneously ignite a lean air-fuel mixture waiting in the main chamber.
stratified charge mode: One of three modes for a direct electronic fuel injection system that uses a small charge of fuel injected into the combustion chambers during the end of the compression stroke.
stress testing: The use of heat, cold, or moisture to simulate extreme operating conditions encountered by vehicle components, parts, and systems.
structural oil pan: Oil pan designed to add strength to an engine bottom end and cylinder block with ribs and bosses to help support the crankshaft and main bearings.
strut assembly: Suspension component that consists of a shock absorber, a coil spring (most types), and an upper damper unit. It replaces the upper control arm.
strut bearing: A ball bearing that allows the shock-and-spring assembly to rotate for steering action; only used on the front of the vehicle.
strut rod: Rod that fastens to a control arm and vehicle frame to keep the arm properly oriented.
strut rod nut: A hex nut that screws on top of a shock absorber rod to hold it in an upper strut retainer.
strut shock absorber: A piston operating in an oil-filled (or oil and gas) cylinder to prevent coil spring oscillations.
strut spring compressor: Screw-type tool used to compress strut springs during removal and installation.
stub axle: Two short outer axles connected to a long central axle shaft through the CV joints. The stub axles connect to the transaxle and the wheels.
stuck valve: Condition in which a valve stem rusts or corrodes and locks in the valve guide. It is also called a frozen valve.
stud puller: Tool used to remove studs and bolts broken off above the surface of a part. It is also called a stud wrench.
stumbling: Condition in which an engine repeatedly loses power and causes the vehicle to jerk upon acceleration or highway cruising.
subtraction: Arithmetic process of taking away a certain number or quantity from another.
suction service valve: An A/C service valve that is located at the inlet to the compressor, in the system low side.
suction side: See *low side.*
suction throttling valve: An A/C system control that is used with the expansion valve to control evaporator temperature.
sump: The lowest area in an oil pan where oil collects.
supercharger: A belt-driven compressor that pumps air into an engine's intake manifold. Superchargers are dependent on engine speed and are most efficient at high engine speeds.
supercharger assembly: The components of a supercharger. The supercharger assembly consists of a housing, rotors, two timing gears, an extension housing, and a drive pulley.
supercharger belt: Belt attached to a supercharger drive pulley that drives the rotors inside the supercharger.
supercharger bypass valve: Valve that allows boost pressure from a supercharger to flow back into the intake air during low engine loads. During high demand, the valve closes so all boost pressure flows into the engine.
supercharger cooling system: System that uses liquid coolant passed through an intercooler positioned on the supercharger to keep the blower intercooler temperature cooler than the engine's operating temperature.
supercharger drive pulley: Pulley that draws power from an engine crankshaft through a large serpentine belt or supercharger belt to drive a supercharger.
supercharger extension housing: Bolted to the front of the supercharger housing, it encloses a shaft that connects one of the supercharger timing gears to the drive pulley.
supercharger housing: Large aluminum enclosure for the rotors, rotor bearings, and drive gears of a supercharger.
supercharger rotor: Meshing, twisted blades or fans that spin to produce pressure inside a supercharger housing.
supercharger timing gear: Gears that keep the two rotors timed and spinning at the same speed. One is driven by the drive pulley; the other is driven by the first timing gear.
superheat switch: An A/C system control that senses low system pressure and high compressor temperature, and sends current to the thermal limiter.
surface ignition: See *preignition.*
surging: Condition in which engine power fluctuates up and down.
suspension control module: Computer that controls the electronic suspension system. It uses sensor inputs to issue output commands to electrical devices that control air pressure or hydraulic fluid flow to suspension parts.
suspension leveling system: Suspension system designed to keep vehicle level and at proper height, even when carrying a heavy load.

Copyright Goodheart-Willcox Co., Inc.

suspension system: Components that let vehicle wheels move up and down without body movement.
suspension system spring: Spring that compresses and extends as a vehicle travels over road hazards to absorb vibrations and smooth the ride.
sway bar: A transversely-mounted spring steel bar that is installed to control body lean during cornering. The ends of the sway bar are attached to the lower control arm on each side of the vehicle, and the center is attached to the frame. It is also called a stabilizer bar.
sway bar link: Metal bar that connects a sway bar to a suspension control arm.
swing axle: Flexible axle with a U-joint mounted on each end to allow for up-and-down suspension movement. They are used on vehicles with the differential mounted solidly on the frame.
swirl combustion chamber: The shape of the intake and exhaust ports and the combustion chamber roof create a swirling effect to help mix the air-fuel mixture.
switch: An electrical device used to connect or disconnect the power supply in a circuit.
switch diagnostic test: A test that involves activating various switches while using a scan tool to determine if the switch is working normally.
switching sensor: See *manual transmission gear sensor.*
synchronizer: Assembly of hub, sleeve, and other components that brings certain transmission gears to the same rotational speed as the output shaft before sliding in mesh with them to lock them to the output shaft.
synthetic oil: Oil manufactured by further processing and blending crude mineral oils together with about 25% more synthesized (modified) mineral oils.
system: A set of fitted parts and assemblies designed to complete a specific function.
system wiring diagram: A diagram that contains only the components and wires for a particular circuit, such as the ignition system circuit.
systematic approach: Problem-solving approach that involves using a knowledge of automotive system theory and a logical process of elimination to find the source of a vehicle problem. It is also called strategy-based diagnostics.

T

tach: Abbreviated name for a tachometer.
tach-dwell meter: A tachometer and a dwell meter combined into one instrument. The tachometer is for measuring engine speed (rpm). The dwell meter measures current flow as compared to degrees of engine crankshaft rotation.
tachometer: Device used to measure engine speed in rpm.
tail shaft housing: See *extension housing.*
tailpipe: Steel tubing that carries exhaust from a muffler to a point at the rear or side of a vehicle, where it can be dispersed.
tandem master cylinder: See *dual master cylinder.*
tap: Tool for cutting threads inside a hole.
tape measure: A flexible roll of measuring tape that extends to several feet or meters in length and is used for long measurements. It is also called a tape rule.
tappet: See *valve lifter.*
tapping screw: See *sheet metal screw.*
taxable horsepower (thp): A general rating of engine size focused on cylinder size measurements used to find the tax placed on a vehicle.
teardown: The general method of disassembly of an engine. Specific teardown procedures will vary by engine.
technical bulletin: See *technical service bulletin.*
technical service bulletin (TSB): A service bulletin published by auto manufacturers and equipment suppliers that helps a technician stay current with recent technical changes, repair problems, and other service-related information. It is also called a technical bulletin.
technology: The application of math, science, physics, engineering, and other subjects to a manufacturing or production process.
telescoping gauge: Tool used in conjunction with a micrometer to measure internal part bores or openings.
temperature warning light: Dashboard light that illuminates to inform the driver when the engine is overheating.
tensile strength: The amount of pull a fastener can withstand before it breaks.
terminal: A connecting point in an electrical circuit.
test indicator: See *battery charge indicator.*
test light: Piece of test equipment that shows the presence of current by lighting a small light.
thermal efficiency: A comparison of the amount of fuel burned to the amount of horsepower output.
thermal limiter: An A/C system control that receives current from the superheat switch when it senses low system pressure and high compressor temperature to prevent damage.
thermal runaway: Occurs when a transistor is driven too hard (too much output current is controlled by the transistor). The output of the transistor will fluctuate as the transistor's thermal capacity is exceeded.
thermistor: Type of resistor that undergoes internal resistance changes as temperature fluctuates.
thermo switch: See *fan switch.*
thermometer: A tool/gauge for measuring temperature.
thermostat: A temperature sensitive device used in cooling systems to control coolant flow in relation to temperature.
thermostat housing: A pot metal, aluminum, or plastic enclosure that holds a thermostat in place on an engine.
thermostat rating: Information stamped on a thermostat to indicate the operating (opening) temperature of the thermostat.
thermostatic cycling switch: Turns the compressor on and off to maintain the correct evaporator temperature (approximately 32°F or 0°C).
thermostatic fan clutch: Type of fan clutch that contains a temperature-sensitive, bimetallic spring to control fan action.
thread chaser: Tool used to clean and remove burrs and other damage from threads.
thread repair insert: Item screwed along the inside walls of a damaged threaded hole. The insert replaces the damaged threads and allows the use of the original size fastener.
three-angle valve job: Type of valve seat narrowing that uses three different stone angles when grinding.
three-phase ac power: Power system used in an HV motor-generator when it must propel the vehicle. It consists of three single-phase alternating voltage waves flowing through three conductors (HV power cables) at different intervals in time.
three-valve combustion chamber: Combustion chamber with two intake valves and one exhaust valve. It nearly matches the performance of a four-valve chamber, but with lower costs and increased reliability.
three-way catalytic converter: A catalytic converter capable of reducing amounts of HC, CO, and NO_X from exhaust gases.
throttle actuator: Part of a cruise control system that physically moves the engine throttle lever to control engine power and resulting vehicle speed.
throttle body injection system (TBI): The first electronic fuel injection system used on passenger cars with injector nozzles mounted in a throttle body assembly located on top of the engine.
throttle position sensor (TPS): A variable resistor connected to the throttle plate shaft that produces different current levels for different throttle positions.
throttle safety release: Electric clutch release mechanism that returns an engine to idle even if the engine throttle actuator fails or loses power.
throttle valve: A valve controlled by linkage from the engine throttle plates or by a vacuum modulator operated from engine manifold vacuum. It controls fluid pressure to the shift valve according to the distance the throttle is moved.
throttle-by-wire system: System of components that move engine throttle valves electronically instead of using conventional mechanical linkage from an accelerator pedal. It is also called a drive-by-wire system.
throw-out bearing: See *release bearing.*
throw-out lever: See *clutch fork.*
thrust spring: Spring that preloads the rack-and-pinion gear teeth inside a gear housing to prevent excessive gear backlash.
thrust washer: A bronze or hardened steel washer placed between two moving parts to prevent longitudinal movement.
tie-rod: Inner and outer steel rods that fasten and transfer turning force from a rack or center link to steering knuckles in a steering system.
tie-rod assembly: Term for the combined components of a tie-rod.

Copyright Goodheart-Willcox Co., Inc.

tilt steering column: Steering column equipped with a universal joint at the top that allows the top half of the column and the steering wheel to be positioned at different angles. It is also called a tilt steering wheel.
tilt steering wheel: See *tilt steering column.*
timed injection system: Type of fuel injection that sprays fuel into the engine during intake or compression strokes, in relation to piston and valve action.
timing advance: A method of ignition timing that fires the spark plugs on the engine's compression strokes relatively sooner than the specified manufacturer's timing.
timing belt: A flexible cogged (square) toothed belt used to rotate the camshaft(s).
timing belt drive mechanism: Mechanism, that consists basically of a crankshaft sprocket, camshaft sprocket, timing belt, and belt tensioner, used to drive a camshaft on overhead camshaft engines.
timing belt sprocket: A crank sprocket is keyed to a crankshaft snout. A camshaft sprocket bolts to the front of a camshaft. Cast iron or aluminum belt sprockets have timing marks that align with engine points to correctly open valves.
timing belt tension: Degree of tightness of an engine timing belt. If too loose, the belt could vibrate in service and fly off its sprockets. If too tight, the timing belt could break.
timing chain: Sprocket-and-chain combination that transfers rotation from the crankshaft to the camshaft. It may also mesh with other sprockets to power other devices.
timing cover: See *engine front cover.*
timing gear: Calibration-marked meshing gears on a crankshaft and camshaft that rotate the camshaft at half crankshaft speed.
timing gear backlash: The amount of clearance between timing gear teeth, which is often used as an indication of wear.
timing gear runout: Unwanted gear wobble, or side movement, during rotation. A dial indicator is used to measure the value.
timing mark: Calibrating mark on timing gears or other timing devices. They are used to set engine timing.
timing retard: A method of ignition timing that fires the spark plugs on the engine's compression strokes relatively later than the specified manufacturer's timing.
tinning: A process used to clean and prepare the surface of the soldering gun tip and the electric components. It consists of placing a thin coat of solder on the tip or parts.
tire: A treaded, rubber-covered carcass made of steel and fiber cords. It provides vehicle traction on a road surface and a cushion between the wheels and a road.
tire changer: See *tire changing machine.*
tire changing machine: Machine that uses manual and pneumatic mechanical components to force a rubber tire on or off a metal wheel/rim. It is also called a tire changer.
tire impact damage: Punctures, cuts, tears, and other physical tire injuries. It is also referred to as road damage.
tire inspection: Process of looking for excessive wear, improper inflation, or physical damage on a vehicle's tires.
tire load index number: Numerical representation (in pounds or kilograms) of the weight a tire can carry without failure.
tire maintenance: Service that includes periodic inspection, checking of inflation pressure, and rotation of vehicle tires to prevent problems.
tire marking: Writing on a tire sidewall that gives information about tire size, tire model, load-carrying ability, inflation pressure, number of plies, speed rating, manufacturer, etc.
tire pressure gauge: Air pressure gauge used to measure tire inflation pressure.
tire pressure monitor calibration tool: A handheld device that communicates wirelessly with each vehicle tire pressure sensor to accurately regulate the TPMS for proper operation.
tire pressure monitoring system (TPMS): System that monitors tire pressure with sensors and alerts the driver if one or more of the vehicle's tires is under- or overinflated.
tire rotation: Moving tires from side to side or from front to back to help equalize tire wear, making the tires last longer.
tire runout: Tire movement or wobble that is caused by a faulty tire (ply separation or manufacturing defect).
tire size: Tire marking given on its sidewall as a letter-number sequence.
tire speed rating: Tire marking indicating the maximum allowable sustained road speed a tire can safely withstand without failure.
tire temperature resistance: Tire marking indicating a tire's ability to resist heat buildup. It is given as an A, B, or C rating, with an A rating resisting temperature buildup the best.
tire traction: Tire marking for a tire's ability to grip a road surface. It is given as an A, B, or C rating, with an A rating providing the most traction and a C rating the least.
tire vibration: Tire problem commonly caused by an out-of-balance condition, ply separation, excessive tire runout, a bent wheel, tire stiffness variation, or tire cupping.
tire wear pattern: Areas of tire tread that are worn off, which can provide information on causes of the wear.
titania oxygen sensor: Type of oxygen sensor that uses a thick film of titania to detect the amount of oxygen present in exhaust gases. The sensor varies its internal resistance to signal the ECM.
toe: Determined by the difference in distance between the front and rear of the left- and right-hand wheels.
toe adjustment sleeve: Threaded sleeve provided for changing the length of a tie-rod assembly during wheel alignment.
toe-in: When the wheels are closer at the front than at the rear. Toe-in causes the wheels to point inward at the front.
toe-out: When the wheels are farther apart at the front than at the rear. Toe-out causes the front of the wheels to point away from each other.
toe-out on turn: The amount the front wheels toe-out when turning corners. It is also called a turning radius.
tool holder: Trays, racks, pouches, or other organizers of small tools and parts.
toolbox: Metal cabinet, chest, or carrying box that stores and protects a technician's tools when not in use.
toolroom: A shop area where large pieces of repair equipment, shop tools, and repair supplies are stored.
top dead center (TDC): The point of travel where the piston is at its highest point in the cylinder.
torque: Any turning or twisting force.
torque converter: Fluid-filled hydraulic coupling that acts as a clutch on an automatic transmission/transaxle and transmits and multiplies engine torque.
torque multiplication: Increasing engine torque through the use of a torque converter or gears.
torque specification: Tightening value provided by the vehicle manufacturer for certain fasteners. A general torque chart is also available when average bolt tightening values can be used.
torque steer: Undesired turning effect due to the difference in drive angles in an unequal-length drive axle system causing one wheel to receive more torque during heavy acceleration.
torque tube driveline: Type of driveline with a solid steel drive shaft enclosed in a large hollow tube that forms a rigid part of the rear axle housing. This keeps the transmission, drive shaft, and differential in alignment without flexing over rough surfaces. Late-model vehicles have replaced this style with the Hotchkiss driveline.
torque wrench: A calibrated wrench designed to measure the amount of turning force applied to a threaded fastener.
torque-to-yield: A bolt tightening method in which a bolt is first tightened to a specific torque and then turned a certain number of degrees. This stretches the bolt to its yield point.
torque-to-yield bolt: Type of bolt that is first tightened to a specified torque. Then, using a torque angle gauge, the bolt is turned a specified number of degrees beyond the torque point. This type of bolt must be replaced when reassembling the engine.
torque-to-yield specification: Set of manufacturer's instructions for tightening certain fasteners. The fastener is first tightened to a specified torque. Then, using a torque angle gauge, the fastener is turned a specified number of degrees beyond the torque point.
torquing: The process of properly tightening a fastener with specifications.
Torsen differential: A type of locking differential that uses complex worm gearsets, with worm gears driving worm wheels.
torsion bar: Spring steel rod that functions as a spring and absorbs shocks by twisting. One end of the bar is attached to the frame and the other end is attached to the control arm.

Copyright Goodheart-Willcox Co., Inc.

torsion bar suspension: A suspension system that contains torsion bar springs instead of coil springs and can be height adjusted with adjustment bolts.
torsion spring: Small coil spring positioned near the inside of a clutch disc that helps absorb shock and vibration that occurs when the disc first engages with the flywheel. It is also called a damping spring.
total misfire: Readout averaging the number of engine cylinder misfires recorded during the last 200 crankshaft revolutions.
trace: Pattern of circuit voltages.
track rod: Metal rod connected on one end to a rear axle and on the other end to the vehicle frame to prevent axle side-to-side movement when cornering. It is also called a lateral control rod.
track width: Distance between the centerlines of two wheels (right and left) on the same axle.
tracking: Refers to the position or direction of the two front wheels in relation to the two rear wheels.
traction control system (TCS): Electronically controls the brakes, differential, engine, and transaxle to help reduce tire spin upon acceleration on slippery pavement.
trailing edge: See *falling edge.*
tram gauge: Wheel alignment tool that is used to compare the distance between the front and rear of a vehicle's tires for checking toe adjustment.
transaxle: A combination of transmission and differential in one case, used on front-wheel drive vehicles.
transaxle case: An aluminum housing that encloses and supports the parts of the transaxle.
transaxle differential: Gear assembly that transfers power to the front axles and wheels while allowing one wheel to turn at a different speed than the other.
transduce: To change from one form to another.
transducer switch: A type of switch in which its internal resistance changes with a change in a condition.
transfer case: Transmission-driven gearbox that provides driving force to both front and rear drive shafts on a four-wheel drive vehicle.
transformer: An electrical device that uses two sets of coils to transform voltage and current to higher or lower levels.
transistor: A semiconductor device that can be used as a switch or an amplifier.
transmission case: Aluminum or cast iron housing surrounding and supporting a transmission.
transmission control module (TCM): Name for a computer that controls the functions of an electronic-controlled transmission.
transmission control sensor: Electronic sensor that monitors a variable component of a transmission and sends signals to a transmission control module.
transmission fluid varnish: Term for a brown, glue-like substance that coats internal parts of a transmission. It is formed from broken-down transmission fluid and can cause major transmission problems.
transmission gear: Term for the gearsets and gear assemblies within a transmission that transfer power through the transmission. These gears include input, output, countershaft, reverse, and planetary gearsets.
transmission jack: Adjustable jack used to support a transmission or transaxle during removal and installation.
transmission oil cooler: Separate tank formed inside radiator tanks that dissipates heat from automatic transmission or transaxle fluid.
transmission oil pump: Pump located near the front of a transmission assembly that produces the necessary pressure and lubrication to operate an automatic transmission.
transmission pan: Steel or cast aluminum tub bolted to the bottom of a transmission case that acts as a collection unit and reservoir for transmission oil.
transmission rear seal: Seal that rides on a slip yoke and prevents fluid leakage from the rear of the transmission.
transmission shaft runout: Vibration or side-to-side movement of a worn or bent transmission shaft during operation. Irregular gear tooth wear can be a cause.
transmission solenoids: Actuators in the valve bodies of an electrically controlled automatic transmission. With current from a control module, it can act on a control valve to change hydraulic pressure for various operating conditions.
transponder key: Theft deterrent ignition key containing an electronic chip. Each time the key is turned in the ignition, it generates a coded signal that must be recognized by the transponder module in order for the vehicle to start.
transverse: Crosswise; term used to identify an engine rotated 90° from the traditional longitudinal mounting.
travel: Term for required movement/action of suspension system springs.
tread: Outer surface of tire that contacts the road.
tread wear rating: Measure of a tire's resistance to wear. Tread wear ratings range from 100 to 500. A tire with a rating of 200 should last about twice as long as a tire rated at 100.
trickle charger: See *slow charger.*
trigger wheel: See *sensor rotor.*
tripod CV joint: A type of constant velocity joint used on the inner part of a CV axle. It is triangular shaped and has three sets of needle bearings and balls on a spider assembly.
trouble code chart: Diagnostic aid that lists the problem encountered for each code.
trouble code conversion: Process of a scan tool automatically converting a number code into abbreviated words that explain a potential problem.
troubleshooting chart: Diagnostic flowchart that provides step-by-step procedures to test automotive systems.
tubeless tire: Tire that does not have a separate inner tube.
tumbler: Lock mechanism on an ignition switch.
tuner: Device that is used to adjust to different radio frequencies (stations).
turbine: The driven fan assembly in a torque converter.
turbine housing: Outer enclosure that routes exhaust gases around a turbine wheel in a turbocharger.
turbine shaft: See *input shaft.*
turbine wheel: Exhaust-driven fan that turns the turbo shaft and compressor wheel of a turbocharger.
turbo: See *turbocharger.*
turbo blow off valve: Air pressure release valve to limit maximum boost pressure as the engine throttle valves are closed rapidly for deceleration. It is also called a dump valve.
turbo lag: Short delay before a turbocharger develops sufficient boost.
turbo shaft: Steel shaft, passing through the center of the bearing housing, that connects the turbine and compressor wheels.
turbo shaft end play: Lengthwise movement between a turbo shaft and its connections. It should be .001″ (0.03 mm) to .003″ (0.08 mm).
turbo shaft radial runout: Variation in the radius of a turbo shaft. It should be .003″ (0.08 mm) to .006″ (0.15 mm).
turbocharger: A turbine device that utilizes exhaust pressure to increase the air pressure going into the engine cylinders. It can also be called a turbo.
turbocharger boost pressure: Maximum allowable intake manifold pressure a turbo system should build under a full engine load.
turbocharger cooling system: System that forces coolant through the turbo bearing housing to keep the turbo from overheating under prolonged high boost.
turn signal system: Vehicle system consisting of a fuse, turn signal switch, flasher unit, turn signal bulbs, indicator bulbs, and related wiring. When activated, the right or left side turn lamps flash, along with turn indicator lights in the instrument panel or on the fenders.
turning: The removal of a thin layer of metal from a rotor or drum to restore the surface finish. It is also referred to as cutting or machining.
turning plate: A tool used to eliminate stresses in the suspension and linkage when turning the wheels during alignment checks and adjustment.
turning radius: See *toe-out on turn.*
turning radius gauge: Wheel alignment tool that measures how many degrees the front wheels are turned right or left.
turns ratio: A ratio of the number of windings or wraps of wire in each transformer coil in a transformer.
twin turbocharger system: See *sequential turbocharger system.*
twisted-pair conductor: Type of conductor with two insulated wires that are wound, or twisted, into a spiral to carry data signals between computers.
twisted-pair wire: Two insulated wires that are wound, or twisted, around each other.

Copyright Goodheart-Willcox Co., Inc.

two-bolt main block: Design with two cap screws holding each main bearing cap to a cylinder block.
two-channel ABS: An ABS channel that has two separate hydraulic circuits controlled by the electro-hydraulic modulator.
two-gas exhaust analyzer: Exhaust analyzer that can only measure the amount of hydrocarbons (HC) and carbon monoxide (CO) in a vehicle's exhaust gases.
two-stroke-cycle engine: An internal combustion engine that requires one revolution of the crankshaft and two piston strokes (one upward and one downward) to complete the intake, compression, power, and exhaust events.
two-way catalytic converter: A catalytic converter capable of reducing amounts of HC and CO from exhaust gases.
type A misfire: Engine misfire that is severe enough to cause catalytic converter damage. This type of misfire will trip a trouble code and illuminate the MIL.
type B misfire: Engine misfire that causes an increase in emissions but not catalytic converter damage.

U

U-joint: See *universal joint*.
umbrella valve seal: Rubber or plastic seal placed on a valve stem before the spring and retainer to seal the gap between stem and valve guide.
underinflation: Term for low air pressure within a tire, which can lead to problems including flexing sidewalls and a center tread section that does not wear.
undersize battery: A battery with a lower watt or amp rating than the battery it is replacing. It can cause starting motor performance and battery service life issues.
undersize bearing: Bearing designed to be used on a crankshaft journal that has been machined to a smaller diameter.
understeer: A vehicle steering issue in which the front tires lose traction while the rear tires retain traction as a vehicle goes through a corner. It appears as if the driver is not adequately turning the steering wheel.
unibody construction: A vehicle design in which the frame and body is one unit.
universal joint: A flexible joint that permits changes in driving angles between a driving and driven shaft. It is nicknamed a U-joint.
universal joint tool: Special tool or set of tools available for pressing universal joints apart and together. It can take the place of a vise during assembly or disassembly.
unlike charge: Opposite charged electrical fields that attract each other.
unsprung weight: The weight of all of the vehicle's parts not supported by the springs, such as wheels and tires.
upper spring seat: Metal plate with a flange to hold the upper end of a coil spring and a center hub that contacts the strut bearing.
upper strut retainer: Metal disc that secures the upper end of a strut assembly to a vehicle frame or unibody.

V

vacuum: Pressure lower than atmospheric pressure that is formed in an enclosed area.
vacuum bleeder tool: A tool that uses shop air pressure and the Venturi effect to produce suction in a brake fluid container and a small plastic hose connected to a brake system's bleeder screw.
vacuum bleeding: Method of brake bleeding that requires the use of a vacuum device to pull brake fluid through the hydraulic system.
vacuum booster: Uses engine vacuum or vacuum created by an auxiliary pump to help apply the brake pedal.
vacuum gauge: Gauge commonly used to measure negative pressure or vacuum (suction). It reads in inches of mercury (in/Hg) or metric kilograms per square centimeter (kg/cm^2).
vacuum hose diagram: Vehicle specific diagram showing the routing of all vacuum hoses.
vacuum leak: A leak (often with an accompanied hissing noise) commonly caused by deteriorated, broken, or loose vacuum hoses.
vacuum modulator valve: Valve that senses engine load based on engine manifold vacuum pressure. It mechanically changes throttle pressure to determine shift points.
vacuum motor: Large diaphragm that converts vacuum into motion.
vacuum pump: Engine-operated pump used to produce a vacuum for vehicle accessories. It is also a hand-operated pump used to test vacuum-operated devices.
vacuum suspended brake booster: Has vacuum on both sides of the piston or diaphragm when the brake pedal is released. Pushing down on the brake pedal releases the vacuum on one side of the booster. The difference in pressure pushes the piston or diaphragm for braking action.
vacuum switch: Routes engine vacuum to the correct vacuum motor. The vacuum motors then move the air doors.
vacuum test: Test that uses a vacuum gauge to measure intake manifold vacuum and indicate engine condition.
vacuum-pressure gauge: Gauge that can read and measure both negative and positive pressures.
valve adjustment: See *valve train clearance adjustment*.
valve body: Housing bolted to the bottom of a transmission containing most of the valves used in operation of an automatic transmission.
valve core: A threaded, spring-loaded valve that screws into a tire's valve stem and allows air to be added or expelled from a tire.
valve cover: A metal or plastic cover over the top of a cylinder head to prevent oil leakage.
valve face angle: The angle formed between a valve face and valve head.
valve float: A tendency for valves to remain partly open, especially at high speeds. It usually results from a weak or broken valve spring.
valve grinding: Grinding done to create a fresh, smooth surface on a worn or damaged valve face and stem tip.
valve grinding machine: Machine used to resurface valve faces and valve stem tips.
valve guide: A hole machined into the head to support the valves as they ride up and down. It may be machined oversized to accept a removable guide.
valve guide wear: Deterioration of a valve guide, which allows the valve stem to move sideways in the guide during operation.
valve keeper: Device that snaps into a groove in a valve stem. It is used to retain valve and spring assembly in the head.
valve lapping compound: An abrasive paste material used to check the valve-to-seat contact.
valve lash adjustment: See *valve train clearance adjustment*.
valve lifter: Component that is moved by the camshaft lobe and in turn moves the push rod or the rocker arm. It is also called a tappet.
valve overlap: Period in degrees of camshaft rotation in which both the intake and exhaust valves are partially open.
valve retainer: A specially-shaped washer that fits over the top of a valve spring to secure it on the valve stem.
valve retrusion: The head of a valve sinking into a cylinder head caused by extensive valve seat and face wear.
valve rotator: Device that turns an engine valve to prevent carbon buildup and hot spots.
valve seal: A seal that is placed over the valve stem to prevent oil leakage between the stem and the guide.
valve seat: Machined or installed metal surface on the intake and exhaust ports, against which a valve rests and seals.
valve seat angle: The angle formed by the face or contact surface of a seat.
valve seat machine: A specialized milling machine designed for valve guide and valve seat service.
valve seat reconditioning: Machining process using a grinding stone or carbide cutter to resurface cylinder head valve seats.
valve spring assembly: Assembly, consisting of a valve spring, a retainer, and two valve keepers, used to close a valve.
valve spring free height: The length of a valve spring in an uncompressed condition.
valve spring installed height: The length (or height) of a valve spring when installed on an engine with the valve closed.
valve spring seat: A cup-shaped washer installed between a cylinder head and bottom of a valve spring. It holds the bottom of the valve spring squarely on the head and valve stem.
valve spring shield: Thin metal shield that surrounds the top and upper sides of the valve spring and helps keep excess oil off the valve stem.
valve spring shim: Precise-thickness flat washer that fits under valve springs to reduce their installed height and maintain the correct spring tension.

Copyright Goodheart-Willcox Co., Inc.

valve spring squareness: Measure of a valve spring's centerline to its seating surface.
valve spring tension: The stiffness of a valve spring.
valve stem: The thin portion of an engine valve that is inside the head. The stem rides in the valve guide. *Also,* a rubber shaft pressed into a hole in the wheel of a tubeless tire to allow inflation and deflation. The stem is threaded near the top of its body to accept the valve core.
valve stem cap: A hardened steel cup that installs over a valve stem in a valve train. It is free to rotate on the tip to reduce friction and wear between the stem and rocker arm. *Also,* a metal or plastic cap that installs over a tire valve stem. It keeps the valve clean and prevents accidental tire deflation.
valve timing: Intervals at which valves open and close, determined by camshaft configuration.
valve train clearance adjustment: Process of changing valve clearance to vehicle/engine specifications to ensure proper opening and closing of engine valves for efficient combustion and exhaust emission. It is also called a valve lash adjustment or valve adjustment.
valve train noise: A light tapping or clicking sound produced by valves that are too loose in a valve train.
valves in receiver (VIR): Both the expansion valve and the POA valve are enclosed in the receiver-drier.
vane oil pump: Type of oil pump that uses sliding wipers within a housing to build oil pressure.
vapor lock: Condition caused by bubbles in fuel due to overheating. It can cause stalling, hard starting, or failure to start.
vaporization: See *vaporize.*
vaporize: Changing an element from a liquid to a gas (vapor).
variable camshaft timing: Allows engine oil pressure to operate hydraulic camshaft phaser sprockets and other hydraulic actuators in a valve train. Valve timing can vary based on engine rpm and load.
variable displacement engine: An engine that can deactivate cylinders to conserve fuel and reduce emissions.
variable dwell: Dwell timing in which the engine control module alters ignition coil dwell timing with changes in engine speed.
variable induction system: An intake system manufactured with a set of long and short intake runners. Based on engine speed, valves open one set of runners for either more torque (low speed, long runners) or more power (fast speed, short runners) from an engine.
variable transmission solenoid: Solenoid that uses different ECM current frequencies to control how far a spool valve opens or closes a fluid pressure passage.
variable valve timing engine (VVTE): Engine that can alter valve opening and closing independent of crankshaft rotation.
variable valve timing system: System that can alter valve opening and closing independent of crankshaft rotation. At low speeds, the valves function with a standard duration, but hold open longer to increase volumetric efficiency as engine speed increases.
variable vane turbocharger: Turbocharger that uses a set of hinged blades mounted inside the turbine housing to control exhaust gas flow over the turbine wheel or fan.
variable volume oil pump: Type of oil pump capable of building high oil pressure at idle and reducing pump volume per revolution at high engine speeds for better engine efficiency.
variable-ratio gearbox: Gearbox that changes the internal gear ratio as vehicle front wheels are turned from the center position, requiring fewer turns to move the wheel from full right to full left than a constant ratio gearbox.
vehicle collision: Normally results from driver error that causes the car or truck to hit other objects (vehicles, trees, retaining walls, etc.). It is also referred to as an accident.
vehicle cradle: A strong metal structure mounted at the lower front and sometimes the lower rear of the unibody structure.
vehicle degaussing: The process of removing any large magnetic field built up around the vehicle body structure. It is also called vehicle demagnetizing.
vehicle demagnetizing: See *vehicle degaussing.*
vehicle fluid: Fluids within an engine such as engine oil, coolant, brake fluid, transmission fluid, and other liquids that help keep a vehicle operating properly.
vehicle height: Distance from the ground to the highest point on a vehicle roofline.
vehicle identification number (VIN): Individual series of letters and numbers assigned to a vehicle by the manufacturer at the factory.
vehicle information section: Part of a vehicle inspection report that identifies the type of motor vehicle tested. It lists the license plate number, VIN, year, make, model, engine type, fuel type (gas or diesel), test number, and the type of emission test needed (OBD or non-OBD).
vehicle inspection report: Subsequent report given to a driver that summarizes why the vehicle either passed or failed its state-mandated emission test.
vehicle length: Distance from the outermost point on a vehicle front bumper to the outermost point on its rear bumper.
vehicle maintenance: Any operation that will keep a vehicle in good operating condition.
vehicle sensor: Device that detects a physical operating change of a vehicle and converts it into an electrical signal for computer use. It can also be called a transducer.
vehicle speed sensor (VSS): Sensor placed in the transmission/transaxle or the rear axle assembly. It is used by the engine's ECM to monitor vehicle speed.
vehicle tracking system: A vehicle security system, commonly monitored by a hired company, that uses a hidden miniature transmitter and receiver and the global positioning satellite system to track the location of a vehicle if lost or stolen.
vehicle weight distribution: Measurement of how weight is balanced on the front and rear tires of a vehicle.
vehicle wheelbase: Distance from the centerline of the front wheels to the centerline of the rear wheels.
vehicle width: Distance between the two widest points from the right to left sides of a vehicle body measured perpendicular to the vehicle's centerline.
vent: Louvered opening that allows air to blow into the passenger compartment.
ventilation fan: A small, low-power-consumption fan used to circulate outside air through the interior.
ventilation system: Carries fresh outside air into the vehicle's passenger compartment. One or more electric fans or blower motors force outside air through the dash ducts and vents.
vernier caliper: A sliding measuring device, sometimes with a dial gauge attached, that can make quick and accurate inside, outside, and depth measurements.
vibration damper: See *harmonic balancer.*
video camera display: In-car monitor showing the view from a small camera installed in the rear body or bumper of the vehicle. The camera captures what is behind the vehicle when the vehicle is in reverse.
viscosity: Thickness or internal friction of a fluid.
viscosity compensating valve: Diesel injection pump valve that allows for different fuel weights or thicknesses and temperatures.
viscosity number: SAE standardized numbering system used to rate oil thickness. A higher number means a thicker oil.
vise: Workbench-mounted tool with adjustable jaws that is used to hold parts during cutting, drilling, hammering, and pressing operations.
vise cap: Soft metal covers installed over vise jaws before mounting delicate parts. The covers provide extra grip while also protecting the part from damage.
volt: Unit of measurement of electrical pressure; the force that will move a current of one ampere through a resistance of one ohm.
voltage: The electrical force, or pressure, that pushes free electrons and causes current. It is also referred to as electromotive force (EMF) or potential difference.
voltage drop measurement: A measurement taken with a voltmeter that determines the internal resistance of a wire or component without having to disconnect the circuit.
voltage drop test: Type of test that can locate a part or component with higher than specified resistance without disconnecting wires or parts.
voltage regulator: Electronic semiconductor device that manages the voltage and current output of an alternator.
voltmeter: Instrument used to measure voltage (electrical pressure) in a given circuit.
voltmeter indicator: Instrument cluster display that measures voltage output of the alternator.

Copyright Goodheart-Willcox Co., Inc.

volumetric efficiency: A comparison between the actual and ideal efficiency of an internal combustion engine. The comparison is based on the actual volume of fuel mixture drawn in and what would be drawn in if the cylinder were completely filled on each stroke.

V-type engine: Engine arranged with two banks of cylinders that lie at an angle from vertical on each side of the crankshaft.

W

washer: Thin, flat "O"-shaped ring used under bolt heads and nuts to prevent the bolt or nut from digging into a part.

waste gate: A valve that vents excess exhaust gas to limit the amount of boost delivered by a turbocharger.

waste gate diaphragm: Flexible membrane that reacts to different amounts of boost pressure within a turbocharger.

waste gate diaphragm spring: Coil spring that holds a waste gate valve of a turbocharger in the normally closed position to build boost pressure.

waste gate housing: Airtight, metal container that encloses a waste gate diaphragm chamber with a pressure hose fitting to measure boost pressure.

waste gate pressure line: Hose that connects the waste gate of a turbocharger with a source of intake manifold pressure.

waste gate valve: Poppet, flap, or butterfly valve in a turbocharger that can open to bypass exhaust gases away from the turbine wheel to control boost pressure.

wasted-spark ignition system: System in which each coil is wired so that it fires two spark plugs at the same time; one plug on its cylinder's power stroke and the other plug on its cylinder's exhaust stroke (waste-spark).

water contamination: Water droplets mixing with diesel fuel to clog filters and corrode components that is a common issue with diesel engines.

water detector: Diesel injection system accessory that warns the driver of water in the diesel fuel.

water jacket: The area around the engine cylinders that is left hollow so that coolant may be admitted.

water pump: The coolant pump; any pump used to circulate coolant through an engine.

water pump bearing: Plain or ball bearings that allow the pump shaft to spin freely in housing.

water pump gasket: Gasket that fits between the engine and pump housing to prevent coolant leakage.

water pump housing: Iron or aluminum casting that forms the main body of pump.

water pump hub: Provides mounting place for the belt pulley and fan.

water pump impeller: Steel or plastic disk with fan-like blades. The impeller spins and produces pressure and flow.

water pump seal: Seal that prevents coolant leakage between pump shaft and pump housing.

water pump shaft: Steel shaft that transfers turning force from the hub to the impeller.

water separators: Feature of many late-model diesel injection systems that prevents damage from water contamination.

watt: Unit of measurement of electrical power. It is obtained by multiplying volts by amperes.

wave: An increase or decrease (fluctuation) in voltage and current. The polarity of the voltage changes from positive to negative.

waveform: The shape of a given voltage over a period of time. It can be graphed with an oscilloscope or a scan tool with a scope function.

wear bar: Solid bar of rubber across a tire tread that appears when a tire has worn significantly and needs replacement.

wear sleeve: Lubricated bushing installed between a drive axle and greased driving hub seal to limit excess friction on a front-wheel drive vehicle.

wedge combustion chamber: Combustion chamber that is shaped like a triangle or wedge when viewed from the side. The valves are placed at an angle to the top of the piston.

welder: A trained person who uses high electric current to create a high-power electric arc (voltage jumping from the electrode to the workpiece) to melt and fuse metal parts together.

wet clutch: Slip-resistant clutch submersed in transmission fluid that replaces a fluid coupling or torque converter in a transmission. Some hybrid vehicles use one or two wet clutches to control power flow to and from the motor-generator.

wet compression test: Compression test in which a small amount of oil is placed in the cylinder to determine which engine parts are causing the low compression pressure.

wet pavement test: A test that verifies the operation of the ABS electronics, as well as all mechanical parts associated with normal braking.

wet sleeve: A thick metal sleeve inserted into an engine cylinder that is constantly in contact with engine coolant.

wet-charged battery: Battery that is filled with electrolyte and fully charged at the factory.

wheel: Steel, aluminum, or magnesium frame bolted to the wheel hub that is designed to support the tire while withstanding loads from acceleration, braking, and cornering.

wheel alignment: Adjusting the suspension geometry so that all four tires roll in a straight line with full tread contact on the road surface.

wheel balancing machine: Machine that spins a tire, either on or off a vehicle, to identify locations where weights must be placed to balance the tire.

wheel bearing: Ball or roller bearing assemblies that reduce friction and support the wheels and axles as they rotate.

wheel bearing noise: A growling, hum, or rumble noise produced by a dry, worn, or damaged wheel bearing.

wheel brake assembly: Device that uses system pressure to produce friction for slowing or stopping wheel rotation.

wheel cap: A small metal or plastic cover in the center of a wheel, commonly used on aluminum wheels to hide the spindle nut and cap.

wheel cover: A metal or plastic cover that fits over the center section of a steel wheel.

wheel cylinder: Acts as the power piston, moving the friction linings into contact with the rotating drums or discs.

wheel cylinder assembly: Components that use master cylinder pressure to force the brake shoes out against the brake drums.

wheel cylinder boot: Covering that snaps into grooves on the outside of the housing to keep road dirt and water out of the cylinder.

wheel cylinder cup: Flexible rubber seal that fits in a wheel cylinder and against the piston to keep fluid from leaking past the piston.

wheel cylinder housing: An enclosure with a precision honed cylinder in it for the pistons, the cups, and the spring of a wheel cylinder assembly.

wheel cylinder piston: When the brake pedal is depressed, hydraulic pressure forces the wheel cylinder pistons apart and outward in the cylinder. The piston movement is transferred to the brake shoes.

wheel cylinder rebuild: Involves honing the wheel cylinder and replacing the rubber cups and boots.

wheel cylinder spring: Spring that helps hold the rubber cups against the pistons when the wheel cylinder assembly is not pressurized.

wheel hop: An up-and-down wheel movement caused by imbalanced or defective tire(s). The tire may skip over the road surface, causing a loss in traction and control.

wheel puller: Tool that is tightened with bolts into holes on a steering wheel to pull and remove the wheel from the steering column.

wheel runout: Wheel movement or wobble that is caused by impact damage or incorrect welding of the spider and rim.

wheel shimmy: A side-to-side wheel movement caused by imbalanced or defective tire(s). It can sometimes be caused by loose steering or suspension parts.

wheel speed sensor: Magnetic sensor used in an anti-lock brake system to measure wheel speed.

wheel weight: A small lead weight used to balance a tire and wheel assembly. It can be clipped or taped onto the wheel.

white diesel smoke: Smoke caused by unburned fuel, a cold engine, or coolant leaking into engine combustion chambers.

white engine smoke: Smoke caused by coolant leaking into engine cylinders, or, less seriously, the result of water condensation in an exhaust system.

wide band oxygen sensor: Category of oxygen sensor that can change its output gradually and in direct proportion to the oxygen content of the exhaust gases.

wide open throttle (WOT) switch: Shuts off the compressor during rapid acceleration to save power.

Copyright Goodheart-Willcox Co., Inc.

wiggle test: Physically moving wires and connectors while the engine is off or running to locate broken wires or other causes of intermittent problems.
windings: Loop of wire on a motor armature that generates a magnetic field.
window regulator: Up-down electronic mechanism for vehicle window glass.
windshield washer: Consists of a solvent reservoir, pump, rubber hoses, connections, and washer nozzles. The electric pump forces solution onto the windshield.
windshield wiper system: Vehicle system made up of a switch, wiper motor assembly, wiper linkage, wiper arms, wiper blades, and usually a windshield washer system.
wiper linkage: Set of arms that transfers motion from the wiper motor transmission to the wiper arms.
wire: A central metal conductor surrounded by plastic insulation. The type of metal conductor and insulation varies by the application.
wire code identification system: An alphanumeric method of identification that explains the color, location, and gage size of wires on a wiring diagram.
wire color code: A system for identifying and tracing specific wires throughout a vehicle based on solid colors and/or other features (stripes, bands, hash marks, etc.).
wire gage: A measurement for wire determined by the diameter or cross-sectional area of its metal conductor. It does not include the thickness or diameter of the insulation.
wire protection devices: Devices that protect wires from damage. These devices include electrical tape, plastic tubing, retainers, clips, boots, and straps.
wire stripping pliers: Pliers designed to quickly peel the insulation off metal wires.
wire wheel: Tabletop or drill-mounted circular tool constructed of individual wire metal bristles. It is used to remove carbon deposits, usually off of valves.
wireless sending unit: A device that plugs into a vehicle's diagnostic connector with the purpose of sending and receiving radio signals to and from a diagnostic tablet.
wiring harness: A group of primary wire encased in a paper or plastic sleeve. It is used to ease installation and to prevent wire damage.
wiring inspection: Process of looking for improper routing, cracked or brittle insulation, or other obvious problem signs with the wires within a vehicle.
wiring schematics: Drawings that show how the wires connect to each component in an electric or electronic circuit. Symbols represent components, and lines represent wires. They are also called wiring diagrams.
wiring splice: The place where two or more wires are connected.
wood alcohol: See *methyl alcohol*.
work: A force applied to a body, causing it to move. It is measured in foot-pounds, watts, or joules.
work order: Form used by a technician to describe vehicle problems and to record diagnosis and repairs. It is also often used as a customer invoice or to prepare a repair estimate.
worm shaft: Shaft connected to a worm gear in a worm-type steering gearbox.
worm-and-roller steering gearbox: Gearbox that contains a roller that is mounted on the sector shaft and meshes with the worm gear. The free-turning roller reduces internal friction.
worm-drive hose clamp: Type of hose clamp that uses a worm gear that engages slots in the clamp strap to allow tightening around the hose.
worn idler arm: Damaged or overly worn idler arm in a linkage steering system that causes the front wheels, especially the right wheel, to turn without any steering wheel movement.
worn universal joint: A deteriorated and dry universal joint that is a common problem for vehicles with a drive shaft. A driveline clunk, vibration, or deep-pitched thud noise upon release of the accelerator can warn of this problem.
wrench: Handheld tool used to grip and turn nuts and bolts for installation or removal.
wrench size: Specific standard (inch) or metric (millimeter) measurement taken across the jaws of a wrench. The size of a wrench is stamped on its side.
W-type engine: Engine arranged similar to a V-type engine in that it has two banks of cylinders, but the cylinder bores in each bank are staggered.

Y

yardstick: A straightedge measuring tool used for linear measurements up to one yard (three feet) or one meter. Inches are marked on one side of the rule and metric marks are shown on the other side. It is also called a meter stick.
yaw sensor: Part of a stability control system that measures the direction of the thrust generated by vehicle movement.

Z

zener diode: A silicon diode that serves as a rectifier. It allows current to flow in one direction only until the applied voltage reaches a certain level, then the diode allows current to flow in the opposite direction.
zero resistance: Description of a perfect electrical path between two test points. There is continuity and a resistance of zero in the tested circuit or component.
zero valve lash: Term for no clearance in a valve train. Hydraulic lifters are able to automatically adjust valve clearance in engines with zero valve lash.
zirconia oxygen sensor: Type of oxygen sensor that uses zirconia and platinum to produce a voltage output that represents oxygen content in exhaust gases.
zone clearing defogger: Used on rear windows to heat and clear one area of the glass (usually the center) before another.
